THE popularity of this little monograph on the experimental surgery of the respiratory system has been demonstrated by the early appearance of a second edition. We do not note any material change from the former volume. We again take the opportunity to congratulate the worker and writer in this interesting field of surgery.

Laboratory Directions for Beginners in Bacteriology.

An Introduction to Practical Bacteriology for Students and Practitioners of Comparative and of Human Medicine. By VERANUS A. MOORE, B. S., M. D., Professor of Comparative Pathology and Bacteriology, New York State Veterinary College, etc. Second Edition, Enlarged and Revised. Pp. xvi-143. Boston: Ginn & Company, 1900.

THE second edition of Dr. Moore's little work is amplified and extended by embracing the newer facts in bacteriology. The directions for carrying out laboratory work and for following systematic lines of study are clearly and logically given, and as we read, for instance, the chapters on making culture media and on making cultures of the various organisms, we are struck by the excellence of the didactic method. For an elementary text-book on bacteriology, we know of none better than this.

Medical Electricity. A Practical Handbook for Students and Practitioners. By H. LEWIS JONES, M. A., M. D., Medical Officer in Charge of the Electrical Department in St. Bartholomew's Hospital, etc. Third Edition. With Illustrations. Pp. xv-532. London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$3.]

THE third edition of this work is an interesting volume. Much has been added to it, especially in the chapters dealing with the special uses of electricity in medicine and surgery. The Röntgen rays are fully discussed, and besides the general uses of these rays in the detection of foreign bodies and in studying osseous lesions, the author believes that they will be found of the greatest value in the diagnosis of diseases of the heart and lungs. There is probably no better manual on the subject than this well-known work.

A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By ARTHUR R. CUSHNY, M. A., M. D. Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan, etc. Second Edition, Revised and Enlarged. Illustrated with Forty-seven Engravings. Pp. v-7 to 732. Philadelphia and New York: Lea Brothers & Company, 1901.

OWING to the fact that but little more than a year has elapsed since the first appearance of this work, it is not to be expected that a second edition should show material change or alteration. With the exception of a few additions upon recently introduced preparations and an occasional minor revision, the book remains unaltered. Of the high quality of the book we have heretofore spoken, and that the first edition should have been so rapidly exhausted occasions us no surprise.

Diseases of the Throat, Nose, and Ear. A Clinical Manual for Students and Practitioners. By P. Mo-

BRIDE, M. D., F. R. C. P. Ed., Fellow of the Royal Society of Edinburgh, etc. Third Edition, Revised and partly Rewritten. With Colored Illustrations from Original Drawings. Pp. xvi-744. Edinburgh and London: Young J. Pentland. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$7.]

WE have long considered McBride's treatise one of the best works on these special topics. He has, to a rare degree, the art of intelligent condensation, and has furnished us with a vast amount of information, well digested and so arranged as to be available with the least possible search. As stated above, the work has been partly rewritten and brought down to the present time. In fact, as we have looked through the volume, we have found mention of practically every matter of moment which the advances made in these special lines during the last few years have brought into prominence. The illustrations are notably good and give a very definite idea of the various lesions seen in actual practice. The author has very positive views on treatment, and, while he shows a thorough acquaintance with the voluminous literature of the last decade, does not leave his reader in any doubt as to his own convictions. The work is to be unhesitatingly commended.

Miscellany.

Solidified Air.—A report comes in a special to the *New York Times* that Professor A. L. Metz, of Tulane University, has succeeded in making a small block of solidified air which was as substantial (for the time being) as a block of ice. It was about an inch in diameter, and lasted about fifteen minutes in a fully exposed condition. He laid it on an anvil, and as he struck it the hammer bounded off as though it had been a piece of rubber. It was so intensely cold that no one could think of touching it with his fingers. Taking a large test tube, about eighteen inches long and over an inch in diameter, Professor Metz put liquid air into it, filling it to within six inches of the top. He then corked it, and through the cork inserted a bent glass tube which was connected with his vacuum apparatus, the full power of which was applied in order to induce the most rapid evaporation possible. The liquid air boiled and bubbled as though it had been suddenly exposed to the most intense heat. When thus exposed to extremely rapid evaporation, its temperature dropped very rapidly. The cold produced was so intense that the atmosphere in the immediate neighborhood of the test tube began actually to liquefy and drop from the lower extremity of the tube. It was caught in a Dewar test tube and found to possess all the characteristics and properties of liquid air. In the meantime the volume of air remaining in the tube was found solidified in a lump a little more than an inch deep. In order to extract this it was found necessary to break the test tube, when the lump of solid air was fully exposed to the action of the atmosphere.

"Doctors by Enactment."—The *New York Tribune* for March 29th says that when it recently protested against "the mischievous proposal to admit men to the bar by act of legislature, without the requirements of legal study and examination," it quoted as inevitable the logical conclusion that on the same principle a man would be equally entitled to be admitted to practise medicine in the same way, viz., by political pull and without

study. It now finds that what it cited as a *reductio ad absurdum*, "not supposing any one would ever have the temerity to pursue such a course," is actually being attempted, and comments upon this pitiable fact in the following appropriate terms:

"It is high time to call a halt upon this transformation of the State Capitol into a bogus diploma factory. Since laws regulating admission to the professions have been enacted, they should be enforced and maintained. If men want to practise law or medicine they should prepare themselves to do so by means of the legally prescribed courses of study, which are open to all fit persons on the easiest of terms. If they complete those studies and acquire the prescribed preparation they will get their degrees and licenses as a matter of course without special legislation. If they are not capable of pursuing the studies, and are not competent to gain the prescribed preparation, they have no business to seek entrance to the professions. The world is wide. There are other useful and honorable callings open to them without their seeking to intrude into professions for which, by their own confession, they are not adequately fitted."

A Pan-Hellenic Medical Congress is to be held in Athens from May 6th to 10th, and its success is considered as already assured by the wide adhesion that it has received among Hellenic physicians. All Greek physicians who may not have received the invitation and programme are requested to communicate with Dr. Michael Mangakis, Rue de l'Université, No. 85, Athens. Foreigners are permitted to take part in the proceedings if they have given in their adhesion to the congress and forwarded the subscription, which has been fixed at fifteen drachmas (three dollars). The following subjects are fixed in advance for discussion: 1. Phthisis and Sanatoria in Greece; Professor N. Maccas, of Athens, and M. B. Patrikios, of Athens. 2. On the Use of Alcoholic Beverages in Greece and its Effects; M. J. Foustanos, of Syra, and Professor G. Vaphas, of Athens. 3. Continued Fevers in Greece; M. J. Cardamatis, of Athens, and M. J. Théophanidès, of Agrimon. 4. Lepra; Professor M. Hadjimichalis, of Athens, and M. F. Mitafsis, of Athens. 5. Echinococcus; Dr. Clado, of Paris, and M. S. Tsaconas, of Athens. 6. School Hygiene; M. C. Papagiannis, of Athens, and Professor G. Vaphas, of Athens. 7. Appendicitis; Dr. N. Alivizatos, of Athens; Professor J. Galvanis, of Athens; Dr. G. Phocas, of Lille, and M. A. Psaltoff, of Smyrna. 8. The Surgical Treatment of Tuberculosis; Dr. Clado, of Paris; Professor J. Galvanis, of Athens, and Professor Spiridion Manghinis, of Athens. 9. Asepsis and Antisepsis in Greece; Dr. Catérinopoulos, of Athens. 10. Dystocia from Pelvic Defects; Dr. T. Campanis, of Athens, and Dr. C. Digénis, of Athens. 11. Lesions of the Eyes in Infectious Diseases; Dr. N. Dellapoytas, of Athens, and Dr. T. Metaxas, of Athens. 12. Syphilis in Greece; Professor M. Hadjimichalis, of Athens.

Relations between the Nose and the Female Sexual Organs.—A. Schiff (*Wiener klinische Wochenschrift*, 1900, p. 58; *British Medical Journal*, February 16, 1901) discusses this subject. Fliess in 1897 published a book with this title, in which, after restating the fact that in menstruation there regularly occurs swelling and congestion of the nasal lining, he says that this change affects two special points, the front end of the lower turbinate and the tuberculum septi, which are not only swollen, but specially sensitive. These he calls the genital spots. These points have special relations to the

pain in those dysmenorrhœas which do not end with the onset of the flow, and the pain can be stopped by cocainizing these points, hypogastric pain by the turbinate, and sacral pain by the tuberculum. Starting from a skeptical standpoint to test these statements, Schiff ended by being convinced of their absolute accuracy. His cases were got from the clinics of Schroetter and Chrobak, and were carefully selected by excluding all in which the pain was erratic and did not regularly continue for whole days at each period, and he was very careful in avoiding any possibility of "suggestion." He painted the genital spots during the pain with twenty-per-cent. cocaine solution, and of forty-seven cases he could regularly produce cessation of the pain in thirty-four. Some cases he observed for months and had more than two hundred positive results with cocaine. So little cocaine was used that there was no question of a constitutional effect, and he got the same result with three to five per cent. solution if he first contracted the nose lining with suprarenal extract. The pain, hypogastric and sacral, could be painted out bit by bit by taking the genital spots in succession. In seventeen of the positive cases he, in the menstrual interval, cauterized the genital spots with trichloroacetic acid or electrolysis, and twelve had no return of the dysmenorrhœa, three being under observation as long as from one and a half to two and a half years. In the other five, he thinks the cauterization was probably not complete. Of the thirteen negative cases, nine had been examined gynæcologically, four had fixed retroflexion, two adnexal disease, and one parametritis. Two with normal pelvic organs had marked hysteria. Of the thirty-four positive cases, twenty-four had been examined; nine had approximately normal organs and fifteen marked pelvic disease, mostly inflammatory. Many of the cases had been under gynæcological treatment. Perhaps the strongest confirmatory evidence of the constancy of the relation of the genital points of the nose to the pelvic pain was given by a series of experiments, beginning with the following observation made on the first patient treated from Chrobak's clinic. The woman had a large adnexal swelling on the left, and when in the presence of several of the staff he touched the left turbinate with the cocaine plug, she, without knowing what he was looking for, said, "That hurts me so down here," pointing to the left hypogastrium. This was repeated each time, but with the addition that it was not so sore, till the anæsthesia was complete. A second patient, on whom Chrobak had a week before done a ventrofixation for fixed retroflexion, had severe hypogastric dysmenorrhœal pain. When the right turbinate was touched she cried out, "I feel that down here. That hurts so much down here," pointing to the right hypogastrium. The left side gave like results, and when the tuberculum septi was touched she called out loud, "My back, my back!" She had otherwise no sacral pain. This experiment was repeated by Schiff and by several others, and gave constantly the same results. The details of two other like cases are given, and of sixteen women twelve regularly gave these results. In the intermenstrual period this phenomenon could not usually be elicited, but in a few cases with intermenstrual pain it could be got. The importance of this point, especially in the dysmenorrhœa of virgins, is considerable, and in particular the cocainization may be used as a test of the nature of the dysmenorrhœa. The application must, of course, be made exactly by exposing the genital spots by a speculum. Fliess had pointed out a corresponding relation between the anterior end of the left middle tur-

binate and certain gastralgiæ, and Schiff was able to confirm this by several observations.

The Borderland in Mental Disease.—Dr. G. W. Balfour (*Edinburgh Medical Journal*, February), in the Morison lecture for 1900, delivered at the Royal College of Physicians of Edinburgh, says:

"This cursory review of sporadic and of epidemic insanities is fraught with several lessons; first, it teaches us that insanity is a disease of which no one need be ashamed, as some of the finest minds in all ages have similarly suffered. It is not a disease of the mind or intellect, but only of that organ—the brain—by which our minds are able to communicate with our fellow-men. And we must always remember that this brain trouble is very often only functional, and not organic. This means that it is curable if early and properly treated. But we know from the history of functional ailments in other organs, that, if neglected at this stage, a curable affection is apt to become incurable, and even at the best the affected organ becomes so ill-nourished and enfeebled that much time and much care are required to restore it to its former healthy condition. As the brain is the organ of thought, when ill or enfeebled, whatever excites it injures it, and it is often necessary to remove such patients from their homes for the sake of securing perfect quiet and the absence of any irritating influences, and very often much harm results from undue delay in having recourse to this most beneficent and most needful form of treatment. It should never be forgotten that the harm that may result is not merely postponement of recovery, that is certain, but it may even amount to a permanent weakening of the brain.

"The second lesson to be learned is that, as the great object of all education is to enable us to control the emotions and passions, and to regulate the imagination by the cultivation of the faculties of judgment, comparison, and attention; and as whatever tends to emancipate the lower powers of our nature from the wholesome control of our judgment and our will is injurious to our intellectual well-being—we ought to shun all forms of mental excitement, under whatever names they present themselves, which tend to enfeeble our will, or to rouse the emotions and kindle the passions at the expense of those powers which have been given us for their regulation and control, assured that no form of even a minor mania has ever passed over the surface of society without leaving behind it many sad traces of its injurious action."

Osteomalacia.—M. Gayet and M. Bonnet conclude an article in the *Revue de chirurgie* for February as follows: 1. Osteomalacia is a trouble of nutrition of the bones consisting in a deficiency of lime salts and leading to softening of the skeleton. This trouble may be local or general. 2. Local osteomalacia is observed to follow traumatism, osseous infections, and also certain nervous diseases. 3. The anatomical lesions are similar in the local and the general forms. They are not uniform, but present varieties which are not in any relation with the seeming ætiology, the clinical variety, or the degree of generalization of the disease. 4. The pathogenesis has no specific character. 5. There are predisposing causes evident, related to age, sex, climate, etc. 6. The determining causes remain obscure, but the totality of facts seems to assign the greatest place to troubles of the nervous system. 7. A plausible explanation of the satisfactory effects of castration is found in the fact that the internal secretion of the ovaries results in increased activity of the elimination of phosphates.

Original Communications.

THE EARLY DIAGNOSIS OF
ECTOPIC GESTATION.*

By ANDREW F. CURRIER, M. D.,

NEW YORK.

THERE are few, if any, of the grave morbid conditions to which the generative organs of women are susceptible which have been more carefully investigated and are more thoroughly understood at the present time than is the tremendous accident which is known by the term *ectopic gestation*. The term is a vague and unfortunate one, and is about as accurate in defining the condition which it is supposed to indicate as that other unfortunate term *vicarious*, which is supposed to apply to an unusual form of menstruation. Both terms should be discarded if we feel any concern for scholarly precision in our medical nomenclature. A gestation which is *out of place*, if we analyze the word *ectopic*, may mean almost anything. This want of accuracy in the use of terms is the more noteworthy since our clinical experience, if it has taught us anything, has taught us that gestation must take place primarily either within the uterus or within that duct which bridges the space between the ovary and the uterus.

Primary gestation within the ovary or within the pelvic or abdominal cavity, if it occurs at all, occurs so rarely as to be in an extreme degree exceptional, and *exceptio probat regulam*.

I shall therefore assume that the proposition is not disputed that ectopic gestation in the present discussion means gestation within any portion of the Fallopian tube. This includes, of course, that rare form in which the product of gestation is partly in the tube and partly in the uterus, as well as the form in which it is partly in the outer extremity of the tube and partly in the pelvic cavity.

The form of pregnancy which is commonly known as interstitial, while unusual and dangerous, is, strictly speaking, uterine, and should be discussed from that standpoint. We must also eliminate from this portion of the discussion that form of tubal disease known as hæmatosalpinx, or tubal hæmatoma, which simulates tubal gestation by the profuse hæmorrhage by which it is often characterized, this condition forming the theme for another participant in the present discussion.

The question which I am to approach may therefore resolve itself into the diagnosis of tubal gestation during its first three months. Rupture of the tubal tumor usually occurs within that period, and subsequent to that period there are, as a rule, few pronounced symptoms which are the source of great disturbance until the growing fœtus has reached maturity. It is therefore a matter of the greatest importance to the woman who is thus afflicted that her condition be diagnosticated during these

three critical months. If the diagnosis of tubal gestation is determined within the period mentioned, but one course of action is indicated, in my opinion, and that consists in the removal of the cause of the disturbance by abdominal section. It is generally recognized and admitted that gestation may occur in either tube or in both, and in both tubes either simultaneously or consecutively. It may also be initiated in any portion of the tube. As gestation progresses, the entire structure of the tube is usually involved, except when its seat is the fimbriated extremity. An early abortion usually terminates that form of gestation. The distinction as to the portion of the tube which is involved cannot usually be made until the abdomen is opened, nor is it essential to make such a distinction. The mere fact that tubal gestation exists, is a sufficient motive for such a course of action as will unquestionably bring prompt and certain relief, for this is one of the destructive conditions in which, as it seems to me, we can never be justified in assuming that any change for the better will result from delay.

The symptoms which determine the diagnosis of tubal gestation may be divided into the ordinary and the extraordinary. The ordinary symptoms are those which belong to gestation under ordinary, or normal, conditions; the extraordinary are those which are peculiar to this form of gestation.

Of the ordinary symptoms, one has only to recall the enlargement of the breasts with increased prominence of the veins and enlargement of the papillæ in the areola which surrounds the nipple—symptoms which are often overlooked—the bluish discoloration of the vaginal mucous membrane, and softness of the tissues of the vagina and uterus, in which the impression received by the examining finger is totally different from that which is obtained when gestation is absent.

To these may be added non-appearance of the menses, irritability of the stomach, with possible nausea and vomiting, increase in the size and change in the contour of the uterus, increase in the secretion of the glandular structures of the vagina and uterus, etc.

All these symptoms are familiar enough during the first three months of normal pregnancy, becoming determinable during the second month, and well accentuated during the third. As some of them are not of unvarying occurrence, the physician may be misled by the absence of one or more of them, and he may fail to detect gestation until it has proceeded so far that its detection is almost inevitable.

The point which I desire to make at this time, one which I have never seen emphasized elsewhere, is that when gestation occurs, be it normal or abnormal, it produces certain changes in the tissues and in the general condition of the patient which are characteristic of the pregnant state, which make the pregnant state a class by itself, and which make the latter the primary object to be determined by an examination. The fact that these changes are in most cases inconspicuous during the first

*Read before the Obstetric Section of the New York Academy of Medicine, March 28, 1901.

month renders them relatively indecisive in determining a diagnosis, whether the gestation be normal or abnormal, but the further the progress from this initial period the more pronounced are the changes which have taken place, and they should be carefully sought for and given due weight in deciding as to the existence of gestation and as to its normal or abnormal nature.

The extraordinary signs or symptoms should be regarded as confirmatory of the ordinary. They should teach us not only that gestation is present, but that it is present in a form which should excite alarm and call for immediate and radical methods of procedure. They are the complete antipodes of the ordinary signs. The latter incline us to quiescence, to the entire surrender, for the present at least, to the amply protective forces of Nature; the former command us in tones most imperious to interfere and correct the mistakes and the inefficiency of Nature.

There are certain conditions of the pelvic organs which seem to predispose to tubal gestation, and their ætiological importance should be considered in arriving at a diagnosis. Such are retroflexion of the uterus, precedent sterility, disease or dislocation of the Fallopian tubes, a bicornate structure of the uterus, precedent tubal gestation, etc. There are doubtless others, but these are the ones with which my experience has familiarized me.

In one of the first cases which came under my observation, many years ago, the patient had been sterile, and had been treated for months by an experienced gynecologist for retroflexion. There was no suspicion of pregnancy, and when I saw her, a few days before her death, the retroflexion was palpable enough, but I failed to discover the fœtus, which had developed within the abdominal cavity. Rupture of the fœtal sac, peritonitis, and death soon followed, and the autopsy revealed a mature child within the abdominal cavity, the presence of which had apparently been most remote from the minds of the several physicians who had been watching the case.

Twisting or distortion of the Fallopian tubes, fixation by adhesions in unusual situations, inflammation of the tubal mucous membrane, have all furnished numerous examples of the possibility of tubal gestation in connection with such abnormal conditions.

Of tubal gestation in a bicornate uterus, I have seen but one example, the gestation being in the proximal third of the right tube, which was twisted outside, or beyond, the tumor. Rupture of the tubal sac had occurred and bleeding was in progress when I performed the operation. The diseased tube and its ovary were removed, and pregnancy with normal delivery has since occurred in the left cornu. A sterile period of twelve years intervened in this case between the tubal pregnancy and the previous normal one.

A tubal gestation occurring the second time in the same individual is, of course, a rare occurrence. The degree to which a sufferer from one occurrence of this kind is susceptible to another, I do not know. Not a few

instances are on record in which this form of gestation has been repeated.

One such case has come under my observation. While the patient was in collapse from internal hæmorrhage in her first gestation she was seen by a gynecologist, who, I was told, believed her so near death that he declined to operate upon her. She rallied, however, and two years later experienced tubal gestation the second time. I saw her after she had suffered repeated hæmorrhages and was already septic. The diagnosis was clear enough, but, recalling her previous experience, she declined an operation, she and her husband both declaring that they would assume all responsibility. Ten days later, after several additional hæmorrhages and increased evidences of septic intoxication, I was permitted to operate, and removed a beautiful specimen, which was still within its tubal envelope. The absence of the ovary upon the unimpregnated side and the encasement of the tube in a bed of dense adhesions confirmed the story of the precedent gestation. Anything but a fatal issue could hardly have been expected, in view of the long continuance of the septic condition. Death resulted on the sixth day. These predisposing factors must, therefore, be taken into account in reaching a conclusion as to the presence or absence of tubal gestation.

The extraordinary signs of tubal gestation, like the ordinary signs of normal gestation, are not always present, or always present at the same period, or always of equal intensity and significance. A single one of them may be convincing and determine immediate action, or several of them may leave one in doubt and uncertainty, which can only be dispelled by delay or by an exploratory incision.

By all odds the most important and the most convincing of the extraordinary signs is hæmorrhage. Seldom is the bleeding external or manifest; it would be unreasonable to expect that such would be the case, for the tension of the pelvic current is reduced to a minimum by the outflow from the ruptured vessels. Hæmorrhage is most likely to occur, and occurs most early, in those cases in which the seat of the gestation is the fimbriated extremity of the tube. It is least likely to occur when the oval sac is near the middle of the tube. The abundant blood supply of the broad ligament, tube, and ovary, and the comparative absence of contractility of the loose and delicate tissue in which the vessels are located, explain the profuseness of the hæmorrhages and their frequency. I have seen the belly filled with blood and hæmorrhage still in progress, though the patient had already been in a state of collapse and had rallied from it. A fœtal sac at the fimbriated end of the tube seldom progresses to the end of the first month without rupture, and, from the nature of the case, the hæmorrhage is frequently fatal. This is sometimes due to the fact that the comparative absence of a tumor misleads the physician as to the gravity of the case, and he temporizes until the time for effective surgical intervention is passed.

In any portion of the tube except the fimbriated extremity rupture is usually observed between the sixth and twelfth weeks, and the signs of hæmorrhage coming at such a time would usually exclude the fimbriated, or terminal, variety.

By rupture we do not necessarily mean the complete rupture of the foetal sac, with escape of its contents. The pressure of the growing ovum may be sufficient only to tear the distended tissue of the tubal wall by which it is surrounded, with accompanying rupture of the blood-vessels which it contains. This may be repeated several times, as I have seen in a number of cases. Or the expansive force may be sufficient to rend the foetal sac, expel its contents, and land the foetus between the folds of the broad ligament, among the loose and mobile intestines, or at the bottom of Douglas's cul-de-sac. I have found one foetus of the fourth month of development lying free in the last-mentioned location. The signs of hæmorrhage from tubal rupture are not easily mistaken; the weakness of collapse, the flickering pulse, the pinched face, and the shallow breathing can have but one significance.

Next in importance to bleeding as a diagnostic symptom is pain. It is not always present, it is usually paroxysmal, it is sharp and darting, and inclines the patient to relax the muscles of the thighs, and flex the thighs upon the abdomen. It is often associated with hæmorrhage, but I doubt whether this is always the case. Whether it is due to the stretching of the peritonæum or to its rupture, or to both, is not quite clear, although it is generally observed that the perforation of the peritoneal covering of any structure or organ causes acute pain. It may be the leading feature in a rapidly developing peritonitis with considerable abdominal distention. I recall such a case seen late at night in consultation, the distention being too great to permit abdominal palpation. Unfortunately, this woman was not again seen by a gynæcologist. She died very suddenly two days later, and the autopsy disclosed an unbroken tubal sac with a pedicle no thicker than one's finger, a perfectly ideal case for successful operation.

The third diagnostic point consists in the presence of a pelvic tumor. It is usually best determined by examination *per rectum*, the patient's thighs being flexed upon her abdomen. In most cases an anæsthetic is essential to success in such an examination. By the bimanual palpation through the relaxed abdominal walls the dimensions and location of the tubal mass, and its relations to the uterus and other pelvic structures, can usually be readily outlined. These three symptoms—hæmorrhage, pain, and tumor—are the most important of the extraordinary symptoms, and the most constant. If a diagnosis cannot be reached with these and the ordinary signs of pregnancy, the fault will probably lie with the examiner.

The passing of decidual membrane by the vagina, hæmorrhage from the uterus, pulsation of the vaginal

arteries, and various other signs are all of minor importance. They doubtless have impressed individuals in particular cases, but they must not be regarded as of unvarying appearance or of undoubted importance.

Many cases are not seen by the gynæcologist until there have been repeated hæmorrhages, decomposition, septic absorption, and perhaps numerous unnecessary and unskilful attempts to find out the cause of trouble. This is tampering with precious opportunities. The patient is finally brought to the notice of the gynæcologist with a sallow and leaky skin, a rapid pulse, a dirty tongue, and other evidences of profound septic intoxication. The resources of surgery are of little avail for such cases. I recall a case in which, after hæmorrhage and collapse, the uterus was curetted and perforated. Another physician tapped the vagina and drew off a large quantity of blood. When the patient seemed ready to drop into the grave with sepsis and anæmia, I was asked to see her, and consented to operate, but with little hope that it would be of any use. The uterus was first removed and then the diseased appendages, and, strange to say, the woman recovered. I doubt whether one is justified, as a rule, in operating in these extreme cases, except with the clear understanding that it is only as a last resort.

The diagnosis of tubal gestation is not always conclusive even when the abdomen is opened, a tumor of the tube discovered, and a quantity of blood found in the abdomen or pelvis. Many errors of this kind have been made. The operative procedure may have been clearly indicated, but the case is not one of tubal gestation unless the foetus is found within the tube or without the tube, or unless the microscopical examination of the tubal mucous membrane reveals the presence of decidual cells. Without a decidua, whether within the uterus or within the tube, there can be no gestation.

With the familiarity which has been gained by abundant experience with this form of a grave accident, there is now little excuse that a fatal issue should occur until at least an attempt has been made to recognize the situation and use all proper means to bring it under control.

130 EAST THIRTY-SIXTH STREET,

THE USE OF HOT-WATER VAGINAL INJECTIONS.*

BY JAMES HAWLEY BURTENSRAW, M. D.,
NEW YORK,

LECTURER ON OPERATIVE GYNÆCOLOGY IN THE NEW YORK POLY-
CLINIC MEDICAL SCHOOL AND HOSPITAL.

THE local use of hot water in the treatment of pelvic diseases of women probably antedates the erection of the pyramids. In spite of this fact, I venture the assertion that no therapeutic measure is so frequently misapplied, so thoroughly abused, so imperfectly under-

*Read before the New York County Medical Association, November 19, 1900.

stood as the hot-water vaginal injection. Employed conscientiously and in accordance with the rules of common sense, it is one of the most valuable remedies at our command; employed, as it is in ninety-nine cases out of a hundred, it is capable of doing infinite harm. Its misapplication in almost every case is the fault of the physician, whether general practitioner or gynecological specialist. It is a remarkable fact that therapeutic douches are so generally prescribed without an intelligent idea of how they accomplish good. That they act favorably in most inflammatory conditions of the pelvis is well known, but that is as far as the average practitioner inquires into the matter, and his patient suffers in consequence.

It is by no means unusual to learn from a patient that she has been employing hot-water vaginal douches for months, or even years, without appreciable benefit. Indeed, it has but too frequently been my experience to hear that, after persisting a few weeks or months in the treatment, the patient has actually felt worse, and has discontinued them. Sifting the information gleaned from these patients, of both classes, one readily arrives at the cause of failure. In the first place, the physician's directions have been indefinite regarding almost every detail of the douche, and the patient, for the most part, has been compelled to exercise her own judgment. On her part, the failure is to be attributed to one of several causes. Has she assumed a recumbent position when taking the douche, and has she used the water at as high a temperature as could be borne? She may answer in the affirmative, and then, when asked how much of this hot water she has used at each injection, she will answer "one quart!" Another patient will say she has used a much greater quantity of very hot water, but has squatted over a douche pan or sat at ease on a toilet while taking an injection. A third has lain flat on her back and has used a gallon or more of water of only moderate temperature; a fourth has possessed some knowledge of the proper method to employ, but has followed the treatment in very irregular and spasmodic fashion—and so it goes. The intention has been of the best, the practice of the worst.

The principles underlying the rational application of the hot-water vaginal injection are very simple. In the first place, the distinction between a cleansing douche and a douche taken for its therapeutic effects should be borne in mind. The former every intelligent woman will employ as often as her sense of cleanliness dictates, and the amount of water used may be small and of a temperature comfortably warm, but the therapeutic douche has a certain remedial duty to perform, and this may be done only in a certain way.

The initial effect on the tissues of water at a temperature of from 105° to 120° F. is to dilate the contained blood-vessels and thus cause congestion, or to increase that which may already be present; the secondary effect is that of contraction and consequent lessening of

the congestion, the excess of blood being driven out. The writer well remembers the manner in which this was illustrated by the late Dr. Goodell. He said: "Plunge your hands into very hot water and keep them there four or five minutes. Then take them out, and they will be red and puffed up. If you wear a ring, you cannot get it off the finger. Then immerse your hands for fifteen minutes in this very hot water, and what happens? They become pale and shriveled, veritable 'washer-woman's hands,' as a result of the secondary or constricting effect of the hot water."

It is exactly this result which one should aim to bring about in the treatment of inflammatory conditions of the pelvic contents by the use of hot water. At the best, the conformation of the vagina allows the fluid to come in contact only with the cervix and vaginal walls, but, through the medium of the contained blood-vessels and nerves, the heat indirectly but markedly affects the circulation of the entire pelvis, either for good or for evil, according to the manner in which the application is made. I cannot conceive of a greater error than that of prescribing a two-quart hot-water vaginal douche for any purpose whatever, other than that of producing pelvic congestion or preserving cleanliness, nor can I appreciate the carelessness of the physician who neglects giving specific directions as to how the douches should be taken. Two quarts of water will pass through a fountain syringe to which an ordinary tube and vaginal nozzle are attached in exactly two minutes, the bag of the syringe being two or three feet above the point of exit. To my mind, it is preposterous to imagine that such a brief application of heat can do more than add to the congestion that is already present in the pelvic vessels, and therefore do great harm. Let one immerse his hands for that length of time in water heated to a temperature of 115° F., and note the result. Nor is greater good accomplished by the four-quart douche, but rather more harm, in a majority of cases, if not all.

In those cases in which the therapeutic douche is indicated, I give the patient a printed slip containing rules to be observed in taking the injections, cautioning her that the directions must be followed to the letter. A copy of these follows:

1. Use a large-sized fountain syringe or douche can attached to a support three or four feet above the body.

2. Always lie flat on the back when taking a douche, with the hips slightly elevated and the shoulders depressed.

3. Always use at least *three gallons* of plain water as hot as can be borne (at a temperature of from 107° to 120° F.) for each douche.

4. Take the injection twice daily, morning and evening, except on the two days preceding and the two days following the menstrual period, when it should be omitted.

5. Rest for half an hour or an hour in a recumbent position after taking each douche.

For my clinic patients, these directions are printed in English, French, Italian, German, Polish, Russian, and Yiddish.

In recommending the use of such a large quantity of hot water for each douche, I am perfectly well aware that it is in opposition to the accepted teaching of many authorities; nevertheless, I am convinced that a careful study of the subject will demonstrate the soundness of my contention. I do not lose sight of the fact that in some instances, in which it is desired to *increase* the amount of blood in the pelvic blood-vessels, the vasodilating action is best accomplished by the administration of moderate-sized douches, but these cases are much less frequently met with than those of pelvic inflammation, in which the large douches do so much good.

The frequent filling of the fountain syringe in order to use so large a quantity of water is inconvenient and wearisome, and, therefore, I usually suggest the substitution of an ordinary pail for the bag, the water being conducted from it by siphonage, or, better, through a short pipe inserted in the side close to the bottom. If household conveniences permit, a Y-shaped arrangement of tubing may be attached to the hot-water and cold-water faucets of a bathtub, and the temperature of the outflowing water regulated at will, the woman lying on her back in the tub and allowing the irrigation to continue for fifteen or twenty minutes. A hard-rubber vaginal nozzle, perforated at the sides rather than at the end, is to be preferred in taking these douches, so that the water may be projected laterally rather than directly on the cervix.

The question of how to dispose of the large quantity of water flowing from the vagina during the progress of douche-taking is of considerable moment, and, perhaps, it is inability to decide this point satisfactorily which influences so many women to take the douches improperly. An ordinary douche pan is entirely too small to collect all the water used, and a larger receptacle is out of the question on account of its use necessitating a change in the position of the body, making it practically impossible for the patient to remain in a recumbent position. A douche pan having a waste-pipe attached is sold by certain manufacturers, but it is inconvenient to use, because the point of exit of the water must be on the same level as the pan itself, or lower, which usually necessitates the taking of the douche while lying on a bed or couch. Lying on a bed with the feet supported by chairs placed at the side, a gathered rubber sheet conducting the water into a proper receptacle on the floor, is a plan that is not commended. The shoulders of the patient are apt to be above the hips in this position, and the bed or floor, or both, almost surely become wet. By all odds the most convenient method to adopt is that of taking the douches in a bathtub, provided, of course, it is of sufficient size. A couple of bricks covered

with oilcloth will serve to raise the hips sufficiently, but a tightly-rolled blanket is better, as it prevents the water from flowing toward the head of the tub, and so keeps the body dry. In the case of dispensary patients, I have frequently suggested the use of an ordinary wooden washtub, two boards being stretched across it a couple of inches apart, upon which the woman lies flat, her legs being flexed, and the waste water finding its way into the tub between the boards.

The size of the tube leading from the syringe, the size and number of the orifices in the nozzle, and, to some extent, the capacity of the patient's vagina, bear importantly on the conditions governing the douche. Thus, if the tubing and nozzle orifices are larger than those ordinarily used, although the proper amount of water may be employed, it may be too quickly exhausted and the congested condition not relieved. If the vaginal walls and perineal body are much relaxed, or the latter is the seat of a marked laceration, unless the hips are maintained in a raised position the water is apt to drain off too quickly.

The three-gallon hot-water douche is of special value in cases of acute or chronic metritis, in subinvolution, in perimetric inflammation, and in perimetric and parametric exudations. Ovarian pain will frequently yield to it in a surprisingly satisfactory manner, while the bearing-down sensation and pain in the back, concomitants of disorders of the pelvic organs, very quickly disappear. A troublesome leucorrhœa, in a majority of instances, will be checked after a very few applications of the douche, due, of course, to the consequent toning up of the vaginal and uterine mucosa. In addition, my experience has been that, in the case of debilitated women, in whom the pelvic condition is not of sufficient gravity to demand special attention, these douches act as a general systemic tonic and are a valuable adjunct to other methods of treatment.

As a rule, I direct that the water be used without the addition of any medicament whatever, but, if the accompanying leucorrhœal discharge is profuse, I order a tablespoonful of the following mixture to be added to the last quart of water remaining in the douche-bag at the termination of the injection:

R	Powdered alum,	}	each. 1 ounce;
	Zinc sulphate,		
	Sodium bichlorate,		
	Carbolic acid,		
	Water.		6 ounces.

M.

This combination is cleanly and non-irritating, and acts admirably in selected cases. The addition of a small quantity of ordinary table salt to the water often acts well. In the elytritis characterized by a free discharge of acid reaction, containing shreds of epithelium and numerous bacteria, the use of an alkaline douche is indicated, and nothing better serves the purpose and brings about the desired result than bicarbonate of

sodium—one level teaspoonful to each quart of water used. Astringents should not be used in these cases. Bichloride of mercury, lysol, creolin, or other antiseptic agents, even in very weak solutions, with the sole exception of weak carbolic acid, should never be employed constantly in the ordinary therapeutic douche. The hot water of the douche greatly increases the power of absorption of the vaginal mucosa, and thus renders the use of these antiseptics dangerous. The action of mercuric bichloride, especially, on the lining epithelium is too well known to require further warning against its use. In mucopurulent catarrhal elytritis, non-gonorrhœal in origin, frequently met with in elderly women and young children, the addition of a tablespoonful of wood vinegar to each quart of water used has been recommended. With this agent I have had no experience in such cases. A weak solution of sulphate of zinc (one half per cent.) has answered every purpose in my hands.

Large hot-water vaginal irrigations should never be employed by a healthy pregnant woman, for the reason that they reduce the bactericidal power of the vaginal secretions. This fact has been thoroughly demonstrated by such investigators as Kronig, Döderlein, and others (*Annals of Gynecology and Pædiatry*, September, 1897).

Reclus, of Paris, asserts that the use of hot enemata in pelvic inflammations is much to be preferred to the vaginal douche. He directs that the water be used at a temperature of from 122° to 131° F., and that after as large a quantity as possible has been very slowly introduced into the rectum, the patient must retain it for at least thirty minutes. On account of the anatomical relations of the parts, the hot water in this way comes into much closer contact with the organs which it is proposed to influence, and is correspondingly more beneficial in its action. He professes to have relieved or cured by this method, possibly combined with dilatation, curettage, and packing of the uterus, many serious cases of perimetrosalpingitis. He says that, if the treatment is correctly persisted in, the infiltration of the cul-de-sac disappears, the peristaltic movements of the intestine break down the adhesions, and, instead of large masses filling up the true pelvis, the exudations and purulent collections are absorbed, the vaginal cul-de-sacs become supple, the uterus is rendered movable, and the region in question resumes almost its normal condition, especially after judicious and moderate applications of massage. Some little practice is necessary to accustom the patient to these enemata, the tendency to tenesmus being difficult to overcome.

I have made use of this method in but a few cases, and not with entirely satisfactory results. The introduction of water at such a high temperature into the rectum produces great discomfort, and I have yet to see the patient that can accustom herself to its use. I am confident that the three-gallon injection, properly ad-

ministered, will, in a majority of cases, bring about equally beneficial results.

381 WEST END AVENUE.

A CASE OF CYSTINURIA ENDING IN RECOVERY.

By JOHN REID, M. A., M. D., C. M.,

BEDHILL, SURREY, ENGLAND.

THE patient, the son of German parents, when seen by me, was about thirty-two years of age, married, and the father of healthy children. He was very obese and worked as a cook; but, nevertheless, his habits were active, and he hunted and worked in his garden. He had drunk wine in moderation, but stated that he had given it up, as it caused more pain in urinating. He had been strong and healthy, without any sickness, prior to the commencement of this disease, over six years before he came to seek my advice, when his family physician treated him for gravel. As, at that time, he did not improve, he consulted a very eminent surgeon, who passed a sound, causing him considerable pain, but obtained no evidence of calculus. He ordered alkalies and sedatives, and the patient said: "I paid two guineas, and the medicines did not do me a bit of good." He also had attacks of muscular rheumatism, which his family physician treated successfully with alkalies. In the summertime he had occasional attacks of diarrhœa, but his motions were otherwise normal and regular.

He complained of great pain in micturition, especially toward the point of the penis; and, on examination, I found a small ulcer in the urethra on the left side and about an eighth of an inch from the meatus urinarius. It was covered with thick pus and appeared to be progressing toward resolution, while it was so tender to the touch as to make me suspect imaginative fear. The urine had a sweet-brier odor, was of about normal color, and was without albumin and sugar, but, on being boiled with liquor potassæ, yielded ammonia. A portion evaporated on a slide showed hexagonal laminae under the microscope, soluble in ammonia water and in liquor potassæ, and reprecipitated by acetic acid in crystals which dissolved in hydrochloric acid. The ammoniacal solution, evaporated, gave the six-sided crystals. On incineration, the characteristic odor of garlic was produced.

Hence I diagnosticated cystinuria, and, accepting the theory that this disease is due to arrested metabolism, I started treatment with quinine, nitric acid, tolu, salicylic acid, and rhubarb in a mixture on November 27th, and on December 17th the urine was improved, but the patient said his dysuria, which for a few days had disappeared, was as bad as ever, and he felt as if he would like to kill some one—a feeling which he often had. I tried, for the urethral ulcer, very weak lead and opium, opium and prussic acid, and lead lotions, but all caused intolerable pain, and the only local treatment which gave relief, was tolerable, and ultimately healed the ulcer, was with calomel. About December 6th I gave gray powder and Dover's powder at bedtime, which was absolutely useless after the first night. On the 16th, iron and strychnine mixture was ordered, and on the 17th, quinine and tannic-acid powders at bedtime.

18th.—Urine normal, and so it continued.

About the 23d he had a fresh attack of pain, and, on examining the urethra, it appeared raw and as if the in-

ternal lining had been removed throughout. He described his condition thus: "I feel, when I make water, as if all through my passage scalding water was being poured." With a mild lead astringent injection, which now caused no inconvenience, he was well in a few days, and in August of the following year he said: "I feel grand now; I wish I had seen you before, so as to save me these years of torture."

Dr. Walter Smith (*British Medical Journal*, April 8, 1898), writing on cystinuria, states that there are only seventy-five cases recorded since the disease was first recognized by Wollaston, ninety years before. He recommends disinfection of the intestine, when he records his two uncured cases. A case is reported in the *Bericht. der Deutsch. chem. Gesellsch.*, Vol. iii, 1891, in which the patient was passing fifteen grains of cystine daily, and in which milk of sulphur seemed to lessen the amount of cystine, but brombenzol and acid derivatives of mercaptan were without influence.

A fermenting organism is said to produce cystine, while it is artificially formed by acting on fibrin with calf's pancreas and salicylic acid for a long time.

Text-books report that cases go on for years without symptoms; but no case of cure has been, to my knowledge, recorded hitherto.

In Watts's *Dictionary of Chemistry*, Vol. ii, 1894, it is stated that cystine has been found in an ox's kidney, and in the liver of a drunkard who died of typhus; that in very small quantities it is a constituent of normal urine. Halliburton, *Chem., Phys., and Path.*, states that cystine is lactic acid in which H is replaced by NH₂ and OH by SH. In normal metabolism, cysteine, a substance akin to cystine, is, according to Delépine, converted into cystine by a torula (p. 769).

Whether the rheumatic attacks in my patient occurred when the cystine became lactic acid or not, I cannot say. I never saw him suffer from them.

Whatever theory of cystinuria may obtain, I think, from the above-reported case, that it is safe to conclude that the disease is curable.*

RADNOR HOUSE.

ACUTE SPINAL ATAXIA (NON-TABETIC), AND ITS RELATION TO OTHER FORMS OF ACUTE ATAXIA.†

By CHARLES L. DANA, M. D.,

NEW YORK.

ACUTE ataxia is a condition in which the patient, in the course of from a few days to one or two weeks, becomes affected with a marked ataxia of the lower, and

sometimes of the upper, extremities. There are with it some other temporary or minor sensory disturbances and some motor weakness, but the ataxia is the dominant and most persistent symptom. Acute ataxia may be classed under the following heads: Acute bulbar and cerebellar ataxia, acute spinal ataxia, and acute peripheral ataxia due to a multiple neuritis of the sensory types. Sometimes ataxia comes on very rapidly in tabes dorsalis.

Historical.—Leyden first described cases of acute ataxia in his work on *Diseases of the Spinal Cord*, Vol. ii, page 203, in the year 1878. Later he described a number of cases having a similar symptomatology, and divided the acute ataxias into the central type and the peripheral type (*Zeitschrift für klinische Medicin*, 1891, p. 576). The central type consists of a group of cases in which the ataxic symptoms come on rather suddenly, and are associated, usually, with cranial-nerve as well as spinal symptoms. These cases were observed usually after acute infectious fevers, such as typhus, small-pox, and so on, and were thought to be due to a disseminated encephalomyelitis. No autopsy was reported.

Later, however, Ebstein (*Deutsches Archiv für klinische Medicin*, x) reported a case with autopsy, death having occurred some time after the first onset of the disease. In this case there were patches of sclerosis, and it was concluded that this, as well as some of the other cases, were early stages of multiple sclerosis.

A number of other observers have reported similar cases, most of them associated with disturbances of speech and other bulbar symptoms.

The peripheral type of acute ataxia includes those cases due to the sensory form of multiple neuritis, the type which is now known as pseudo-tabes.

Pick, in his article on ataxia in the *Real Encyclopädie*, divides acute ataxias into, first, an acute form, with rapid recovery; second, an acute form, with rapid fatal outcome; and, third, a chronic form. These divisions appear to include various types of the central and peripheral ataxias of Leyden. The divisions are rather academical and unimportant.

In Leyden's article on acute ataxia in Nothnagel's *Pathologie*, 1898, the only type described is that in which the lesion is mainly bulbar or pontile, and no reference is made to any distinct form of spinal ataxia. So far as I can learn, therefore, up to recent times, there has been no definite description of an acute ataxia of spinal origin alone not due to tabes.

In 1897, H. Strauss, in the *Charité Annalen*, gave a very careful and detailed account of two cases of acute ataxia with disturbance of the muscular sense and loss of the patellar reflex. Both these cases occurred in men of about the age of thirty-four: neither gave any history of syphilis or of any infection or poison, and the ætiology was obscure. The patients rather rapidly—that is to say, in the course of one or two months—became af-

*The increased pain, of an agonizing character, on applying narcotics, such as opium, etc., in solution to the urethra, is worth noting. It is noteworthy also that in arsenical neuritis, local applications of narcotics, such as opium, aconite, belladonna, chloroform and ether, may increase the pain, and that the inhalation of chloroform gives a still greater increase after the anæsthesia, while, topically, a solution of common salt, chloral, and alcohol relieves, but ammonium chloride in place of sodium chloride is worse than useless.

†Read before the New York Neurological Society, November 6, 1900.

fectured with an ataxia which was very marked, with loss of knee-jerk and of muscular sensation, some motor weakness, a little temporary bladder trouble, no distinct cutaneous anæsthesia, and none of the classical signs of locomotor ataxia, such as the pupillary symptoms or lancinating pains. The cases passed into a somewhat chronic stage, but did not, according to the author, develop tabes. The exact pathology is not given, but the lesion is supposed to be either in the posterior columns or in the peripheral museulosensory neurones. On reading the cases, one is rather forced to the opinion that perhaps, after all, these are instances of tabes dorsalis with acute onset. They, at least, do not come under the category of those cases reported by me. The only case suggestive of or resembling mine is one reported

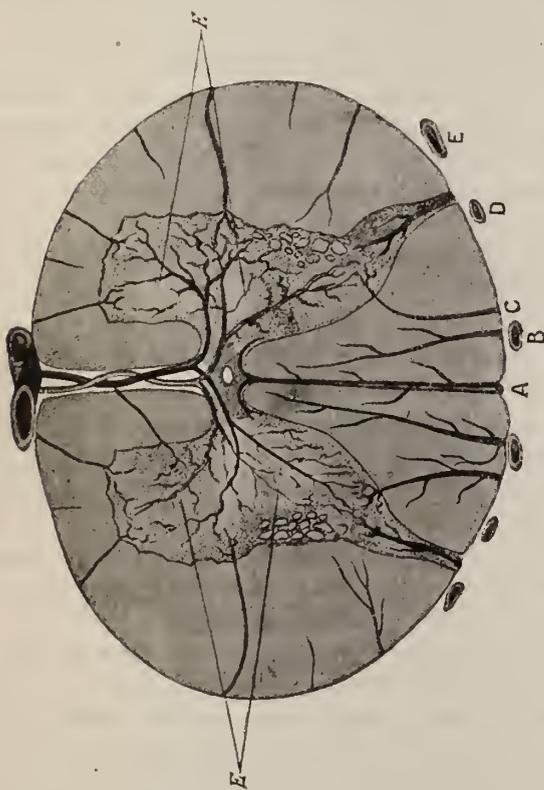

cases, however, were complicated with other symptoms, and resemble only very slightly my own.

Dr. Williamson, in the *Lancet* for August 31, 1895, describes a case of acute ataxic paraplegia occurring in a man fifty years of age. The patient suddenly became paralyzed in the left and then in the right leg. There were pain and aching, retention of urine, and at first no cutaneous anæsthesia; the knee-jerks were present. There was, so far as could be told, some muscular anæsthesia. The patient became completely paralyzed later and died. On post-mortem, a vascular lesion was found including the posterior columns and the posterior part of the lateral columns; in other words, the areas supplied by the two posterolateral anastomoses of the spinal arteries. This case may be, perhaps, considered, a very exaggerated type of the kind I have observed, the lesion being more extensive and severe.

Acute Bulbar Ataxia.—This name may be given to certainly the larger proportion of cases first described by Leyden under the head of the acute central ataxias, although the lesion is not entirely bulbar, and probably to some extent involves the cerebellum and parts of the spinal cord; yet the bulbar symptoms seem to be most prominent, and the implication of this part seems to be the most severe. There can be no question as to the existence of the clinical features characteristic of this ataxia, but it seems to me pretty well settled, also, as stated in the *Historical Review*, that these cases belong to forms of multiple sclerosis.

A patient now under observation illustrates this class of disorders very typically.

F. M., aged twenty-eight, unmarried. His previous history was entirely good, so far as excesses or luetic history was concerned. He had, however, been working very hard and had been subjected, as a clergyman, to the dangers of hospital visitation. In May, 1900, he was attacked with a very active form of suppurative amygdalitis. The tonsils had to be opened and the pus discharged. This attack was followed by evidences of a marked pericarditis, pneumonia, and rheumatic inflammation of some of the joints. He had a very high fever and was delirious during this time. The acute symptoms lasted for over two weeks, during which his life was despaired of. On his becoming convalescent, it was found that he was unable to use his limbs and that his speech was thick and hardly intelligible. He had at one time a little difficulty in deglutition, which soon passed away. He gradually regained some power in the movement of the extremities and his speech became better, but he was entirely unable to coordinate his limbs or use his arms in any purposeful manner. He lay practically helpless in bed for about two months. He then gradually improved and was able to sit up, and he could use his arms a little; he was, however, unable to walk and his speech was thick and syllabic. He was seen by me eight months after the attack. He was then a well-nourished man. His mind was perfectly clear, his speech slow and syllabic. He had a fair degree of strength in both arms and legs, but the movements of these parts were to an extraordinary degree incoordinate and ineffective. There was some tremor of the hands, but in addition to that there were the incoordinate

The arterial supply.—A, the artery of the posterior fissure; B, the interfunicular; C, the posterior horn; D, the posterior root; E, the posterolateral column.

briefly by Gowers in the first volume of his *Text-book*, page 366, that of a married woman, age not given, who had had a syphilitic infection with secondary symptoms the previous year. The ataxia came on suddenly in one day. The knee-jerks were present, although feeble in one leg. There was a slight motor weakness in the left leg, and there was a good deal of hyperæsthesia. The patient was unable to walk for four months, but steadily improved and eventually got well. Gowers refers to this case as one of probably acute parenchymatous myelitis or of acute myelitic ataxia. He refers, also, to certain cases of acute ataxia developing in one limb which he has occasionally seen.

Dr. Campbell Thompson, in the *Lancet* for 1897, Vol. ii, page 1586, gives an account of two cases of ataxia in which one or more limbs were involved. These

movements which prevented him from feeding himself, or dressing himself, or writing, or using his hands for any but the simplest acts, and he was not able to stand without help.

The deep reflexes were marked and he had a slight ankle clonus and some rigidity of the limbs. This rigidity, however, was not at all great and there were no contractures. There was no atrophy or paralysis of any groups of muscles. He had no cutaneous anæsthesia of any kind and suffered no pain. There had been some weakness of the bladder, but this had disappeared, and all his visceral functions were normal. The Babinsky reflex was present in the soles of the feet. He had no nystagmus and no disturbance of any of the cranial nerves, except those connected with speech.

He improved rather rapidly, and was before long able to write and walk a little and use his arms rather effectively. The patient, however, still presents the marked characteristics of ataxia of the four extremities with the scanning speech; but I regard him as a case of multiple sclerosis following an acute infectious disease, presenting the type of bulbar ataxia.

Acute Spinal Ataxia.—The class of acute ataxias to which I particularly wish to call attention is that which I designate "acute spinal ataxia." Although I have no autopsical records to present, the clinical histories are such as to give little doubt as to the nature of the lesion. I feel justified in reporting them, because there has been, so far as I can find, no systematic presentation of this type of disorder. I can best give an idea of its character by reading the history of one of the cases:

CASE I.—J. M. P., aged sixty; family history good; has lived a very active life; has been temperate; had lues twenty years ago, but had no secondary symptoms; has had no fall, or blow, or acute sickness; no excesses of any kind; has of late been under some business strain.

On January 9, 1890, he began to feel some numbness in the feet, and within twenty-four hours this had extended to the mid-dorsal region. He had no pain, fever, or loss of power in the limbs; the bladder and rectum were normal, except that the bladder was less sensitive and there was a tendency to retention. The symptoms gradually got worse. He was affected with a tight-band sensation around the waist and had a feeling of pressure on the chest. These sensations were worse at night and he could not sleep. He still had no distinct paraplegia, but he could not walk very well.

January 19th.—He is able to walk, but not well; he has a staggering, ataxic gait and suffers from general weakness, and soon tires. He cannot stand with the eyes closed. There is no marked loss of power in the arms or legs, as tested by passive and active movements. No atrophy. There is a slight degree of tactile anæsthesia in the lower limbs; no thermo-anæsthesia and no analgesia. There is no loss of sense of position; he can place the toe upon the knee of the opposite leg with the eyes closed. There is distinct static ataxia and ataxia upon walking. The arms are practically normal, though there is a slight ataxic tremor in the right arm. He cannot write quite so well as before. There is no trouble with the bladder or rectal functions. The knee-jerks are slightly exaggerated. The pupils are normal and react to light and accommodation. Optic nerve normal; mind is clear; other bodily functions are normal.

The case presented the history of a very acute ataxia, with slight loss of power in the lower limbs, without any pains. My diagnosis at the time was one of acute softening or hæmorrhage, involving mainly the posterior columns. The patient was confined to bed most of the time for several weeks. He then gradually improved, and finally recovered.

CASE II.—C. H. A., aged sixty-six, married; is a man of somewhat corpulent habit, but vigorous constitution. His previous habits have been good; there have been no excesses in alcohol or tobacco and no specific history. He had been a very hard-working man, having great business responsibilities. He was seen by me in November, and I learned that during each previous summer he had had an attack of numbness in the right leg and right arm, and since then had had these temporary attacks on both sides, but they had completely passed away, and he had been pretty well during the latter part of the summer and fall. Previous to my seeing him he had exposed himself to wet and cold while out fishing. On November 24th, while going down-stairs, he noticed a numbness and weakness in the legs, but was able to walk, and took a train to a neighboring health resort. Within twenty-four hours his legs were so weak that he could not walk; they were also very numb. He had no pain, no bladder trouble, but his bowels were constipated. Three days after his attack he was seen by myself in consultation with Dr. William Wood, and could then walk a little if supported, but his gait was very ataxic and he could not stand alone with the eyes closed. While lying down he could move the limbs in all directions, but could not extend the toes or move the feet laterally without great effort. He had a slight degree of tactile anæsthesia in the feet, but no pain or temperature anæsthesia. There was very decided loss of muscular sense, as shown by his inability to locate his limbs placed in different positions, or to put them at a given spot. There was a considerable degree of motor weakness also in the lower limbs, but nothing more than what would be termed a partial paralysis. The arms showed some weakness also. Dynamometer; left, 20, normal being about 50. There was no anæsthesia in the arms of any kind, but a loss of muscle sense, as tested by weight. The plantar reflexes were present, the cremasteric absent; knee-jerks absent even to reinforcement. There was no atrophy or atrophic disturbance; the muscles responded well to the faradic current; muscular sensibility was good; vision was normal for his age; the pupils responded to light and accommodation; the optic nerve was normal; the hearing was good; there were slight incontinence of urine and some constipation; there was no disease of the heart, lungs, or kidneys.

CASE III.—Mr. E., aged seventy-six, American, a business man. His family history is unimportant, except that he had one daughter who suffered from melancholia. He had lues at the age of twenty and was treated for it, and apparently got entirely well. He was an active, vigorous man, living a temperate and regular life, so far as was known. At the age of seventy he walked and got around like a man of fifty. One year ago, when he was seventy-five, he was again infected with lues and was treated for it, suffering from secondary symptoms, including iritis, which occurred about six months after the infection. Seen by me in January, 1900, in consultation with Dr. Sinclair. The history given to me was that he had been feeling perfectly well

and had had no pains of any kind. One week ago he felt some numbness in the feet, but no pain; this increased, and with it there was some weakness of the legs, so that in four days he had to go to bed, and on the sixth day he could not walk or stand unsupported, and he had some trouble in controlling the sphincters of the bladder and rectum. He suffered no pain during this time.

He was a well-nourished man of spare habit; speech somewhat thick and memory sometimes at fault, but, on the whole, clear-headed and sensible. He could move the legs in all directions and move the feet, but there was considerable loss of power, though by no means a paraplegia; the legs were about equally affected; he could stand with some support. There was no rigidity or spasm; the knee-jerks were normal or a little exaggerated; no Achilles reflex; plantar reflex and epigastric reflex slight; no atrophy. He had a slight tactile anaesthesia up to the line of the groin and the fold of the buttocks, but none of the scrotum; no pain or temperature anaesthesia; some loss of deep sensibility. He did not know the position of the limbs—placed them awkwardly at different points; did not know when they were crossed. When sitting and asked to cross the legs, he could not tell which one he would cross. On striking one of the patellar tendons, there was at times a reflex jerk of the tendon of the opposite side—crossed patellar reflex. The arms were normal in every way, there being no paralysis or ataxia or anaesthesia; there was no sweating, reddening, or atrophic disturbance; the pupils were normal, except that the right iris had been injured by inflammation. He had a characteristic copper-colored eruption all over the trunk and legs. Under antisypilitic treatment he improved rapidly, and in two months was able to walk alone. Sensation returned to a marked extent and there was no evidence of any development of the symptoms of locomotor ataxia.

CASE IV.—Mr. D. G., aged thirty-eight, married, a lawyer by profession. Family and personal history good. Habits good. At the age of twenty he had a specific infection, followed by secondary symptoms, for which he was thoroughly treated. At the age of twenty-five he had some headaches and a slight aphasia lasting only a day. At the age of thirty he had, without any special warning, an attack of acute ataxia in the left arm. This came on in the morning with a feeling of numbness as though he had slept on it. There was a slight degree of tactile anaesthesia at the time, but the ataxia was the marked symptom, so that he was not able to use his hand in writing or buttoning his clothes, and he lost the sense of position. The arm was not paralyzed at this time. This acute ataxia lasted for several months, but steadily improved, and finally practically disappeared. Seven years later, when he was thirty-seven years of age, he had, rather suddenly, an attack of paraplegia, which was nearly complete, and accompanied with a good deal of numbness and paraesthesia, but with no anaesthesia at the time. From this also he gradually recovered, and is at the present time practically well, though he has slight ataxia still in the left arm. The two most marked incidents in his case have been, therefore, the acute ataxia in the arm and the later paraplegia of the legs.

Ætiology of the Affection.—I cannot attempt to draw any broad conclusions from the small clinical experience which I have had, and I have been unable to find any cases exactly like it in literature. Adamkiewicz

has reported cases of spinal-cord disease due to lesions of the vessels somewhat suggestive of my own, but the lesions were by no means confined to the posterior columns. The same is true of cases reported by Williamson in his monograph, *Disease of the Nervous System Dependent upon Vascular Supply*.

The provisional conclusion which I should draw aetiologically is that the cases are due to senile arterial changes or to syphilitic lesion of the posterior blood-vessels of the spinal cord, causing either a blocking up, or hæmorrhage, or both, with the usual reactive process. It seems to be a characteristic of the luetic virus in its exudative stage to affect especially the lateral and anterior portions of the cord, producing the well-known type of syphilitic spinal paralysis.

It is the tendency of the disease in its degenerative stage to affect the peripheral sensory neurones, but it seems that in old age the exudative and vascular conditions caused by syphilis may also attack the posterior areas of the cord alone.

Symptoms.—In all my cases the ataxia was especially marked. The patients did not know the position of their limbs and could not stand or walk except in the characteristic ataxic manner. On the other hand, cutaneous sensations were not markedly involved in any cases. There was always some tactile anaesthesia, but no marked loss of pain or thermic sense. The knee-jerks were abolished in two cases, but not in the third, in which case they were slightly exaggerated. There was some loss of motor strength, but the patient could always move the limbs freely in every direction and could stand with help. There was loss of cutaneous reflexes. The Babinski phenomenon was not tested for. There was no special wasting of the limbs or change in electrical reaction. There was weakness of the bladder, with some constipation, but these functions were not entirely in abeyance. The patient suffered no pain, either at the time of onset or later. There were no lightning pains, no crampings or jerking, no girdle pains, though there were some girdle sensations. The vascular and glandular functions of the limbs were not especially disturbed. There was in no cases any lesion of the cranial nerves, nor were the arms affected, except in one case, in which there was some paræsthesia of the fingers for a time.

Course and Prognosis.—In all my cases the patients rather rapidly improved. One of them is practically well, eight years since his attack. Another is nearly well, six months since his attack. Another got very much better, but succumbed two years later to what was apparently cerebral thrombosis. Gowers's patient recovered. The prognosis may be said to be better than that of the ordinary type of syphilitic spinal paralysis, or transverse myelitis.

Diagnosis.—The disease is so characteristic that it can hardly be mistaken for any other malady. In young patients such a sudden onset might be produced by mul-

multiple sclerosis or multiple neuritis. I cannot deny the possibility of such an affection occurring in youth, but, if so, I should see no reason why it should not run the same course as in the older-age cases.

Locomotor ataxia never comes on with any such acute onset as in the cases which I am describing. In acute bulbar ataxia there are always some symptoms involving the cranial nerves, and the arms as well as the legs are affected.

Pathology.—It is perhaps unfortunate that I cannot complete my records by the presentation of a pathological demonstration, but the age of the patients, the acute onset, the history of syphilis, the characteristic symptoms, all make it practically certain that it is a vascular disorder involving either hæmorrhage or softening. The absence of pain or fever and the rapid recovery show that the process is not an inflammatory or a progressive and degenerative one.

The case reported by Williamson (*Lancet*, 1894) shows very conclusively what we should *a priori* expect to be true, namely, that there may be thrombotic softening of certain parts of the spinal cord by thickening of the blood-vessels through syphilitic endarteritis or other cause. It has been shown by Kadyi and Adamkiewicz, Williamson, and others that the posterior columns of the spinal cord and the posterior part of the lateral columns receive a blood supply from the two posterolateral plexuses that run on the posterior surface of the spinal cord. These send arteries into the posterior column, the posterior root, the posterior horn, the intra-funicular fissure, and the posterior median fissure. It is perfectly conceivable that a lesion like a gummatous inflammation or the pressure of an inflammatory process from any cause might produce a blocking of one or more of these vessels, or that they might be stopped up by emboli from septic sources. The pathology of combined sclerosis shows that this is the case. In two patients of my own upon whom an autopsy was made, and who were suffering from combined sclerosis, there occurred finally a softening of the posterior part of the spinal cord, following closely the area supplied by these plexuses. In Williamson's case, above referred to, the same lesion was observed, and this author has called attention to the fact that in hereditary ataxia the early lesion, at least, follows more or less closely the vascular supply furnished by these vessels. There is little doubt in my mind that in the cases of acute ataxia which I described there was a sudden thrombotic softening produced by an involvement of these vascular areas.

Summary.—Acute ataxia occurs occasionally in tabes dorsalis, but is associated usually with characteristic symptoms.

Acute non-tabetic spinal ataxia occurs as a manifestation of spinal syphilis or senile arterial changes, and shows itself by a sudden onset of temporary motor weakness and bladder troubles, great ataxia, and minor sensory disorders. It may affect only one extremity, but

usually affects the lower limbs. The tendency is to nearly complete recovery.

Acute bulbar or bulbo-cerebellar ataxia occurs as a sequel of some acute infection, and is usually the beginning of a form of multiple sclerosis.

Acute neuritic ataxia occurs as the result of multiple neuritis of the sensory type. It is seen usually in the non-alcoholic forms of neuritis, especially those due to metallic poisons, like arsenic, or to diphtheria.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Concluded from page 635.)

Treatment.—Among the causes of the death of a fœtus *in utero* not already enumerated may be mentioned hydrocephalus and malformations of the child, rupture of the uterus, deformities of the pelvis, and ovarian and fibroid tumors. These complications may so seriously interfere with normal labor as to render it absolutely impossible for a child to be born unless artificial means are adopted. These conditions, however, are so fully set forth in the various text-books of obstetrics that I refer my readers to them for further information.

It is not my purpose to enter fully into the methods of treatment of the many pathological conditions that produce the death of a fœtus. From what has been stated, it will be seen that the causes leading up to and producing the death and expulsion of a fœtus are exceedingly numerous and complicated. Disease has no creed or conscience, and it feels no sympathy or remorse. Occasionally it stalks forth in cold, haughty mien, gloating with leering jest over any agonies that it can inflict. More frequently it prefers the wily ways of insidious intent, and with quiet and stealthy tread it lurks about concealed from view, yet with subtle craft and cunning weaving devices and contrivances for the opportune moment. Between these extremes there are all manner of methods of attack upon a fœtus. They may come singly or in combination, innocently or maliciously. In what way soever they arrive, they prove an alarmingly serious menace to the welfare of the almost defenseless fœtus. Thus it is apparent that the treatment will vary according to the nature and intent of the particular attack. It would be obviously impossible to enter fully into a treatise on the treatment of so many different conditions and complications. I shall content myself with an outline of some of the salient principles only. These will be broad, general statements on some of the most frequent causes of this unfortunate condition. When a woman has lost the product of conception before the natural term of gestation, a very careful scrutiny should immediately be instituted. One of the first principles here involved should be to ascertain ac-

curately the history of the mother. This should include that of her parents as well. In this way any constitutional or congenital defect can usually be elicited. When this matter is cleared up, the menstrual history should be noted, and any peculiarities or anomalies carefully remarked. The question of falls, blows, jerks, or accidents of any sort, should be answered. Ascertain if the mother has recently changed from one climate to another. These and other questions which the peculiarities of the case may suggest will often throw a flood of light upon the case. It occasionally happens, however, that no unusual history of sufficient importance to account for reiterated miscarriages will be forthcoming. Under such circumstances the male parent should be examined, his previous illnesses, acquired or congenital defects, elicited, and, finally, his semen microscopically examined. If either parent has had syphilis it is impossible to determine when its lethal influence has entirely passed away; the fact that they give the history of a lengthened term of treatment should have no effect upon the judgment of the physician. It is quite probable that the majority of men and women who have contracted syphilis neglect to carry the treatment to the extent of entire elimination of the disease. This is due to carelessness, and not to the fact that the disease cannot be absolutely eradicated. When, therefore, either parent has been afflicted with syphilis, that one should at once be placed upon antisiphilitic treatment. If the disease is of recent origin, mercurial treatment is much more satisfactory than the iodide of potassium. On the contrary, when in the tertiary stage, the latter drug will be found to be the more beneficial. The physician should not be content with small doses. The tolerance of such people to the effects of the drug is remarkable. Beginning with ten grains three or four times a day, it should be gradually increased according to the effects produced, until twenty, thirty, or forty grains are taken at one dose. Sometimes it will be found that mercury or iodide of potassium, when given singly, does not answer so well as in combination. The treatment should be continued for many months, or until the physician is satisfied that none of the virus remains. Besides its beneficial effects upon syphilis, mercury is an excellent alterative, and frequently has acknowledged influence in hypertrophy of the uterus and in certain varieties of endometritis.

The treatment of pregnant women during an attack of pneumonia, typhoid fever, or any of the zymotic diseases, is full of great care and responsibility. If possible, the temperature should be maintained below 104° F. by antipyretics and other suitable treatment, for it has been demonstrated that the danger to the fœtus in diseases associated with elevation of temperature depends almost entirely upon the degree of heat that is attained.

Any constitutional peculiarity, such as a strumous, rheumatic, or gouty diathesis, should be treated by appropriate remedies. A constitutional condition that fre-

quently predisposes to abortion is anæmia. The subjects of this complaint should be carefully guided back into good health by tonics of iron and other remedies, plenty of fresh air, massage, sea bathing, and suitable exercise.

The local conditions of the uterus and its appendages are to be ascertained, and treatment adopted in accordance with the requirements of any deviation that may be found present. Tight lacing and chronic constipation are frequent causes of catarrhal conditions of the uterus, and should be remedied by measures best calculated to the needs of such cases. One of the most frequent local conditions that seriously interferes with the progress of pregnancy is endometritis. This disease is much more frequent than is usually believed. An inflammation of the mucous membranes of the uterus may be brought about by either local or remote causes, and, in estimating the proper method of restoring the endometrium to a physiological condition, the remote causes should constantly be borne in mind. Valvular disease of the heart, cirrhosis of the liver, albuminuria, passive congestion of the portal circulation, obesity, tight lacing, constipation, each and all present their quota in accounting for the far-back commencement of a congested uterus. Local treatment for such causes is manifestly of little benefit and affords but temporary relief. I have long maintained that the reckless and indiscriminate use of the curette in the wholesale treatment of certain uterine ailments is positively unscientific and dangerous. In properly selected cases, this method is frequently followed by brilliant results, but it cannot be expected that all local pathological diseases of the uterus will yield to any one operative procedure. It is difficult sometimes to properly estimate how far the cause depends upon constitutional defects and how far it is attributable to local causes only. It is a wise precaution, so far as possible, to put the various emunctories of the body in a satisfactory condition before attempting to rectify the local defects. It should be constantly borne in mind that curettage of the uterus is an operation extremely difficult to perform properly, and that it is often attended by unforeseen dangers. When there are no complications present, it is usually a simple procedure and should not result in untoward symptoms. Difficulties arise when there have been antecedent inflammatory attacks in the tubes or ovaries. Frequently then the uterus is bound down by inflammatory adhesions, and the surgeon, in order to bring the uterus down sufficiently far into a proper field for inspection, is apt to tear away adhesions and bring about an acute attack of pelvic peritonitis. When fœtal products have remained in the cavity of the uterus for some time, its walls are so soft and friable that a sharp curette is liable to penetrate into the peritoneal cavity unless the surgeon is on his guard. It is, therefore, not wise to look upon this operation as one free from risks, for frequently disastrous results follow in the wake of indiscriminate recklessness. It is probably a more dangerous operation to undertake than is an

uncomplicated ovariectomy. A serious condition obtains when the uterus is in a perfectly healthy state and the fœtus has gone to the full term of gestation and yet delivery cannot take place for mechanical reasons. The causes, then, are usually a contracted pelvis or obstruction due to a tumor being jammed down in the pelvis. There is then such a disproportion between the natural passages and the size of the fœtus that it becomes impossible for a viable child to be delivered except by artificial means. Such a complication is one peculiarly hazardous to the child and places the medical attendant in a tremendously responsible situation, for the life of both mother and child are then in imminent jeopardy. It is at the same time a position that calls for the most evenly balanced judgment that it is possible to imagine.

In attempting to discuss this complication here, I shall endeavor to approach the subject free from the thralldom of preconceived ideas and unbiased in the advocacy of any one method of surgical procedure beyond its merits. When the deformity of the pelvis of the mother, or some unnatural development on the part of the fœtus, is so pronounced as to render delivery impossible, the cunning hand of the surgeon may then be of the utmost importance to life. It is highly commendatory to the standing of the medical profession that the principles now advocated have been so beneficial to mankind. The methods in vogue, not many years ago, of resorting to the operation of craniotomy, with all the appalling disasters that follow in its wake, are, happily, now much less frequent. Craniotomy forms one of the darkest pages in the history of obstetrics. When one contemplates the frequency with which this operation was resorted to in the past, in preference to others much less dangerous, it would seem that the spirit of scientific midwifery was long lulled to sleep and that Nature had become emasculated. The operation of eviscerating the yet warm and quivering body of an innocent babe from its mother's womb should be reserved for very rare and exceptional cases, such as hydrocephalus, or when the child is already dead. Much more satisfactory and humane methods are the Cæsarean section or Porro's operation. Unlike the majority of recent triumphs in surgery, Porro's operation is not one that has been accepted after having been performed and described many years before, but is of comparatively recent origin. The first successful case upon record was performed in the year 1876 by Porro, of Batavia. It has since been performed both in Europe and in this country with comparatively good results. Heretofore, and even at the present time, this operation and Cæsarean section have been indiscriminately advocated when the complications present called for one or the other method. I believe this to be a mistake. Whether the classical section can have any advantages over its recent rival rests entirely upon a question of morals. It is probable that each of these operations has its peculiar indications. Certain it is that there are well-defined conditions and complications present in

pregnancy when Porro's method would seem to be the only scientific course to adopt. Each method may possess well-defined advantages over the other, and, in estimating the relative values of these two operations a number of important conditions should be remembered. In all cases where pregnancy has advanced to the full term and labor is complicated by the presence of a fibroid tumor in the substance of the uterus, hysterectomy is the preferable operation. There are exceptional cases when the tumor is small and of the nodular variety; it may then be possible to enucleate the growth when performing the Cæsarean section. In those instances in which there is contraction of the pelvis, or obstruction due to other causes, and where labor has proceeded for a long time and the uterus has become putrid, Porro's operation ought to be the one selected. In certain operations begun as Cæsarean section, but which become complicated by difficulties in the detachment of the placenta, uncontrollable hæmorrhages or atresia of the vagina, Porro's is the preferable operation. These are some of the advantages that this operation possesses over the Cæsarean section. The objection that has been raised against this operation is that the woman forever afterward remains sterile. When a case is encountered where a woman has a deformed pelvis and a contraction of its diameters, so that one or other of these two operations is called for, and granted that one method will save her life equally certainly with the other, the one that would place her in such a condition that pregnancy could not again occur, it would seem, ought to be the preferable operation. I look upon this point alone as a decided advantage for Porro's method. Such a procedure leaves the life of the woman absolutely free, so far as any future dangers of this kind are concerned.

There is no reason why either of these operations, when properly planned and the details carried out with as much care and precaution as in other abdominal sections, should not be almost entirely free from risk, so far as the lives of the mother and child are concerned. It is to be greatly regretted that in the majority of instances the idea of an operation does not enter into the mind of the attending physician until the patient has become almost entirely exhausted from the reiterated efforts of the uterus to expel the fœtus. An operation of this character, above all others, should be done opportunely, and not left until rough manipulations have exhausted the strength of the woman and materially reduced the chances for success. It can readily be understood why the mortality of these operations has remained so high, in view of the fact that it is usually done as a forlorn hope. An operation that has recently sprung into prominence, and one that has received considerable attention, is symphysiotomy. This method of delivery is not of recent origin, but is one that was advocated and described by a French medical student so far back as the year 1768. At first his method was received with incredulity, but subsequently having performed the operation success-

fully upon a woman who had previously given birth to four dead children, his operation was at once adopted and he became the recipient of much adulation and esteem. He was looked upon as a benefactor of mankind, and the neglected student became in the eyes of the nation an illustrious personage. Shortly afterward, however, the operation lapsed into neglect, until recently revived. The conditions calling for this method of operation are exceedingly limited. It is only in slightly contracted pelvis that any benefit can be effected. In well-marked deformities, this operation gives way to one or other of the abdominal methods, and probably should only be performed in cases where the question of premature labor may be entertained. According to the most recent accounts, it is an operation frequently beset with difficulties and positive dangers. Septicæmia, hæmorrhages, ossification of the symphysis, laceration of the bladder, and prolapse of the vagina have followed as a result.

Some time ago a very interesting case of complicated pregnancy was presented to me for an opinion. The patient was under the care of Dr. E. J. Rothwell, of Denver. She was thirty-two years of age, of good general health, and had been married for several years. A few years previously she was delivered of twins weighing three pounds and a half each. Afterward she became pregnant again, but it was found quite impossible to deliver the child on account of a contracted pelvis, and craniotomy was done. She was confined to her bed for four months afterward as a result of septicæmia. Again she became pregnant, and was within two weeks of the period of her expected confinement when I was called in to see her. On making an examination, several interesting conditions became manifest. I could determine that the child was alive and situated higher up than normally, and in the left occipito-posterior position. The abdomen was enormously distended. *Per vaginam* it was quite impossible to reach the cervix. I could not at first account for the high situation of the child. The outline of the lower part of the abdomen appeared somewhat uneven, and, by further and more careful examination, I had a suspicion that there was an ovarian cyst jammed down in the pelvis. It was difficult, however, to give a positive opinion on account of the unusual degree of distention: All the diameters of the pelvis were contracted, and it was utterly impossible for the woman to be delivered by the normal route. The necessary preparations were made for a Porro's or Cæsarean section. Chloroform was given and an incision made down the median line from a point above the umbilicus to the pubes. When the peritonæum was cut through, the uterus bulged forward into the opening. A rubber ligature was passed round the uterus close to the cervix and tied tightly. An incision was then made into the substance of the uterus, beginning at the fundus and going straight down the full length of the uterus. The membranes were soon reached and the child extracted. Be-

fore this last step was undertaken flat sponges were packed well around the uterus and over the intestines. This precaution was taken to prevent any liquor amnii from dribbling into the peritoneal cavity. When the child was removed the reasons for its high position became apparent and the suspicion of a tumor was confirmed. There was a large cystic tumor, evidently of the left ovary, packed down in Douglas's sac, and a second one from the right ovary. When I saw the nature of the complication and the fact that the pelvis was much contracted, I concluded to remove the uterus with the tumors. What made the whole situation more unique was the fact that the tumors were both dermoids. They contained broken-down sebaceous matter, hair, skin, and teeth. The case was a very satisfactory one in every respect. Both the child and mother recovered, and are to-day alive and well.

I have now reached the end of my task, however incompletely it may have been accomplished. To me it has been a pleasant recreation, and I have had the sensation of one tramping through an unexplored forest. A rich harvest remains to be garnered, although yet so unfruitful.

12 WEST FORTIETH STREET.

GRIPPE, PNEUMONIA, AND INSANITY.

BY EMILE ARONSON, M. D.,

DALLAS, TEXAS.

IN a very interesting article published in a recent number of the *Journal of the American Medical Association* Dr. H. S. Anders spoke on some clinical features of epidemic influenza observed by him. Out of 128 cases, he found only one which manifested extreme mental disorder in the shape of an acute maniacal delirium lasting about three weeks. Melancholic depressions as a sequel of influenza have been frequently observed, yet the case which I hereby report has shown so many peculiar phenomena that I have thought it worth publishing:

Miss E. R. has always been well; the family history shows nothing abnormal, only that the mother died of carcinoma of the uterus. The patient has always been of pleasant and cheerful disposition. During the epidemic of influenza her brother and sister had just recovered without any unusual complications or after-effects, when, on January 14th, I was called to see this patient. I found her in bed with all the manifestations of influenza, *i. e.*, sore throat, headache, and back-ache, extremely nauseated, the tongue heavily coated, the temperature 102° F., the pulse 90. By the 16th all the symptoms had left except the nausea, which, under the use of bismuth, lime water, etc., also passed away. All in all, I considered it a mild attack of the grippe, yet the patient was very much worried about her condition and requested me to call twice daily. On the 18th she felt strong enough to leave her bed and go to a dance, from which she returned complaining of a severe chill and intense pain in the right side of her chest. On the 19th or 20th a sanguinolent sputum appeared, the pain and cough were distress-

ing, the nausea returned, and the temperature ran up to 103° and 104° F. The patient complained of intense headache and became slightly delirious; there was a constant interlocking and unlocking of the fingers, and the wrists were kept frequently in dorsal flexion; the tongue was thick, pasty, and heavily coated; a slight nosebleed was also observed. Under the idea of a meningeal complication, another physician was called in, who, while fully agreeing with me in the diagnosis of grippe-pneumonia and cerebral involvement, and endorsing my treatment, thought of the possibility of malaria. On the 21st the patient was a raving maniac, screaming and yelling, trying to tear her clothes off and to leave her bed. The sputum was clear and the temperature went down to 100° F. On the 22d she was quiet, lying with closed eyes, which even considerable force could not open. She did not respond to questions, did not talk, and did not ask for anything. The muscles of the neck were rigid, and the jaws tightly locked; the abdomen was flat, yet even a slight touch on the abdomen caused an expression of pain on her face; in fact, this hyperæsthesia of the skin of the abdomen was the only thing that called forth any manifestation of consciousness or sensibility. She passed urine and stools involuntarily. She would take no food or medicine by the mouth, and I had to resort to cleansing and nutrient enemata. On the 23d the temperature was 100° F. (9 A. M.), 102° F. (3 P. M.), and 100° F. (6 P. M.); she slept well and was only partly delirious. On the 24th she took some nourishment in the shape of milk, beef-tea, and grape-juice. In the afternoon she became restless again; there was constant rambling talk, and she sought to leave the bed, insisting that she was dead, that her body and her spine were twisted, and that she had done something wrong.

The alarmed family urged another consultation, to which I agreed. After a most careful and close examination, the consulting physician was inclined to consider the case one of the abnormal forms of typhoid fever, which diagnosis was accepted by me with some reservation, since many symptoms of typhoid were missing, yet pronounced symptoms of meningitis, such as Kernig's sign, etc., were also missing. For the next thirty-six hours his diagnosis seemed to be correct, considerable meteorism appearing and enemata bringing away several stools of the color of typhoid fever stools. On this day (the 24th) the temperature was 100° F. (8 A. M.), 102° F. (9.30 A. M.), 102° F. (12.30 P. M.), 101° F. (4 P. M.), 103° F. (7.30 P. M.), and 102° F. (1 A. M., 25th). During the 25th she did not sleep, but lay with the eyes quite open. She seemed to understand what was said to her, but did not answer, except with some inarticulate sound, yet took medicine and nourishment.

On the 25th the temperature was 102° F. (8 A. M.), 101° F. (noon), 101° F. (4 P. M.), 101° F. (8 P. M.), 101° F. (1.30 A. M., 26th).

On the 26th the temperature was 103° F. (8 A. M.), 101° F. (noon), 101° F. (4 P. M.), 100° F. (8 P. M.), and 102° F. (midnight).

On the 27th the temperature was 100° F. (8 A. M.), 100° F. (noon), 101° F. (8 P. M.), and 100° F. (midnight). She took some peptonized milk, had her nutrient enema, and slept the whole day. At midnight she expelled a large amount of gas and lay in a deep stupor, the extremities cold. She did not swallow.

On the 28th the temperature was 99° F. (8 A. M.), 99° F. (noon), 100° F. (4 P. M.), 100° F. (8 P. M.), 100° F. (midnight).

On the 29th the temperature was 100° F. (9 A. M.),

100° F. (noon), 100° F. (4 P. M.), 99° F. (8 P. M.), 99° F. (midnight).

From the 30th of January to February 5th the temperature ranged from 99° F. to 98° F. every day.

The entries made by two competent day and night nurses show, then, that only on the 25th and 26th the temperature was above 102° F., with the exception of the temperature on the 19th and 20th, when the pneumonia appeared. The entries show, further, that the morning temperatures were always higher than those of the evening; the temperature was always taken by the rectum, and the thermometer was left five minutes *in situ*.

The pulse was good all along and ran in typical relation to the temperature, only once mounting to 112, on the night of the 26th, and being mostly between 80 and 90 and of good volume.

The periods of stupor and coma became shorter, she began to gain in strength, and she was soon able to sit up and take sufficient food by the mouth. Yet almost two months from the beginning of her sickness she did not show any interest in her surroundings, was apathetic, did not believe that she would get well, complained of being overfed, wished to kill herself, and, with this thought of self-destruction in her mind, managed repeatedly to escape the watchfulness of her attendants, and was found one cold morning barefooted on the back porch of the house, another time hiding herself under the house. She was otherwise docile and gentle, took her medicines willingly, and took outdoor exercise every day.

The recovery has been a very slow one, yet the prognosis seems to be favorable, and I believe that in the course of time she will regain her normal mental and physical health. The treatment of the case had to be adapted to the indications arising. Her diet was naturally a liquid one, consisting of peptonized milk, beef-tea, and grape-juice; brandy was given only when absolutely necessary. Nutrient enemata were given first at six-hour intervals, and, seeing that they were absorbed, at shorter intervals; the addition of a few drops of tincture of opium to the nutrient enemata seemed to help considerably. A cleansing enema of a simple solution of salt in water (warm) was given every day. To allay the intense excitement, morphine, bromides, and hyoscine had to be used. Chloretone, in ten-grain doses, procured sleep more promptly than trional in twelve- to eighteen-grain doses. Full baths, sponging, and ice-bags to the forehead and neck were used according to the conditions arising.

NOTES ON THE TREATMENT OF DIPHTHERIA, BASED ON THE METHODS OF THE NEW YORK CITY HOSPITALS.

By WILLIAM L. SOMERSET, M. D.

NEW YORK.

ABOUT ten years ago, the chief characteristic of the treatment to which diphtheria patients were subjected was activity. As regards the doctor, his fertility of resource was certainly admirable, even though his judgment might occasionally be condemned. As regards the patient, the life was strenuous, to a degree equaled only by that of the nurse. The treatment was then, as now, specific and symptomatic; local and constitutional. There were irrigations, fumigations, or, better, inhalations, swabs and sprays, local and systemic specifics, al-

teratives and resolvents. Emesis, stimulation, purgation, or depletion, all played their part, and continue to do so—with a much more rational appreciation of when and why they are indicated, however. Far be it from me to refer to the treatment of that time with anything but respect. Some of it was ill-advised and overdone, and, perhaps, injurious; some of it was certainly ineffectual; but it was all indicative of anxiety to relieve, and out of it has been culled a system of treatment that, judiciously coupled with the last great specific, antitoxine, answers every practical and theoretical requirement and takes every possible advantage of this most treacherous disease. It may be of interest and advantage to indicate, briefly, the lines along which the existing methods of treatment were evolved.

The idea has prevailed for at least fifty years that there was, or, in any case, ought to be, some means of exerting an influence on the human body whereby the further formation of pseudomembrane would be stopped and that already formed would be hastily got rid of. Inasmuch as the disease—fifty years ago—was considered to be a strictly local one (except in malignant cases, where some influence poisonous to the system was recognized), the specifics of those days were for local effect only. The bromide, chlorate, and sulphide of potassium, bromine, glycerin, the alkalies, all received limited recognition. Emetics were freely used, but they were not considered to have any effect on the *peculiar nature* of the inflammation. By far the most popular remedy advocated by Bretonneau himself was mercury. If the system was brought under the mercurial influence, then would the “peculiar nature” of the inflammatory process be modified. The character of the secretion would be changed from “plastic to mucous, or to puruloid and diffuent.” The further production of false membrane would be prevented. The separation of that already formed would be favored, also possibly its solution and absorption. Mercury came to stay, and until it was driven from the field by antitoxine there were many who insisted on its use in the form of bichloride by hypodermic injection, the argument still being that it caused the absorption of fibrinous exudate. Mercury did not have the field to itself. Tincture of the chloride of iron was used with frequency and freedom. The stock solution was one third iron and two thirds glycerin. The dose was a teaspoonful every hour, or even every half hour. Fever was not a contraindication to the use of this mixture. If the nausea produced was excessive, the local effect was sacrificed and the mixture was diluted with vichy. The iron frequently was discontinued on account of its ill effects. The same was true of mercury. Alcohol, in the form of whiskey or brandy, was relegated to its proper place as a stimulant early in the nineties, having lost prestige as a specific. Potassium chlorate, at about the same time, fell into general and richly merited disrepute. As a matter of fact, the evidence in favor of any of the specifics, prior to anti-

toxine, was very incomplete and unsatisfactory. In 1895 the use of antitoxine became general. There was, of necessity, considerable difference of opinion about the dose. From twenty-five hundred to four thousand units are, I think, the most generally accepted limits at the present time. I have no sympathy with such use of antitoxine as is recommended to us from Boston, viz., twenty thousand units daily for three or four successive days. With the introduction of antitoxine, other specifics dropped out of use, I trust, permanently.

That something ought to be done locally for a diphtheritic throat has long been firmly believed, and many methods have been resorted to. Applying the sulphate of zinc or of aluminum or the nitrate of silver, in solution; or dusting with astringent powders, was in vogue as long ago as fifty years. Bretonneau believed in dusting the membrane with calomel. Sprays and irrigation solutions came later. Local applications, during the last ten years, have been used to dissolve the membrane, to disinfect the infected area, to lessen the inflammation, or to cleanse the throat—thus diminishing the absorption of toxins and products of putrefaction and contributing to the comfort of the patient.

The attempt to dissolve or digest diphtheritic pseudomembrane *in situ* has, I think, been abandoned. To render the pharyngeal and nasal mucous membrane of a diphtheritic patient free from Klebs-Loeffler bacilli by means of germicidal solutions has been proved to be impossible. The surface of a mucous membrane to which an antiseptic solution has been applied may be made sterile for two hours—no longer. Furthermore, to hasten the final disappearance of the germs after recovery, antiseptic solutions have no advantages over salt water. At the present time, sprays and insufflations have been practically abandoned, and irrigation remains as the accepted method of local treatment. This process has undergone great change since its first introduction. Its earliest purpose was to disinfect. The solution used was one of bichloride of mercury, 1 to 2,500; the irrigation was done through the nose only. Later, fluid was also introduced into the mouth, if possible. The irrigation was performed every fifteen minutes and kept up for five minutes. The children were left in their cribs and were not wrapped. Fortunately, most of the nurses' time was spent in refilling the little syringe. But little benefit was derived from this style of irrigation, and it was discontinued after a sufficiently long trial. There followed a period of spraying. Various medicaments were used in the sprays and various forms of apparatus were employed for their application. At one time the children were all brought to the big compressed-air cylinder: at another, heat was employed to furnish the power, and every patient had its own apparatus, consisting of an alcohol lamp and support and a little spherical metallic boiler with an atomizer attached. The possibility of an explosion lent the added charm of uncertainty to this method.

After a term with the sprays, irrigation was returned to in a modified and much improved form. By this method of treatment, as at present practised, the attempt is made to cleanse, as thoroughly as may be, the infected areas and to lessen pain. The frequent cleansing of a diphtheritic throat and nose contributes to the comfort of the patient; it removes decomposed membrane and thus lessens the absorption of products of putrefaction; it, furthermore, improves markedly the odor of the breath. Finally, hot irrigation affords the best means of relieving the intense pain frequently present when the throat is much swollen, by reason of the great amount of accompanying non-diphtheritic inflammation.

Preparatory to irrigation, the patient should be made comfortable and accessible. Adults may be irrigated in bed. Children are best placed on a table, where they are wrapped in a sheet or blanket and protected by a thin rubber sheet. A rubber-covered pillow and Kelly's pad—for drainage—are desirable. Either a fountain or a hand-ball syringe is necessary; the former expedites matters for hospital use; the latter furnishes greater force when it is required to clear a nose obstructed by pseudo-membrane. The nozzles are best made of hard rubber, one form for the nose and one for the throat. The nasal tip should fit the nostril tightly, so that the fluid introduced into one nostril shall escape from the other. The tip for the throat should be of sufficient length so that, after a preliminary washing of the mouth, it may be pushed well back, act as a tongue-depressor, and render it possible to wash the pharynx. The patient will probably gag and thus assist. The nose should be washed first, and every child should have its own tips, kept in an antiseptic solution. The fluid should be delivered in a single stream from a hole in the end of the tip. All the fittings of the syringe should be of hard rubber.

Exhaustive comparative trials were made with several solutions as to their effect on membrane and on persistence of Klebs-Loeffler bacilli: bichloride of mercury of different strengths, peroxide of hydrogen, and salt water. The last—a teaspoonful to the quart—was finally selected. It answers every requirement for either hospital or private use. It is cheap and always available, requires the very minimum of time and experience to prepare, is harmless if swallowed, as some of it must be, and is thoroughly cleansing and non-irritant. The temperature most frequently used is 110° F. If there are excessive pain and swelling, this may with advantage be run up to 138° F. Concerning the frequency of irrigation, each case is a rule unto itself. There are cases in which, for a day or two, the patients are undoubtedly benefited and relieved by being irrigated as often as every hour—when awake; more frequently, three or four times a day is often enough. Some persistently refractory children are better not irrigated at all. It is surprising, however, how quickly even the smallest children, if properly handled and wrapped, learn not only to be tractable, but even to render assistance by way of open-

ing their mouths and lying still. To irrigate well requires experience under proper training. There is no evidence that irrigation favors infection of the middle ear.

The old-time practice of making applications to the larynx, in cases of croup, by means of insufflation or by a brush, gave way to inhalation. Calomel, as a sublimate, was used extensively. It produced coughing, sometimes emesis. It is no longer in use, so far as I know. Sulphur has been used in much the same way and with equally unsatisfactory results. Medicated steam is still in use. Properly applied, it is undoubtedly beneficial in some cases—especially to prevent the necessity of reintubation.

The nasopharynx, the larynx, and the eye are the three most dangerous sites for a diphtheritic deposit. Each of these lesions gives a distinct set of conditions and, aside from antitoxine, requires its individual line of treatment. In nasopharyngeal diphtheria, the danger is toxæmia, with resultant heart failure, early or late. There may be abundant membrane on the tonsils and anterior pillars and but slight danger. The rapidity of absorption of toxins from the posterior nares and nasopharynx is, of course, explained by the scarcity of protecting connective tissue and the abundance of lymphatics beneath the mucous membrane. The danger seat is largely out of sight, and instrumental meddling is strictly contraindicated. The anterior cervical glands will give warning unless the disease is so rapid as to be properly called malignant. Indications of approaching danger travel, also, along the lines of the motor branches of the pneumogastric nerve. Nasal voice, coughing, and regurgitation in swallowing are usually the first signals. These changes are only too often the precursors of a change in the heart's action. A rapid and feeble, or worst of all, an intermittent, pulse indicates a most serious condition. Absolute rest—morphine may be a most valuable adjunct in securing this—stimulation, and every possible attention to the nourishment of the patient cover the ground of early available treatment. Gavage is frequently indicated. Paralysis of the abductors of the vocal cords may necessitate intubation. I wish to reiterate the importance of paying the strictest heed to the earliest, and even the slightest, indications of oncoming diphtheritic paralysis. The disappearance of such indications may be a question of weeks or of months, but so long as they are present they mean unmistakably a dangerous and critical condition. The heart is peculiarly susceptible to diphtheritic toxins, as not only its nerve, but its muscular structure also, is liable both to parenchymatous and to interstitial changes. When the paralysis has affected groups of muscles, as in an arm or a leg, faradism, passive motion, and massage may be of service, when the affected muscles begin to show improvement. When there is no tendency to spontaneous improvement, treatment is of no avail. Permanent disability, such as multiple sclerosis or hemiplegia, is usually due to hæmorrhage into the spinal cord or brain.

In diphtheritic laryngitis, stenosis is the immediate danger. Toxæmia is improbable, unless the lesion extends below the larynx. Either of the operations for the relief of laryngeal stenosis introduces a large foreign body into the larynx and trachea, acts as a contributing cause to the development of pneumonia, interferes with nutrition, and favors the extension of membrane. The avoidance of an operation is, therefore, the first consideration. Ventilation, air space, and temperature are of great importance; a ward temperature of 72° to 76° F.; frequent change of air without draughts; one hundred and fifty square feet of floor space for each patient (in a room not less than ten feet high); freedom from the presence of pneumonic or septic patients, are the desiderata for all cases. In selected cases, hot applications to the neck, steam inhalations, and, rarely, emesis are beneficial. Poultices are contraindicated when they are irritating; when used, they must not be allowed to cool before renewal. Fifteen minutes is about the period of utility of a well-made poultice. To poultice for an hour at intervals of two hours is often a good method. In late cases, with detached or probably detachable membrane, emesis may be indicated—if it is not too exhausting. To apply steam to the best advantage to a child, a room must be available in which the atmosphere can be kept warm and moist by escaping steam—medicated as one may prefer. A croup kettle is satisfactory with adults only. Keeping a child as quiet as possible—to reduce the requisite amount of oxygen to a minimum—is, of course, desirable.

It is very gratifying to a physician to feel assured that a patient was intubated at exactly the right time; not too early, thus, perhaps, unnecessarily transferring a case from a class with low mortality to a class in which the mortality is much higher; not too late, thus possibly nullifying the benefits otherwise to be derived from the operation. The slightest insufficiency in respiration—otherwise incapable of quick relief—calls for operative interference, and sufficient breathing may be so labored that an operation is indicated. A child that cannot sleep needs relief, even though getting enough air. After prolonged exertion, a child may be too weak to struggle; this condition of apparent rest must not be mistaken for sleep. The pulse will tell the difference. Indications of interference with the venous return, such as cyanosis, or diminution of the respiratory murmur, especially at the bases (indicating a beginning exudation of serum into the air vesicles), should be relieved at once. If a patient is progressively getting worse it is better to be a little early than a little late. The above last-named condition is a grave hindrance to recovery.

In cases in which the pseudomembrane has extended below the larynx (this can be told with considerable certainty by the character of the breathing), and in cases in which the nasopharynx is extensively involved, primary tracheotomy is indicated. In this operation, in small children, usually both the cricoid and the upper

two or three rings of the trachea are cut. Concerning the operation I will only say, that, as soon as the trachea has been reached (it is easily distinguished either by the finger or by the eye), its position should be fixed by means of a tenaculum inserted into its anterior wall, just off the median line. The initial incision into the air-passage should be the upper extremity of the final incision, and should be enlarged with a blunt-pointed bistoury.

The O'Dwyer tube of to-day is made of vulcanized rubber strengthened by a metallic lining. It consists of a body, retention-swell, neck and head. The outside anteroposterior diameter of the body, retention-swell, and neck is the same. The outside transverse diameter of the retention-swell at the middle of its fusiform enlargement is slightly greater—for each size of tube—than is its anteroposterior. The cricoid cartilage is the only completely cartilaginous ring through which the tube passes. Its lower border is the smallest part of this ring, and is the "measure" for the outside dimensions of the tube. This lower border is slightly elliptical—major axis anteroposterior. The difference between the two diameters at one year old is about 1 mm.; at four years, 1½ mm.; at ten, 2 mm.; in adults, 3 mm. This excess of the anteroposterior over the transverse diameter is continued downward in the trachea beyond the point reached by the lower end of the tube. Now, remembering that the proportions between the diameter of the retention-swell are the reverse of those of the cartilage, it is evident that the tube rides in the cricoid; the line of supporting contact being the lower border of the cartilage and a line drawn round the tube just below the maximum part of the retention-swell. The true vocal cords, while immediately below the head of the tube, do not carry any weight, in fact, are entirely relieved from continuous pressure, taking their origin, as they do, from the upper border of the cricoid. Their function, in intubation, is, by their approximation, to prevent the tube from being coughed up too easily. The frequency with which tubes are coughed up demonstrates the weakness of their resistance. It requires, on the other hand, considerable pressure to push the middle of the retention-swell through the cricoidal ring. If this is done, of course, the head of the tube goes below the vocal cords and beyond the reach of the finger. In such a case, excited efforts (and they are very likely to be excited) with the extractor may push even the head of the tube below the cricoid. The extractor should not be used unless the head of the tube can be felt by the finger. bimanual extraction without the instrument being safer and, furthermore, avoiding such possible displacement of the larynx as to allow the tube to slip forward and upward until its head rests under the hyoid bone. The possibility of this complication should be borne in mind whenever a tube disappears from its usual position after ineffectual attempts at instrumental extraction.

While a child is carrying an intubation tube, certain

lines of special treatment are indicated. In the first place, careful attention must be given to the drainage of the air-passages, and irrigation of the throat is not desirable. All mucus and membrane coughed up, but not expelled, should be removed by the finger. The child is best laid on a table, wrapped. (If a patient's cough is insufficient, it may be strengthened by the introduction of a little whisky into its throat.) This procedure is carried out regularly, the frequency varying with the requirements. Nasal irrigation is permissible.

In feeding, whenever possible, the child should drink from its cup in the ordinary way, and this is possible in many cases during the entire intubation period. Once in a while the Casselberry method is of service. If a child cannot swallow in a normal posture, however, gavage is usually the remedy. If gavage is contraindicated, as by swelling, hæmorrhage or pain, semi-solid food may be given. Ice cream may tide one over a difficult day or two. Rectal feeding, of course, may be resorted to. The stomach, however, is usually accessible in some way.

Internal medication should be reduced to a minimum. If the case is complicated by an exudation of especially tenacious mucus, the inhalation of medicated steam should be tried. The worst cases are those complicated with a nasopharyngeal lesion or with extension of membrane below the tube. Here, on account of the threatened heart failure, absolute rest is essential, and the use of morphine by hypodermic injection is the one way to get it. The influence of this drug may be kept up for several days if necessary.

The stay of the tube should be as short as possible. In regard to this, there is, in each case, a number of things to be considered: the degree of inflammation in the larynx, as evidenced by the amount of mucus and membrane coughed up; the appearance of the membrane in the throat, if there is any; the temperature, pulse, and general condition; the age—the younger the patient, *cæteris paribus*, the longer the stay; the duration of the disease, and its duration prior to the administration of antitoxine. These are all matters of importance and make each case a law unto itself. In all early cases, the tube should be removed by the fifth day at furthest. The morning is the best time for extubation.

When a tube has been removed, the first consideration is to avoid the necessity for its return. Sulphate of morphine, from a sixteenth to a twelfth of a grain, given fifteen minutes before extubation, is an excellent precaution. Should dyspnoea recur, poultices, hot baths, narcotics, and steaming are all important aids. A stay of several days in the steam room may be necessary to avoid reintubation. Children under two years generally carry their tube two weeks or longer, so that in these cases two or more reintubations are regularly necessary. Other causes of "retained tube" are: Congestion, causing a more or less rapid return; paralysis, diphtheritic or due to the pressure of the tube; granulations, following ulceration; and, later, cicatricial contraction. In

sthenic cases, having had a laryngeal condition only, depletion may very well be of distinct advantage. Leeches and even purgation are indicated. In cases of paralysis, the return of the tube must be immediate. In granulation cases, several days may elapse. Smaller tubes, or "special" tubes to relieve or vary the site of pressure, are indicated, and in the latter cases medicaments placed on the outside of the neck of the tube are used. In the late cases, in which cicatricial tissue plays a part, tubes larger than the age of the patient calls for, left in for long periods of time, have effected several cures. In general, neither tracheotomy nor thyrotomy is of any avail in these protracted cases. O'Dwyer said: "If you get rid of an intubation tube by means of a tracheotomy tube, you will, later, in each case get rid of the tracheotomy tube by reintubation." I have still to hear of the exception that proves this rule.

Some minor changes for purposes of asepsis and convenience have recently been made in intubation instruments, but, so far as concerns a perfect appreciation of conditions in laryngeal diphtheria and of all essentials requisite to meet these conditions, O'Dwyer may certainly be called the author and finisher of intubation of the larynx.

A diphtheritic eye requires a specialist and two experienced nurses. Many doctors, nurses, and others having to do with the care of diphtheria patients suffer frequently from infected fingers. This infection often produces paronychia. It usually, however, remains superficial, and recovery comes about without an operation, through the influence of heat and moisture. If, on the other hand, throbbing pain is present, worse at night, showing subperiosteal effusion, immediate incision is indicated.

244 EAST NINETEENTH STREET.

Correspondence.

LETTER FROM TORONTO.

The Late Dr. J. Archer Watson.—The Matriculation Requirements of McGill University.—The Chinese in Canada.—The Hospitals of the Province of Ontario.—Queen's Medical College, Kingston.—Barber-shop Sanitation in the Province of Quebec.—A Canadian Surgeon Wins the Victoria Cross in South Africa.—The Protestant Hospital for the Insane, Verdun, Quebec.

TORONTO, April 13, 1901.

DR. J. ARCHER WATSON, a well-known practitioner of Toronto, was instantly killed on the morning of the 11th inst. The doctor, who was an enthusiastic horse-back rider, started out on that morning to ride out to Weston, his former home, a distance of some ten miles. While he was crossing a railroad at Lambton Mills his horse, a young and spirited animal, became very restive and backed on to the track in front of an approaching

train, throwing the rider violently against the engine boiler. Both rider and horse were instantly killed. Dr. Watson graduated from Trinity Medical College with the class of 1885, and shortly after graduation received an appointment in the anatomy department of that institution, which he subsequently relinquished. His funeral, which took place this afternoon, was attended by a large concourse of physicians. He was unmarried.

McGill University purposes raising its standard of medical matriculation, and the change will come into effect in September, 1902. After that date all candidates will be required to show at least a practical knowledge of chemistry and a sound theoretical acquaintance with physics, statics, and dynamics. Greek, German, and French will be the only optional subjects after that date, and one or another of these must be taken. Later on, it is the purpose of the authorities to still further raise the standard by requiring all candidates before matriculating in medicine to show that they have taken the first year arts course. Not long ago McGill lengthened its session from six to nine months and established a combined arts and medical course. Last year great improvements were made in the pathological department, and with the improvements which are in contemplation for the present year, combined with these advances in matriculation requirements, McGill hopes to lead the world in its medical department. The present changes in the matriculation standard are designed to keep students constantly at work, not allowing of their participation in other work outside their college course.

The question of Chinese labor as affecting Canadian labor is at the present time being inquired into by a royal commission appointed by the legislature of British Columbia. This commission has been sitting in Victoria, B. C., and last week summoned Dr. O. M. Jones, health officer of that place, to give evidence as to the sanitary conditions of the Chinese quarters and the habits of life of these Orientals. Dr. Jones stated that lately their quarters had been much improved, owing to the erection of new buildings, but that these people paid little attention to the well-known laws of sanitation. He considered that they were constantly a slight menace to the health of the general public, on account of fresh arrivals from Chinese ports which were notoriously infected with small-pox all the year round. Personally, he stated, they were very eager to be vaccinated. Referring to the existence of leprosy, he had attended to about five cases. The Chinese took every pains to hide cases of leprosy. He had not observed a distinct case of leprosy among the children of white people. Some time ago there had been an epidemic of mumps among the Chinese in Victoria, and many of the clerks in the banks contracted the disease, which he considered had been due to their handling the money of the Chinese. As to their calling in physicians when sick, the wealthy class did get the white doctors. The Chinese hospital was under the supervision of

the medical health officer, who made regular visits, and Dr. Jones thought this a better plan than appointing a resident house physician.

The annual report upon the hospitals, refuges, etc., of the Province of Ontario has just been issued, and it shows that there are between fifty and sixty hospitals in this Province, all receiving their share of governmental aid. That the public confidence is increasing in these institutions is shown by the fact that there has been a large increase in the hospital population over the previous year; and there has been a great improvement in the refitting, furnishing, and sanitary conditions, which, combined with the successful medical and surgical attendance and nursing, helps to increase the faith the public have in their efficiency. On the 1st of October, 1900, the number remaining in the various hospitals of the Province was 1,893. The number of patients admitted during the year was 27,061, and the number of deaths during the year was 1,451. The total number of days' stay was 739,816. The Ontario government contributed \$110,000, and the balance of the total revenue amounted to \$498,579.17. The expenditure amounted to \$570,150.36, being an average daily cost of 83½ cents for each patient. There are one hundred houses of refuge, etc., in the Province, with a population of 5,042, and the yearly expenditure for their maintenance is \$234,602.53.

The annual convocation ceremonies of Queen's Medical College, Kingston, Ont., were held on the evening of the 10th inst., when Dr. Herald, the secretary of the faculty, performed the ceremony of presenting the Dean Fowler Scholarship, which has lately been founded by the faculty and medical graduates of Queen's in the United States and Canada, in commemoration of the life-long services of Dr. Fife Fowler to Queen's medical faculty. Dr. Fowler came to Kingston from Edinburgh in 1854, at the time when Queen's medical faculty was being founded, and received the appointment of professor of materia medica, which he held until 1878, when he was advanced to the chair of medicine, which he only a short time ago relinquished to Dr. James Third, who was at that time superintendent of the Kingston General Hospital, and whose death is expected daily from an attack of apoplexy which occurred some weeks ago. Dr. Fowler was appointed dean in 1883, and that title he still holds. During this long period of forty-six years he has done good work for Queen's, and in recognition of his past services it was decided that a scholarship in medicine would be a proper tribute to those services. The scroll setting forth the purpose of the scholarship was presented to the chancellor, Sir Sanford Fleming, and Dr. Fowler made a suitable reply, referring to the fact that, of all the founders of Queen's Medical Faculty, he alone remained alive at that day.

In the matter of barber-shop sanitation, the Province of Quebec easily leads all the other provinces of the Dominion. A barbers' association is also in existence and has been the means of doing much good toward the re-

form of the habits of the tonsorial artist. This association extends its jurisdiction over towns and cities of 5,000 and upward. It and the existing conditions have been created by act of Parliament, and according to this provincial law no barber can work in a factory during the day-time and conduct a barber-shop on Sundays and week-day evenings. The law as it now stands compels barbers to take out a license or abandon business, and the rules of the association make it obligatory upon customers who may be affected with any skin or scalp disease to possess their own razors, soap, brushes, etc., which are kept in a specially constructed cabinet approved by the Provincial Board of Health. The law is said to be working satisfactorily, antiseptic measures are carried out, hot water is in every barber-shop, and on every hand the customer and the barber are being protected from unsightly skin diseases.

A Canadian doctor has just received the Victoria Cross for distinguished bravery on the South African battlefield. Dr. H. E. M. Douglass, who is in receipt of this unusual honor, graduated from Queen's Medical College, Kingston, in 1897. He was attached to the Gordon Highlanders as surgeon, and it was at the battle of Maegersfontein that he so signally distinguished himself. He was with the Black Watch on its death march, and, it is stated, when the fire opened, though slightly wounded himself, crawled amid the hail of bullets to the head of the column. Here the officers of his regiment were lying about dead or wounded. He dressed the wounds of all within reach, and made his way back safely, and being then the senior officer, rallied the scattered ranks of the Gordons and led them out of action. While performing this duty he was wounded by a bursting shell, which carried away a portion of one cheek.

The annual report of the Protestant Hospital for the Insane, Verdun, Quebec, shows that the number of patients in that institution is on the increase. Since its establishment, in 1887, there have been admitted 1,418—766 males and 652 females. There were 497 patients treated in this hospital during last year, of whom 265 were males and 232 females. Ninety-three patients were discharged during the year. Of these, fifty were men and forty-three women. Fifty-two were discharged as having recovered, twenty-eight improved, and thirteen unimproved. This is a discharge rate of 66.90 per cent. and a recovery rate of 37.41 per cent., a marked improvement over the previous year, when these percentages stood 52.42 and 33.33 respectively. The average period of residence of those permanently discharged was a trifle over eleven months. There were thirty-five deaths during the year—twenty-two of men and thirteen of women.

The Austro-Hungarian Hospital.—We are informed that the erection of the Austro-Hungarian Hospital, on the site of the East Side Dispensary, at 322-324 East Third Street, New York, is to be proceeded with forthwith. The hospital is to be devoted to the treatment of the poor of that section of the city.

Therapeutical Notes.

Echinacea Angustifolium in the Treatment of Hæmorrhoids.—Dr. E. V. Hall, of Conroy, Ohio (*Cincinnati Lancet-clinic*, March 23d), has found rectal injections of the fluid extracts of hamamelis and echinacea very efficacious in the treatment of internal hæmorrhoids. He gives the following formula:

℞ Fluid extract of echinacea 1 ounce;
Fluid extract of hamamelis 2 ounces;
Distilled water 1 ounce.

M. S. Inject two fluid drachms after each stool.

A slight burning sensation follows the injection, he says, but it soon passes away, giving place to a peculiar cooling effect. In one instance he has thus cured hæmorrhoids for which an operation had been recommended as the only means of cure.

For Eczema.—The *Journal des praticiens* for March 23d mentions the following ointment as giving excellent results in some cases of eczema:

℞ Camphorated naphthol 7½ grains;
Zinc oxide 75 “
Petrolatum 750 “

M.

Guyon's Lubricant for Instruments.—According to the *Journal des praticiens* for March 23d, Professor Necker uses the following for lubricating instruments, especially catheters and urethral sounds. It is said to possess exceptional lubricating qualities besides being antiseptic and non-irritating:

℞ Corrosive sublimate $\frac{30}{100}$ ths of a grain;
Water 375 minims;
Powdered soap 750 grains;
Glycerin 375 minims.

M.

Ichthyol in Erythema Nodosum.—In a letter from London, by Dr. Raymond Crawford, published in the *Therapeutic Gazette* for March, Dr. Brownlie is cited as recommending the following formula:

℞ Ichthyol 2 drachms;
Alcohol, }
Ether, } each 3 “

M. The alcohol and ether are first mixed, and then the ichthyol added; else an insoluble deposit is formed. Painted on, it is said to relieve the burning pain speedily. Dr. Crawford himself recommends a paint consisting of a drachm of ichthyol in an ounce of collodion.

For Amenorrhœa.—*Revue médicale* for March 27th gives the following:

℞ Crystallized apiol 1 part;
Sterilized oil 5 parts.

M.

One cubic centimetre (fifteen minims) may be injected subcutaneously every day.

An Ointment for Intertrigo.—We find the following formula in Reed's *Text-book of Gynecology*:

℞ Zinc oxide, }
Bismuth subcarbonate, } each 30 grains;
Carbolic acid 10 drops;
Vaseline 1 ounce.

M. To be smeared on the affected surface.

NEW YORK, SATURDAY, APRIL 20, 1901.

THE GROWTH OF THE AMERICAN MEDICAL ASSOCIATION.

As the time draws near for the association's next annual meeting, interest in its affairs naturally grows more active among the profession at large. As to the meeting itself, which is to be held in St. Paul on the 4th, 5th, 6th, and 7th of June, there can be but one opinion and but one confident expectation, namely, that it will be at least the equal of any former meeting of the same body, whether from the point of view of the scientific work that will be done or from that of a reunion of the best elements of the American profession. As one annual meeting after another approaches, however, one's thoughts turn more and more on questions more closely bearing upon the association's future usefulness than most of the proceedings that are likely to mark the occasion. The American Medical Association has accomplished a great work, but is it, as at present organized, fitted in the best possible manner for the work that is yet before it? There are those—and they are among the association's best friends—who, recognizing fully that it was originally organized in a way admirably fitting it to cope with the problems of half a century ago, are inclined to think that changed conditions call for some modification of its machinery if it is to keep on doing for the profession the best that can be expected of such a body.

When the association was organized, American medicine was in a decidedly unpromising state. There was, to be sure, no lack of brilliant and progressive men in the profession, but the teaching faculties were almost entirely irresponsible bodies, issuing at their pleasure diplomas which, while certifying to but little that a man could be proud of, gave their holders unquestioned prestige with the general public. Everybody had the right to practise medicine, and quackery was rampant. Authori-

tative pronouncements by the better class of physicians were required to educate the people up to the point of remedying these evils. Such have proceeded from the American Medical Association and from other medical organizations, and they have slowly taken effect. They were authoritative in proportion as they came from a representative body. It was seen at the outset that this would be the case; hence the delegate system in the association's organization.

But the delegates have now become so numerous, about fifteen hundred in all, that, though there are always many absentees, the general session is almost sure to be unwieldy on occasions when a conflict of opinion is to be settled by a vote, many uncalled-for speeches are apt to be made, not a few of the voters fail to get an adequate idea of the merits of the question, and emotion rather than calm judgment is prone to carry the day. All this hinders the real purposes of the meeting so far as legislative action is concerned, and it diverts men's minds from the scientific work in hand, to say nothing of the waste of time entailed. Quasi-legislative action on the part of the association—and by that term we mean the adoption of resolutions, memorials, and the like, calculated to influence State and national legislation—seems to have become less and less important of late years, for the defects which it was formerly needed to correct have been almost wholly remedied. A decided reduction of the number of delegates, the proportion for each constituent body remaining the same, would, it seems to us, enhance the scientific work done in the sections and give time for a greater number of formal addresses, papers of general interest, and demonstrations. There need be no limit to the number of non-voting members, so that the attendance at the meetings would go on increasing as it has done up to the present time. In short, we can see no objection to a decided curtailment of the representative element, and we believe that it would prove advantageous. Such a move, we are quite aware, would involve practically a reorganization of the association; if our ground is well taken, however, why should not a reorganization be effected?

THE PATHOLOGICAL EXHIBIT IN ST. PAUL.

LAST June we had the pleasure of commending the enterprise and good judgment of some of our Indiana brethren as shown in the exhibition of pathological specimens given in connection with the Atlantic City meeting of the American Medical Association. We were convinced that it could not have failed to make a most favor-

able impression, and we are glad to have our view confirmed by the announcement that a display of practically the same scope is to be made in St. Paul in June, this time under the association's official recognition and as an integral part of its work. The committee in charge of the St. Paul exhibition, consisting of Dr. Frank B. Wynn, of Indianapolis; Dr. A. P. Ohlmacher, of Gallopis, Ohio, and Dr. Hugo Summa, of St. Louis, has recently issued a circular of information from which we infer that a similar exhibition is hereafter to be a feature of all the association's annual meetings.

Gross pathological specimens, it is stated in the circular, will naturally constitute the greater part of what is to be displayed, but the committee add that they "will seek to present a wide range of practical scientific demonstrations, imposing only the condition that they bear absolutely no commercial impress." The educational object is to be kept constantly in view, particularly that of demonstrating the fundamental relationship of pathology to diagnosis, therapeutics, and sanitary science. In addition, however, to the pathological specimens, the committee will make an effort to present demonstrations of research and experimental investigation, which, it is quite properly remarked, will tend to stimulate original inquiry among the members of the association, all of whom are appealed to to contribute specimens. It is suggested that in many instances such contributions may advantageously be made in connection with papers read before the sections. Besides their appeal to individual members of the association, the committee urges upon State and other medical societies that they should select representatives to collect and present material on their behalf. Substantial cooperation is expected on the part of medical colleges, hospitals, laboratories, and various scientific institutions, among them, we hope, the Army Medical Museum.

It is announced that an energetic local committee is charged with securing suitable quarters for the exhibition, separate and distinct from those of the commercial exhibits. Contributors are asked to have their material well in hand by the 1st of May, and to furnish the committee with complete lists of their specimens by the middle of that month. Institutions will be encouraged to present groups of specimens illustrative of some particular phase of pathology or bacteriology, and will be permitted to maintain them intact, but smaller collections and single specimens entrusted to the care of the committee will be disposed in the manner best suited to display their instructive features. It is asked that, so far as

possible, all pathological specimens be accompanied by a history of the case and, unless the condition is so typical as not to call for it, a description of the specimen. Copies of the circular—which, by the way, is remarkably well written—together with further information, may be had by writing to Dr. Frank B. Wynn, No. 18 East Ohio Street, Indianapolis, to whom and to his fellow-members of the committee, we must add, the physicians of the whole country should feel indebted for their intelligent and zealous management of this most important undertaking.

THE ROCKY MOUNTAIN INDUSTRIAL SANATORIUM.

IN our issue for April 6th we briefly announced the incorporation of this institution. We have known in a general way for the past two years of the effort to establish it, so that at least the plan is not one that has been hastily formed. Some such means of aiding in the fight against consumption has been needed in this country ever since the value of the climatic and pure-air treatment of incipient tuberculous disease came to be generally recognized. Similar institutions are in successful operation on the continent of Europe, if we are not mistaken, and it cannot be doubted that their establishment in all civilized countries is but a matter of a little time.

As we have often pointed out, and as has been insisted upon by many others, a person in the curable stage of pulmonary consumption cannot, as a rule, be safely allowed to return to his former place of abode and resume work under the old conditions as soon as his symptoms have yielded, no more bacilli are to be found in his sputum, and he feels restored to health and strength. Even in the most favorable cases a prolonged stay in the locality found to be suitable is a most necessary precaution, and in many instances the reclaimed consumptive can never go back to his former life with impunity. But health resorts do not abound in opportunities for remunerative work; how, then, shall a person whose disease has been checked be enabled to live, provided he is not a person of wealth? He cannot go home, for fear of sealing his doom, and he cannot remain with no means of support.

It is precisely to meet this dilemma that an industrial sanatorium is designed. The one under consideration is represented to us by a well-known Denver physician as having been most carefully organized with a view to a wide field of usefulness, and not for pecuniary profit to its promoters. Necessarily, a large sum of money will be required to establish and maintain the actual sana-

torium. At present it exists only on paper, but the proverbial energy of the people of the West may well be trusted to hasten its material existence. Not that Colorado alone is at work, for we are assured that prominent physicians and business men in all parts of the country are cooperating, but the task of organization and administration must almost of necessity fall upon the people of Colorado. They undoubtedly realize that it is far better for their interests to have their consumptive immigrants intelligently and systematically cared for in sanatoria than to have them scattered among the general population, and they can see, too, that the competition of even large industrial institutions, provided they are properly managed, is a matter which they can afford to ignore. Moreover, it has for some time been no easy task for tuberculous patients to secure suitable quarters with the householders. Consequently, not only from the economic point of view, but also from the sanitary, the establishment of large sanatoria of the sort in question is most desirable.

THE PHYSICIAN'S LIABILITY WITH RESPECT TO ANSWERING CALLS.

A SPECIAL communication to the *New York Times* for April 5th states that the Supreme Court of Indiana decided on April 4th, in the case of *Hurley v. Weddingfield*, that a practising physician was not legally bound to attend any patient for whom he was called, although he might have acted as family physician in the past, and that he was not liable for damages for refusing to answer calls. Dr. Weddingfield had been summoned three times to attend the wife of Mr. Hurley and had declined on each occasion, even though offered his fee in advance. It was alleged that in consequence of the lack of medical aid the woman's death had ensued, for which a claim was made of \$10,000. The ethical aspect of the case we are not in a position to discuss, being ignorant of the facts on both sides. It is conceivable that many different conditions might exist which would exonerate a practitioner from any ethical obligation to answer a call—not only imperative conditions, such as ill health, his own urgent private affairs, etc., but even questions of mental attitude—all of which could only come under the overruling demand of "common humanity," obeyed of all good physicians when the case was one of instant life and death, or other aid was unobtainable. Such moral obligation is only a part of the general obligation of humanity to afford aid according to its means and capacity *in extremis*. But the idea that it should be legally compulsory upon every physician to attend any one who might summon him, and under all and every circumstance, would be to reduce the practitioners of

medicine to servitude, and would be too intolerable a burden to be maintained. We do not see how the decision could well have been given otherwise.

THE MINNESOTA MARRIAGE BILL.

THE Chilton marriage bill for Minnesota, having passed both houses, is now dangerously near becoming, if it has not already become, law for that State. This bill provides that, henceforth, every candidate, male or female, for matrimony in Minnesota, must undergo a medical examination before a license to marry can be obtained. The object of such medical examination is, of course, by preventing "the marriage of the unfit," to exclude from the right of procreation all persons having a psychopathic, tuberculous, or venereal taint. To say nothing of the manifold methods by which such restriction can be evaded, it is clear that for it to be at all effective, every woman who henceforth desires to be married in the State of Minnesota must be subjected to a thorough physical exploration of her genital organs, both internal and external. If this examination is not exhaustively and impartially made, the whole affair becomes a perfunctory farce, and its very enactment, being thus rendered valueless and unnecessary, is humiliating and degrading; if it is enforced, how long are the women of Minnesota going to put up with it without rebellion? These are points which we shall watch with interested curiosity.

THE HEALTH OF HAVANA.

IN all our administration of Cuban affairs since we took possession of the island there has been nothing more creditable than what we have accomplished in sanitation under very discouraging circumstances. By the last report of the chief sanitary officer of Havana, Major Gorgas, we learn that the death rate for the month of March was only 26.28 in a thousand, and that from March 23d to the date of the report, April 6th, there was not a case of yellow fever. The subsidence of this disease is largely attributed to the systematic destruction of mosquitoes over a large area around each focus as it has been recognized.

GASTROPTOSIS AND THE CORSET.

WOMEN may perhaps escape at least one of the evil effects ascribed to the corset—that, namely, of falling of the stomach—if in their girlhood they do not don the stays at too early an age. At least, Rostoski (*Münchener medicinische Wochenschrift*, 1900, No. 40; *Wiener klinische Wochenschrift*, January 24th) has found gastroptosis quite exceptional in chlorotic girls who did not begin to wear the corset before attaining the age of fourteen years, but very common in those who began its use at an earlier age.

News Items.

Society Meetings for the Coming Week:

MONDAY, April 22d: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, April 23d: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, April 24th: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.

THURSDAY, April 25th: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private) (annual); Pathological Society of Philadelphia (conversational).

FRIDAY, April 26th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, April 27th: New York Medical and Surgical Society (private).

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending April 13, 1901:

DISEASES.	Week end'g Apr. 6		Week end'g Apr. 13	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	29	11	29	14
Scarlet Fever.....	725	44	619	50
Cerebro-spinal meningitis.	0	3	0	7
Measles.....	289	6	348	10
Diphtheria and croup.....	266	48	285	47
Small-pox.....	42	8	44	11
Tuberculosis.....	269	148	253	173

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from April 6 to April 13, 1901:

BUFORD, O. H., Acting Assistant Surgeon, is granted leave of absence for seven days, with permission to apply for an extension of twelve days.

FARR, CHARLES W., First Lieutenant and Assistant Surgeon, will proceed to Fort Reno, Oklahoma Territory, for duty, to relieve **FRANCIS McCULLUM,** Captain and Assistant Surgeon, who will proceed to San Francisco for transportation to Manila.

NEWGARDEN, GEORGE J., Captain and Assistant Surgeon, will proceed to Fort Mason, California, for duty..

RICHARDS, J. W., Acting Assistant Surgeon, is detailed as treasurer and exchange officer.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending April 13, 1901:

BIDDLE, C., Surgeon. Ordered to the Philadelphia Navy Yard, to relieve **W. G. FARWELL,** Medical Director.

FARWELL, W. G., Medical Director. Detached from the Philadelphia Navy Yard and ordered to special duty in Philadelphia.

GRIFFITH, S. H., Surgeon. Ordered to duty at the Pan-American Exposition, Buffalo, April 25th, in charge of the exhibit of the Bureau of Medicine and Surgery, Navy Department.

SCOFFIELD, W. K., Medical Director. Detached from special duty in Philadelphia and ordered home to await orders.

WAGGENER, J. R., Medical Inspector. Detached from the Naval Hospital, Cavite, and ordered to Mare Island Hospital, California.

WILLIAMS, R. B., Assistant Surgeon. Detached from the Pensacola Navy Yard, Florida, and ordered to the Key

West Naval Station, with temporary duty at Dry Tortugas.

Marine-Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera and plague were reported to the surgeon-general during the week ending April 13, 1901:

Smallpox—United States.

Los Angeles, California.....	Mar. 23-30.....	1 case.
Oakland, California.....	Mar. 16-23.....	1 case.
San Francisco, California.....	Mar. 23-30.....	7 cases.
Washington, District of Co-		
lumbia	Mar. 30-Apr. 6..	2 cases.
Jacksonville, Florida.....	Mar. 30-Apr. 6..	19 cases.
Chicago, Illinois.....	Mar. 30-Apr. 6..	9 cases.
Evansville, Indiana.....	Mar. 23-30.....	1 case.
Terre Haute, Indiana.....	Mar. 18-25.....	1 case.
Clinton, Iowa.....	Mar. 30-Apr. 6..	1 case.
Ottumwa, Iowa.....	Mar. 16-23.....	1 case.
Wichita, Kansas.....	Mar. 30-Apr. 6..	17 cases.
Lexington, Kentucky.....	Mar. 30-Apr. 6..	8 cases.
New Orleans, Louisiana.....	Mar. 30-Apr. 6..	8 cases. 2 deaths.
Shreveport, Louisiana.....	Mar. 23-Apr. 6..	4 cases.
Detroit, Michigan.....	Mar. 30-Apr. 6..	3 cases.
West Bay City, Michigan.....	Mar. 30-Apr. 6..	2 cases.
Minneapolis, Minnesota.....	Mar. 30-Apr. 6..	20 cases.
Nebraska City, Nebraska.....	Mar. 2-23.....	7 cases.
South Omaha, Nebraska.....	Apr. 1-6.....	6 cases.
Manchester, New Hampshire..	Mar. 30-Apr. 6..	6 cases.
Newark, New Jersey.....	Mar. 30-Apr. 6..	2 cases.
New York, New York.....	Mar. 30-Apr. 6..	42 cases. 8 deaths.
Cincinnati, Ohio.....	Mar. 29-Apr. 6..	3 cases.
Cleveland, Ohio.....	Mar. 30-Apr. 6..	35 cases. 2 deaths.
McKeesport, Pennsylvania....	Mar. 30-Apr. 6..	1 case.
Philadelphia, Pennsylvania....	Mar. 30-Apr. 6..	1 death.
Pittsburgh, Pennsylvania....	Mar. 30-Apr. 6..	3 cases.
Steelton, Pennsylvania.....	Mar. 30-Apr. 6..	1 case.
Riverpoint, Rhode Island.....	Mar. 10-Apr. 8..	5 cases.
Charleston, South Carolina....	Apr. 2.....	A few cases.
Memphis, Tennessee.....	Mar. 30-Apr. 6..	22 cases. 1 death.
Nashville, Tennessee.....	Mar. 30-Apr. 6..	14 cases.
Salt Lake City, Utah.....	Mar. 30-Apr. 6..	28 cases.
Roanoke, Virginia.....	Mar. 1-31.....	71 cases. 4 deaths.
Wheeling, West Virginia.....	Apr. 1-8.....	2 cases.
Green Bay, Wisconsin.....	Mar. 31-Apr. 7..	2 cases.

Smallpox—Foreign and Insular.

Buenos Aires, Argentina.....	Feb. 1-28.....	37 cases. 21 deaths.
Prague, Austria.....	Mar. 8-23.....	7 cases.
Antwerp, Belgium.....	Mar. 8-16.....	3 cases. 1 death.
Hong Kong, China.....	Feb. 23-Mar. 2..	9 cases. 7 deaths.
Cairo, Egypt.....	Mar. 4-11.....	1 death.
Paris, France.....	Mar. 16-23.....	6 deaths.
St. Etienne, France.....	Mar. 1-15.....	1 case.
Bradford, England.....	Mar. 8-23.....	3 cases.
Liverpool, England.....	Mar. 16-23.....	2 cases.
Southampton, England.....	Mar. 16-23.....	1 case.
Glasgow, Scotland.....	Mar. 22-29.....	11 deaths.
Bombay, India.....	Mar. 5-12.....	10 deaths.
Calcutta, India.....	Mar. 2-9.....	85 deaths.
Karachi, India.....	Mar. 3-10.....	12 cases. 4 deaths.
Madras, India.....	Mar. 2-8.....	11 deaths.
Progreso, Mexico.....	Mar. 22-29.....	8 cases.
Rotterdam, Netherlands.....	Mar. 23-30.....	2 cases.
Moscow, Russia.....	Mar. 8-16.....	4 cases. 3 deaths.
Odessa, Russia.....	Mar. 8-23.....	13 cases. 3 deaths.
Warsaw, Russia.....	Mar. 8-16.....	9 deaths.
Malaga, Spain.....	Mar. 1-15.....	2 deaths.
Geneva, Switzerland.....	Mar. 2-9.....	1 case.
Manila, Philippines.....	Feb. 16-23.....	1 death.
Ponce, Porto Rico, from beginning of epidemic to Mar. 15,		132 cases.

Yellow Fever.

Port Limon, Costa Rica..... Apr. 6..... 1 case.

Cholera.

Hong Kong, China.....	Feb. 23-Mar. 2..	6 deaths.
Bombay, India.....	Mar. 5-12.....	4 deaths.
Calcutta, India.....	Mar. 2-9.....	26 deaths.
Singapore, Straits Settlements.	Feb. 2-23.....	1 death.

Plague—Foreign and Insular.

Hong Kong, China.....	Feb. 23-Mar. 2..	7 cases. 6 deaths.
Bombay, India.....	Mar. 5-12.....	1,196 deaths.
Calcutta, India.....	Mar. 2-9.....	557 deaths.
Manila, Philippine Islands....	Feb. 16-23.....	7 cases. 6 deaths.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending April 11, 1901:

ALTREE, G. H., Acting Assistant Surgeon. Granted leave of absence of four days from April 15th.

BANKS, C. E., Surgeon. Granted leave of absence for six days from April 15th.

BROWN, F. L., Hospital Steward. Relieved from duty at Boston and directed to proceed to Cape Charles Quarantine Station and report to the medical officer in command for duty and assignment to quarters.

COFER, L. E., Passed Assistant Surgeon. Designated as chief quarantine officer of the Territory of Hawaii, relieving Surgeon D. A. CARMICHAEL.

FRANCIS, EDWARD, Assistant Surgeon. To proceed to New York and report to the medical officer in command, Immigration Depot, for duty.

GAHN, HENRY, Hospital Steward and Chemist. To assume temporary charge of the Purveying Depot during the absence of the medical purveyor.

GREENE, J. B., Passed Assistant Surgeon. Relieved from duty at Berlin, Germany, and directed to proceed to Washington.

GRUBB, S. B., Assistant Surgeon. Granted leave of absence for seven days. Upon expiration of leave, to proceed to Washington and report at the Bureau for duty.

HASTINGS, HILL, Assistant Surgeon. To proceed to Santa Barbara, California, for special temporary duty.

KINYOUN, J. J., Surgeon. Relieved from duty at San Francisco Quarantine Station and directed to proceed to Detroit and assume command of the service. Granted leave of absence for fifteen days.

LAVINDER, C. H., Assistant Surgeon. Bureau telegram granting Assistant Surgeon Lavinder leave of absence for ten days amended so that said leave shall begin April 1st instead of March 27th.

LUMSDEN, L. L., Assistant Surgeon. Upon the departure of Surgeon J. J. KINYOUN, to assume temporary command of San Francisco Quarantine Station.

PECK, F. H., Hospital Steward. To proceed to San Francisco for special temporary duty.

PERRY, T. B., Surgeon. Department letter of March 2, 1901, granting Surgeon Perry leave of absence for thirty days amended so that said leave shall be for twenty days.

Promotion.

Assistant Surgeon H. S. MATHEWSON promoted and appointed passed assistant surgeon, to rank as such from April 7th.

Appointment.

J. A. MONCURE reinstated and appointed acting assistant surgeon, United States Marine-Hospital Service, for duty at the Gulf Quarantine Station.

The Tenement House Bill Signed.—Governor Odell has signed the four tenement house bills which the New York legislature passed on the recommendation of the Roosevelt Tenement House Commission.

The Latin-American Scientific Congress, which was held recently at Monte Video, discussed at great length the subject of yellow fever and its prophylaxis, and also discussed leprosy.

A Proposed State Colony for Epileptics.—The Illinois legislature is reported to be considering the establishment of a State colony for epileptics to involve an initial expenditure of about \$250,000.

A Woman Coroner Appointed in Nebraska.—Dr. Ella E. Summers, a young woman of twenty-six, and a graduate of an Omaha medical college, was recently appointed coroner of Franklin County, Neb. Her uncle was the former incumbent.

The Crusade against the Spitters.—Arrests of men charged with expectorating in public conveyances have been frequent in New York city during the past week, and President Sexton, of the Board of Health, reports that there will be no let-up in the crusade. Most of the magistrates before whom the offenders have thus far been arraigned have been lenient, allowing the men to go with a warning if it was their first offense.

The Attachés of a San Francisco Hospital Honor Retiring Resident Physician.—The attachés of the French Hospital at San Francisco, Cal., recently presented to Dr. J. D. de Chantreau, the retiring resident physician, who has been connected with the hospital for nine years, a bust of Pasteur, costing \$200.

The Municipal Physicians at Munich Strike.—Following the example of the municipal physicians at Leipsic, those at Munich have gone on strike for higher pay and better treatment. All the Munich physicians have declared themselves in sympathy with the strikers and in favor of solidarity in the movement.

A Banquet Tendered to a Naval Surgeon Wounded at Peking.—Surgeon Thomas M. Lippitt, U. S. N., who was one of the marines cooped up in Peking by the Boxers and who was wounded in the siege while helping to train the guns against the Chinese, was tendered a banquet on April 8th at Berryville, Va., by his boyhood friends.

Washington Physicians to Study in European Hospitals.—Dr. Samuel H. Greene, Jr., of the University Hospital (Columbian), and Dr. Edgar P. Copeland, of the Children's Hospital, Washington, D. C., sailed recently on the Cunard steamship *Lucania* for Liverpool for extended study and observation in European hospitals.

Judge Decides in Favor of Christian Scientists in Wisconsin.—Judge Elliott, in the Circuit Court, Milwaukee, recently decided that Christian Scientists were not liable to prosecution under the State Medical law. The Court ruled that the Scientists could no more be held for practising medicine when their means for healing was by prayer than could a minister who prayed at the bedside of the sick and received therefor a fee, either directly or indirectly.

Graduating Exercises.—The graduating exercises of the St. Louis College of Physicians and Surgeons was held on April 9th at St. Louis. There were fifty-two graduates.—The annual commencement of the Baltimore University School of Medicine was held on April 11th. The graduating class comprised twenty-nine men and two women.—The ninth annual commencement exercises of the Barnes Medical College were held at St. Louis on April 12th. There were 110 graduates.

A Marble Bust of Chicago's First Woman Physician.—Friends of the late Dr. Mary Harris Thompson, founder of the Chicago Hospital for Women and Children, which now bears her name, are preparing to further perpetuate her memory by having a marble bust of her made by Daniel Chester French, the Boston sculptor. The bust will find a permanent home in the Art Institute of Chicago. Dr. Thompson was the pioneer woman physician of Chicago.

A Physician is Elected Mayor of Galesburg, Ill.—Dr. William O'Reilly Bradley, a former resident of Rochester, N. Y., was elected mayor of Galesburg, Ill., at the recent municipal election. Dr. Bradley was born in Rochester thirty years ago, and received his medical education at the University of Buffalo. He was elected coroner's physician in Rochester in 1883. His father, Dr. Thomas Bradley, was prominent in Democratic State politics, being at one time chairman of the Democratic central committee of New York State.

A New York State Nurses' Association.—A movement is on foot to form a New York State Nurses' Association, and to that end a meeting has been called for April 16th and 17th at Albany. The meeting will be in the nature of a conference, as a State society cannot be formed with individual membership, but must have the nurses organized in local clubs before the State association is possible.

The Paris Academy of Medicine Discusses the Mosquito.—The mosquitoes of Paris have earned the distinction of attracting the notice of the Academy of Medicine of that city. At its last meeting Dr. de Hove suggested that they might be the means of propagating disease, and proposed that all stagnant sheets of water in the city should be either converted into running water or covered over with a slight layer of petroleum to prevent their breeding. Dr. Laveran, Dr. Chatus and Dr. Proust backed up Dr. de Hove's proposal, but expressed the opinion that Parisian mosquitoes were harmless from the point of view of disease, though undoubtedly a great nuisance.

The Wisconsin Courts Define the Rights of Medical Examiners.—The Wisconsin State board of medical examiners has the right to determine whether an applicant for registration is a reputable resident physician, and its decisions on this question cannot be reviewed by mandamus. Such is the rule recently laid down by Judge Siebecker in the Circuit Court at Madison, Wis. The decision was rendered in the case of Dr. W. M. Caswell, of Hillsboro, against the State board, Dr. Caswell seeking to compel the board to grant him a certificate of registration. The board has been waiting for the disposition of the case before beginning prosecutions against a number of unregistered physicians in different parts of the State.

A Student of Ann Arbor has Bubonic Plague, but Will Recover.—Dr. Victor C. Vaughan, dean of the medical department and one of the most noted bacteriologists in the country, appeared before the State board of health, at Ann Arbor, Mich., on April 15th, and practically acknowledged that the case of the student, C. B. Hare, was one of bubonic plague. He assured the board that there would be no spread of the disease and the student would recover. Dr. Novy, who attends Hare, wears a germ-proof rubber garment that covers him from head to foot, and he also injects preventive doses of serum into himself. Dr. Vaughan told the board that Hare contracted the disease by an accident almost identical with that which occurred in Vienna in 1898. Professor Nothnagle and his assistant, Barisch, were conducting bacteriological experiments on bubonic plague bacilli. Barisch caught the disease and died, as did also Dr. Muller, who attended him.

The Dinner of the Faculty of the Post-Graduate Medical School and Hospital took place on the 15th inst. The president, Dr. St. John Roosa, was toastmaster, and the attendance numbered about one hundred. After dinner, Dr. Roosa paid a tribute to the memory of the late Dr. Hanks. He spoke of the prosperous condition of the institution which, he said, now numbered more students than any similar institution in the world, and referred to the presence of a member of the Fahnestock family, which recently founded a nurses' school in connection with this institution. Mr. Fahnestock replied, and then the secretary stated that in addition to wiping out the debt of \$8,000, the sum of \$15,000 had been invested. Speeches were made also by Professor Allen, Dr. Beaman Douglas, Professor McKiernan, Dr.

Powell, Professor Boldt, Professor Gant, Dr. Weber, Dr. Van Fleet, and Dr. Dana, of Cornell.

The New York County Medical Association.—The annual election of officers of the New York County Medical Association, held on April 15th at 17 West Forty-third Street, resulted as follows: President, Dr. Parker Syms; first vice-president, Dr. Alexander Lamert; second vice-president, Dr. Francis W. Murray; secretary, Dr. Ogden C. Ludlow; corresponding secretary, Dr. M. L. Madura; treasurer, Dr. Charles E. Denison; member of the executive committee (for three years), Dr. C. S. Benedict; member of the nominating committee, Fifth District Branch, Dr. John W. S. Gouley. The membership of this organization has in the last year increased to over nine hundred. The bronze statuette, "Devoir," by Gaudez, was presented to James Taylor Lewis, of this city, counsel to the county and State associations. Dr. E. Eliot Harris, chairman of the committee on legislation and of the special committee, made the presentation speech. He called attention to the importance of the legal status of the association as fixed by the courts and of the work done in securing a special charter, and expressed the gratitude of the association.

The Society of Medical Jurisprudence of New York City met on April 8th at the Academy of Medicine. A paper by Dr. John B. Huber on Faith Cures and the Law was read by Dr. A. W. Warden, the author being absent. The author said: "If the Christian Scientists' position be admitted, a thug might, I submit, upon the same principle be justified in committing murder on the ground that murder is a practice required by his religion. And when a person ignorant of the most rudimentary principles of sanitary science treats those who are sick of contagious disease in wilful disregard of laws enacted to conserve the general health of the community, may he claim respect for his personal liberty to the jeopardy of the lives of his reasonable and sane neighbors?" E. H. Benn, Alfred E. Ommen, and others participated in the debate which followed. The society will hold its eighteenth annual dinner at the Waldorf-Astoria on Saturday evening, April 20th. Eminent speakers, representing all the various professions, will be heard. The following committee is arranging the details of the occasion: Theodore Sutro, chairman; Stephen C. Baldwin, Dr. Carl Beck, Dr. Edward F. Brush, Charles Bulkley Hubbell, Dr. C. A. Von Ramdohr, George W. Cotterill, John C. West, Alfred E. Ommen, James P. Foster.

The New York Academy of Medicine.—At the last stated meeting, on Thursday evening, the 18th inst., the following papers were read: Introduction to the Psychological Study of Backward Children, by Dr. William B. Noyes; The Ætiology of Mental Deficiency, by Dr. Pearce Bailey; Heredity as a Factor in Dull-minded Children, by Dr. T. Alexander MacNicholl; Dullness Due to Eye Defects, by Dr. Charles Stedman Bull; The Function of the Teacher in Ascertaining and Treating Mental Deficiency, by Professor Lightner Witmer, of the University of Pennsylvania; and The City's Obligation to Provide Special Education for Defective Children, by C. E. Melency, Superintendent of the New York Board of Education.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 24th inst., the order will be as follows: The Importance of Preventing Chronic Suppurating Ethmoid Disease by Prompt Local Treatment, by Dr. Clarence Rice; and Nasal Conditions Observed in the Aged, by Dr. Beaman

Douglass. Cases will be presented and new instruments and specimens will be exhibited.

At the next meeting of the Section in Obstetrics and Gynæcology, on Thursday evening, the 25th inst., the following papers will be read: Symphysiotomy, by Dr. Edward A. Ayers; Cæsarean Section, by Dr. E. B. Cragin; Dilatation of the Cervix, by Dr. Henry J. Garrigues; Axis-traction Forceps, by Dr. Egbert H. Grandin; and Version: Indication, Limitation, and Technics, by Dr. S. Marx.

State Medical Society Meetings.—The twenty-eighth annual meeting of the Florida Medical Association was held at Jacksonville on April 10th.—The Medical Association of the State of Alabama met in Selma on April 16th to 19th. A large number of papers were promised for the meeting. A special feature of the meeting was the Jerome Cochrane lecture, by Dr. William Osler, of Baltimore.—The fifty-first annual meeting of the South Carolina Medical Association was held at Florence on April 17th and 18th, the annual address being delivered by Dr. Wharton Sinkler, of Philadelphia, his subject being The Importance of a More General Knowledge of the Diseases of the Nervous System.—The Louisiana State Medical Society held its twenty-second annual meeting at the medical department of Tulane University on April 18th, 19th and 20th. A large number of papers were promised in the preliminary programme.—The Medical Society of the State of Tennessee met at Nashville on April 11th. Officers were elected as follows: President, Dr. D. J. Roberts, of Nashville; first vice-president, Dr. J. B. Murfree, Jr., of Murfreesboro; second vice-president, Dr. L. A. Yarbrough, of Covington; third vice-president, Dr. W. B. St. John, of Bristol; secretary, Dr. A. B. Cooke, of Nashville; treasurer, Dr. W. C. Bilbro, of Murfreesboro. The address of the president, Dr. J. A. Cook, of Jackson, had for its subject The Medical Society, its Advantages to the Profession and Value to the Public. A special address was delivered by invitation by Dr. Wm. R. Pryor, of New York, giving An Analysis of My Ablations for Pelvic Inflammation. The programme was an excellent one, including some fifty papers.

Medical and Chirurgical Faculty of Maryland.—The following is the programme of papers for the annual meeting of this association, which will take place on April 23d at Baltimore: Splenectomy for Wandering Spleen, by Dr. T. A. Ashby; Uterine Myomata and their Treatment, by Dr. T. S. Cullen; A Case of Schönlein's Disease. Death from Acute Glomerulo Nephritis, by Dr. W. T. Watson; The Story of the Ophthalmoscope, Illustrated by Early Publications and Historical Models, by Dr. H. Friedenwald; Intestinal Dystrophia, by Dr. J. C. Hemmeter; Herpes Zoster Ophthalmicus in Loss of the Eye, by Dr. R. L. Randolph; Double Suppurative Chorioiditis in Association with Purpura Hæmorrhagica, by Dr. R. L. Randolph; Remarks on Twenty-five Fractures Treated in March, 1901, by Dr. R. W. Johnson; Tendon Transplantation, by Dr. S. M. Cone: Valvotomy, with Report of Two Cases, by Dr. S. T. Earle, Jr.; Wireless Telegraphy, by Dr. W. Simon; Some of the Causes of the Acute Insanities, by Dr. S. Paton; Experience with Chloretone, by Dr. W. R. Dunton; Should Cold Baths be Used for High Temperatures in Children? by Dr. C. O'Donovan; Cases of Diarrhoea Due to a Parasite hitherto Unobserved in Maryland, by Dr. W. S. Thayer; A Consideration of the Treatment of Hæmorrhoids, by Dr. J. Turner; A Case of Anthrax of the Face. Opera-

tion, Recovery, Exhibition of Patient, by Dr. W. B. Platt; Tumors of the Neck Due to Congenital Conditions, by Dr. R. Winslow; A Case of Typhoid Fever Complicating the Puerperal State, by Dr. A. G. Barrett; Report on Renal Surgery, with Special Reference to Nephrectomy in Renal Tuberculosis, by Dr. F. Martin; The Ætiology of Typhoid Fever and Treatment in Private Practice, by Dr. G. E. Dickinson; Acute Dilatation of the Stomach, by Dr. J. Friedenwald; Rabies, Tabulation of 200 Cases Successfully Treated Prophylactically (Pasteur method), by Dr. N. G. Keirle; Blood Changes in Puerperal Eclampsia, by Dr. E. L. Whitney; The Practical Value of Blood Examinations in Medicine and Surgery, by Dr. T. R. Brown; A Case of Squamous-celled Epithelioma Probably Primary in the Thyroid Gland, by Dr. W. M. Lewis; The Relation of Appendicitis to Rheumatism, Report of Cases, by Dr. J. M. T. Finney and Dr. L. P. Hamburger.

Hospital Staff Changes.—Dr. L. Webster Fox, of Philadelphia, has been appointed a manager of the Orthopædic Hospital and Infirmary for Nervous Diseases at Philadelphia by Governor Stone, to fill the vacancy caused by the death of James B. Nicholson.—Governor Odell has appointed the following managers of the Middletown State Homeopathic Hospital: James B. Carson, Frederick W. Devor, Edward Tompkins, John W. Slauson and William K. Stansbury, reappointments; Edward F. Pierson, who failed to qualify, was reappointed.

The Chicago Baptist Hospital Loses the Estate of Mrs. Anna B. Duval by the verdict of a jury in a Chicago court on March 28th. Mrs. Duval had bequeathed all her estate to the hospital, where she was a patient at the time of her death. Her only child, Ernest Augusta Duval, of Brooklyn, N. Y., was cut off without any legacy. The three witnesses to the instrument were Isaac E. Roll, Mabel Clark, and Bridget Kelly. As they expressed their opinion that Mrs. Duval was not in her right mind at the time the will was drawn, the Probate Court refused to admit it to probate.

The Opening of the Charitable Annex of the Loomis Sanitarium.—The charitable annex in connection with the Loomis Sanitarium, at Liberty Heights, Sullivan county, New York, was opened on March 22d with twelve patients. The present capacity of this annex is twenty-four patients. The patients are charged five dollars a week, for which they receive their board, lodging, medical attendance, medicines, and laundry; they also derive all the benefits of the main sanitarium in the way of scientific care and oversight. The deficit between the five dollars a week charged to patients and the actual cost of maintenance is made up by a maintenance fund raised annually by subscription. While the financial affairs are administered from the main sanitarium, there is a superintendent in charge at the annex. Dr. J. Edward Stubbert, physician in charge at the main sanitarium, visits the annex once a week as consulting physician, while Dr. Stephen W. Wells, resident house physician, and Dr. Thomas I. Shannon, resident assistant house physician at the main sanitarium, constitute the regular visiting staff, making daily visits and keeping daily office hours at the annex. The nurses are furnished from the training school at the main sanitarium. This annex has a thoroughly equipped treatment room, and patients receive practically the same treatment that is given at the main sanitarium.

Births, Marriages, and Deaths.

Pith of Current Literature.

Married.

CLAIBORNE—CLAIBORNE.—In New Orleans, on Tuesday, April 16th, Dr. John Herbert Claiborne, Jr., of New York, and Miss Marie Louise Claiborne.

COOK—BARLOW.—In Wilmington, Delaware, on Tuesday, April 9th, Mr. Edward Glenn Cook and Dr. Drusilla G. Barlow.

CUTCALT—NEW.—In Baltimore, on Wednesday, April 10th, Dr. C. E. Cutcalt, of Fredericksburg, Maryland, and Miss Lydia New.

DAWSON—LEARNED.—In St. Louis, on Monday, April 8th, Dr. Percy M. Dawson, of Baltimore, and Miss Agnes W. Learned.

DAY—HARRIS.—In Rochester, on Tuesday, April 9th, Dr. Harry W. Day, of Cohocton, N. Y., and Miss Nellie L. Harris.

DODDS—LITTLE.—In Rochester, on Tuesday, April 9th, Dr. Seelye W. Little and Miss Mary Bellows Dodds.

HARDIN—SCOTT.—In Warrenton, Virginia, on Wednesday, April 10th, Dr. B. Lauriston Hardin, of Washington, and Miss Rosalie T. Scott.

HOPKINS—WOOD.—In New Market, Maryland, on Wednesday, April 10th, Dr. Howard H. Hopkins, Jr., and Miss Alice Eleanor Griffith Wood.

HOWARD—MCCLELLAN.—In Lakewood, N. J., on Tuesday, April 9th, Dr. Frederick Hollis Howard, of Philadelphia, and Miss Mary Mallevele McClellan.

LORD—STURGIS.—In Boston, on Monday, April 8th, Dr. Sidney Archer Lord and Miss Anne Outram Sturgis.

LOUDEN—MANSFIELD.—In Seaford, L. I., on Tuesday, April 9th, Dr. John T. Louden, of Amityville, L. I., and Miss Gertrude Florence Mansfield.

LOVE—SMITH.—In New York, on Wednesday, April 10th, Dr. Cornelius Ruxton Love and Miss Grace Anderson Smith.

MURPHY—STOREY.—In Onawa, Iowa, on Monday, April 8th, Dr. Francis J. Murphy, of Sioux City, Iowa, and Miss Mabel Storey.

NASON—MOSELY.—In Newburyport, Massachusetts, on Thursday, April 11th, Dr. Arthur Clark Nason and Miss Charlotte Augusta Mosely.

PELTON—SMITH.—In Newburgh, New York, on Wednesday, April 10th, Dr. Henry Hubbard Pelton, of New York, and Miss Nathalie Smith.

RAYMOND—CRAVEN.—In Philadelphia, on Tuesday, April 9th, Dr. Joseph Howard Raymond, of Brooklyn, and Miss Rachel Biddle Craven.

REESE—BENT.—In Baltimore, on Wednesday, April 10th, Dr. Charles Lee Reese, of New York, and Miss Harriet Stedman Bent.

SCOTT—MURRAY.—In New York, on Monday, April 15th, Dr. William Walter Scott and Miss Grace Edna Welch Murray.

SEXTON—HYDE.—In New York, on Wednesday, April 10th, Mr. William Lord Sexton and Miss Ida Josephine Hyde, daughter of Dr. Frederick E. Hyde.

SKILLIN—TUCK.—In New York, on Wednesday, April 10th, Mr. James Harper Skillin and Miss Rosamond Tuck, daughter of Dr. Henry Tuck.

TOMES—PURDY.—In New York, on Tuesday, April 9th, Mr. George H. Tomes and Miss Italia Inez Purdy, daughter of Dr. Charles G. Purdy.

WHARTON—SHIMER.—In Jamaica, L. I., on Tuesday, April 9th, Dr. J. Cambridge Wharton, of New York, and Miss Maud Cary Shimer.

WILSON—LOVELY.—In St. Paul, on Monday, April 15th, Dr. F. Leslie Wilson, of Walker, Minnesota, and Miss Ruth Lovely.

Died.

ABBOTT.—In Buffalo, on Tuesday, April 9th, Dr. Frank Wayland Abbott, in the fifty-ninth year of his age.

CHARLES.—In Kansas City, Missouri, on Tuesday, April 9th, Dr. J. W. Charles, in the sixty-eighth year of his age.

GURNEY.—In St. Paul, on Friday, April 5th, Dr. G. L. Gurney in the forty-seventh year of his age.

SUMMERALL.—In Kissimmee, Florida, Nellie Davis Summerall, wife of Dr. William B. Summerall, United States Army.

TUCKER.—In St. Paul, on Tuesday, April 9th, Dr. James M. Tucker, formerly of the United States Army, in the fifty-seventh year of his age.

Medical News, April 13, 1901.

The Immediate and Remote Results in One Hundred Conservative Operations on the Ovaries and Tubes, with Brief Reports of Four Cases. By Dr. W. L. Burrage.—The length of time consumed in the performance of conservative operations should be considered when operating on enfeebled patients, and the author's rule is to do nothing more than can be well done in two hours. Out of one hundred and fifty-six patients operated upon, three died as a result of operation. Symptomatic cure was recorded in seventy-three out of a hundred cases, and twenty-seven were not relieved after a year's observation. In regard to the probability of pregnancy occurring after conservative operation upon the ovaries and tubes, the author has found that nearly one-third become pregnant. In his opinion, the most unfavorable cases for conservative operations are the pronounced neurasthenics who are approaching the menopause; also patients with long-standing gonorrhœal infection, and those having both ovaries thoroughly riddled with cysts.

Tropacocaine Hydrochlorate—A Substitute for Cocaine Hydrochlorate in Spinal Anæsthesia. By Dr. Willy Meyer.—The main points in favor of tropacocaine hydrochloride as compared with cocaine hydrochloride are, that the former is less than half as toxic, while its depressing action upon the cardiac motor ganglia and on the cardiac muscle is much less, and recovery from its effects is much more rapid than is the case with cocaine hydrochloride. The author asserts, furthermore, that its solution is far more stable.

A Study of Cases Presenting Symptoms of Asthenopia and Anomalies of the Ocular Muscles in which Ablation of the Middle Turbinal was Effective Treatment. By Dr. Heber Nelson Hoople.

Acute Traumatic Malignancy. By Dr. William B. Coley.—The author reports seven interesting cases which lead to the conclusion that trauma is a very important factor in the causation of malignant tumors. He points out that this relationship between injury and malignant tumors furnishes additional, and by no means unimportant, evidence in support of the infectious origin of such tumors.

The Akouphone and its Limitations. By Dr. J. A. Kenefick.

Perforating Gunshot Wound of the Chest, with Fracture of both Bones of the Left Leg and Lacerated Wound of the Right Thigh. Recovery. By Dr. Victor Cox Pedersen.—This case is adduced as illustrating the value of the free use of sedatives in such conditions.

Medical Record, April 13, 1901.

Remarks on Enteroptosis. By Dr. Max Einhorn.—The author asserts that the corset is an important factor in the causation of enteroptosis, and he quotes from several authors to that effect. However, he also states that, in enteroptosis, some congenital anomalies are very frequently encountered. As to the frequency of enteroptosis, he quotes Glénard, who asserts that in female patients suffering from digestive disorders, about one in four is affected. It is much more frequent in women than in men. Though this condition may exist without any symptoms whatever, the patient often complains of a faint feeling or a certain weakness after rising. Frequently there is considerable fatigue after slight exer-

tion, such as walking, and in women this is often combined with pronounced backache. A feeling of weight in the lower half of the abdominal cavity is sometimes felt, while a dragging sensation is encountered in the epigastric region. Flatulence, constipation, and frequent micturition, are also met with. If this condition is kept in mind, it is not likely to escape detection. The prognosis is good. The treatment consists in the application of a well-fitting abdominal supporter, though ample nutrition is perhaps more important than the bandage. *More* than is absolutely necessary for the maintenance of the balance of the body should be eaten. Milk and bread and butter should be taken between meals. Outdoor sports are indicated. The value of massage is doubtful. All the digestive disturbances should be managed according to the general rules.

Small Hospitals and their Administration. By Dr. Louis N. Lanehart.—The author makes a strong plea for the rural hospital, and asserts that it is difficult to conceive of any community of moderate population where modern medical methods are dominant, in which a hospital is not needed. Little by little, such hospitals should come to be the educational centres from which emanate modern ideas of hygiene. That such rural hospitals should practically co-operate with their city neighbors is feasible and desirable, though the greatest good the rural hospital can accomplish is among its own community.

X-ray Photography. By Dr. Eugene R. Corson.—The author points out that the main thing in x-ray photography is an apparatus which generates powerful x-rays, and he asserts that mere spark length is no index of x-ray efficiency. In coil manufacture, after a certain length of spark has been obtained, every effort should be toward increasing the ampère, and a ten- or twelve-inch spark is quite enough, if the spark is a fat or a multiplied one, *i. e.*, has a relatively high ampère. Proximity of the bone to the photographic plate is very important, and care should be taken to prevent any movement even from the arterial pulsation.

Some Facts of Responsibility in Spirit and Drug Takers. By Dr. T. D. Crothers.—A large percentage of all medico-legal cases is associated with inebriety, and the legal responsibility of inebriates is decided from theories formulated centuries ago. The author points out that the question of responsibility is a question of facts—not theories. The influence of heredity, injuries, strains, and all the vast range of influences and forces which enter into the acts and character of every person, must be considered in the solution of the problem of responsibility. A new jurisprudence is demanded, and a new scientific study of, and recognition of the facts in, the cases of these inebriates and their disabilities are called for.

An Unusual Case of Partial Recovery from Embolism of the Arteria Centralis Retinæ. By Dr. Edgar S. Thomson.

Boston Medical and Surgical Journal, April 11, 1901.

A Review of the Literature of the Therapeutic Use of the X-rays. By Dr. Harvey P. Towle.—The author concludes: (1) That the real nature of the x-rays is not yet determined definitely, nor is it known whether the therapeutic action following their use is due to the action of the rays themselves or of something of electrical origin accompanying them; (2) that the treatment is not without danger unless the greatest care is used; (3) that the effects of the x-rays remain for a long time, and re-

covery is very slow; (4) that whatever may be the exact origin of the effects produced, a definite reaction is caused in the skin by the use of the x-rays; (5) that the changes induced in the skin are similar, histologically, to those seen in ordinary inflammation; (6) that the x-rays are not proved to have any bactericidal power; (7) that their therapeutic effect is probably due to the inflammation excited; (8) that hair can be removed by their use, and that lupus and several other diseases can be healed over; (9) that in a few reported cases we may fairly assume that a permanent cure has been effected, but that, in a majority of the reported cases, too little time has elapsed to rule out the possibility of a return of the disease; (10) that the effect of exposure to the x-rays is so extraordinarily slow in disappearing that months should elapse before an absolute cure is assumed; (11) that while the permanency of the cure effected may perhaps be doubtful as yet, it is certainly desirable to experiment further.

Pathology of the New-born as Illustrated in the Practice of the Writer. By Dr. Frederic W. Taylor.—The author, in a statistical article, gives his observations in six hundred and fifty-four obstetric cases. Ten per cent. were abnormal, either at birth, or during the first few days of life. All had been carried at least seven months. Twenty-three were still-born, twenty-two died within a few days, and in ten, respiration was delayed. There were three cases of mild ophthalmia, and two cases of melæna.

Oblique Subtrochanteric Osteotomy, for the Lengthening of the Femur, and Correction of the Deformity of Flexion Resulting from Hip-joint Disease. By Dr. E. G. Abbott.

A Case of Chin Left Posterior. By Dr. N. T. Swain.—This case is interesting as showing how easily a head well down in the pelvis, in a position rendering delivery impossible without violence, can be replaced above the brim; and, also, as showing the impossibility of the commonly accepted mechanism in this case, for while the head was so far down that it could advance no further without violence, the chin was not infringing upon anything.

Journal of the American Medical Association, April 13, 1901.

Reflections upon the Recent Status of Clinical Medicine. By Dr. Aloysius O. J. Kelly.—Inaugural address delivered at the opening of the session of the Medical Department of the University of Vermont.

The Present Status of Spinal Surgery. By Dr. Samuel Lloyd.—The author believes that it is unnecessary to say that no surgeon would undertake an operation of this magnitude where there was any chance of recovery by other means, but there still remains a considerable number of cases that occupy debatable ground, where the chances of recovery without operation are very slight, where continued mechanical treatment yields little or no result, and where an extension of the disease may render the patient hopeless if it does not destroy life. Such patients had better be operated on. Tables of seventy-nine cases of Pott's paraplegia accompany the article. (*To be continued.*)

Joint Tuberculosis. By Dr. De Forest Willard.—The author's injunctions are briefly summarized: 1. Diagnosticate early; treat early. 2. Do not look for positive inflammatory signs as indications of tuberculous invasion: the symptoms are entirely different, but are

equally positive, if a careful examination is made, muscular rigidity being one of the earliest and most reliable.

3. Discard entirely the existence of rheumatism of a single joint in children.

Permanent Catheterization. By Dr. J. Rilus Eastman.—The author believes that the danger of mechanical urethritis and cystitis as the result of the presence of a retention catheter, has been somewhat overestimated, and that after such a catheter has been in contact with the urethral mucosa for several days, there develops a distinct tolerance on the part of the urethra for the instrument, and that large catheters are rather to be chosen for permanent retention than smaller ones. A large catheter is much more easily retained than a small one.

Suggestions for the Reconstruction of Syphilitic Noses. By Dr. John B. Roberts.—The author gives a number of cases to demonstrate that the belief that syphilitic nasal deformity is incurable is an error. Aseptic methods, carefully planned and well-executed operations, and judicious after-treatment hold out the same hope of benefit as in other departments of surgery.

The Medical Treatment of Peptic Ulcer. By Dr. Frederick C. Shattuck.

Lavage of the Stomach as a Therapeutic Agent in the Treatment of Habitual Constipation. By Dr. C. D. Spivak.—The author states that a certain percentage of individuals suffering from habitual constipation are apt to have a spontaneous movement of the bowels the following day after the stomach has been washed for the first time, and the majority of such patients will eventually recover the normal functions of their bowels, if lavage is continued daily for two or three weeks, and later at greater intervals. The best results are obtained from the use of cold water or hot and cold water alternately, and the best time for such lavage is one hour before breakfast.

What Drug Standardization Means for the Physician. By A. R. L. Dohme, Ph. D.

A Visit to "Jesus Hilfe," or the Leprous Hospital at Jerusalem. By Dr. Jacob E. Schadle.

Conjugal Tuberculosis. A Study of Case-to-Case Infection. By Dr. H. M. Bannister.—The facts, as presented by the author, would seem to indicate a much greater risk, so far as personal danger of acquiring tuberculosis is concerned, from having a phthisical parent than from having a tuberculous husband or wife.

Keloid Following Traumatism. By Dr. W. M. Cole.—The constant application of flexible collodion is said to be of benefit in reducing the growth. The author advises complete excision, however, as the most rational treatment, provided that the flaps are properly coaptated, or, that the denuded surface is thoroughly covered with skin grafts.

Immunity against Zymotic Diseases. By Dr. William J. Class.—In districts where a certain zymotic disease is endemic the germs of this disease are comparatively widely distributed, though in a very much attenuated form. Epidemics are due to these germs becoming virulent, either by repeated passages through the animal body, or in some unknown manner. Immunity or insusceptibility to a given zymotic disease is usually acquired through the activity of the attenuated germ, which, although not capable of producing a typical attack, is still capable of producing an antitoxic body.

Yellow Fever and its Transmission. By Dr. Charles Finlay.

Some Technical Supplements in Complicated Enucleations. By Dr. W. F. Weymann.

Special Article—On the Plague in San Francisco.

Philadelphia Medical Journal, April 13, 1901.

Ligation of the Carotid Artery as an Operation Preliminary to Resection of the Superior Maxilla. By Dr. Carl Schlatter.—The author asserts that, by the application of a preliminary ligature, the hæmorrhage, as well as the danger from blood aspiration, is markedly diminished. This ligation is indicated in all anæmic individuals, and in those whose vitality has been lowered from cachexia and hæmorrhages, provided they do not suffer from diseases of the blood vessels, particularly arteriosclerosis. Exposing the bifurcation of the carotid in advanced cases is in itself indicated for the purpose of extirpating the lymphatic glands, which, in this region, are generally the first attacked by metastasis. In by far the majority of cases, ligation of the external carotid alone will suffice; the latter should be a permanent ligation. Conducted antiseptically, the procedure is without danger. The ligature can be applied by enlarging upward the incision which has been made for exposing the bifurcation. In exceptional cases it becomes imperative to ligate the common carotid, which, if done temporarily, seems to be less dangerous than a permanent ligation.

Thoughts on the Treatment of Diabetes Mellitus, being Part of a Clinical Lecture Delivered at the Philadelphia Hospital, March 13, 1901. By Dr. James Tyson.—The author suggests that our search for curative treatment should be directed, more than it has been in the past, to measures that aid oxidation. Any tendency to actual cure brought about by the withdrawal of carbohydrate food must be because a greater or less arrest of the glycogenic and glycolytic offices of the economy may lead to the restoration of function. This benefit may happen in the mildest cases only. The author commends the use of arsenic in *small doses*, long and uninterruptedly continued. The fact that arsenic increases the number of red blood discs and the quantity of hæmoglobin in them, and thus facilitates oxidation, explains its good effects. Iron is also good, but a drawback lies in its constipating effect. Massage, bathing, and exercise are of importance in the proper treatment of diabetes. The author explains the effect of codeine and other derivatives of opium, and the less settled effect of the petroleum products advocated by the French school, as being due to the influence upon the metabolism of glucose in the distant capillaries of the economy. In conclusion he says that, while the dietetic treatment will remain our chief resource for some time, for complete curative treatment we must look elsewhere.

The Medical Relations of the Prevailing Forms of Food Adulteration. By Dr. Henry Leffmann.—The author directs attention to some common misstatements and misapprehensions in regard to glucose, oleomargarin, baking powders, and other substances. He notes that the former influence in many States has secured laws forbidding the coloring of oleomargarin, while no restriction has been placed on coloring butter.

Ruptured Traumatic Aneurysm of the Femoral Artery Due to Gunshot Wound, with Report of a Case. By Dr. Wallace Neff.—From the literature, the author concludes that while traumatic aneurysm of the femoral artery due to gunshot is not uncommon, ligations are usually followed by gangrene and subsequent amputa-

tions, and it rarely happens that the limb is saved, as in this case it was, particularly when the aneurysm is of the ruptured variety. He concludes that while the very heavy mortality during the civil war was due in a measure to a lack of modern aseptic and antiseptic precautions, the chief difficulty was the non-establishment of collateral circulation, and even now, with a technique well-nigh perfect, the same danger exists.

Multiple Tumors of the Sciatic Nerve. By Dr. John B. Roberts.

Venous Angeioma of the Flexor Muscles of the Fingers. By Dr. John B. Roberts.

Diabetes Mellitus as a Cellular Fault. By Dr. Thomas C. Ely.—The author considers in detail five general reasons for regarding diabetes as a fault of cellular protoplasm: (1) A biologic reason; (2) an hereditary reason; (3) a reason by exclusion; (4) associate diseases; (5) a therapeutic reason.

Lancet, April 6, 1901.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. J. M. Bruce.—In the third and last of the Lettsoman lectures the author deals with the application of the facts considered in the two previous articles. A mitral presystolic murmur is never significant of a senile lesion. An aortic diastolic murmur, alone or along with an aortic systolic murmur, means something more than atheroma produced by gout, alcohol, tobacco, or cardiovascular disease of nervous origin. Aortic incompetence developed in later life is the result of syphilis or of acute or chronic valvular strain; many instances can, of course, be traced to juvenile endocarditis. Always a serious lesion, aortic incompetence due to syphilis is particularly grave, as being so frequently associated with coronary disease and consequent myocardial degeneration. A fully developed basic systolic murmur is a very common sign of atheroma of the aortic arch and valves and great vessels in association with gout, diabetes, corpulence, etc. It is also one of the physical signs of syphilitic and traumatic affections of the aorta. An ill-developed basic systolic murmur is not uncommon in alcoholism, chronic Bright's disease and nervous strain. A fully developed and audible systolic murmur in the mitral area (independently of leakage in cardiac failure) is usually due to early endocarditis of rheumatic or other origin. But in some instances it may be due to valvular atheroma. An accentuated ringing second sound in the aortic area is of great value in the diagnosis of arterial tension and atheroma. Slight reduplication of the first sound is common over senile hearts strained in youth, and hearts degenerated by alcoholism. The *bruit de galop*, or cantering rhythm of cardiac sounds, is practically pathognomonic of Bright's disease, and is one of the most valuable, because one of the most ominous, of physical signs. A normally sized heart, with irregularity, increased frequency, and a variable mitral systolic murmur, is characteristic of tobacco poisoning. A heart enlarged on both sides and acting irregularly without murmur is, apart from cardiac failure, suggestive of strain in early life. Cardiac symptoms taken individually are of less diagnostic value than signs. No symptom is pathognomonic. *Prognosis:* In tobacco heart the prognosis is always good, if the use of tobacco is stopped; the author has never seen serious damage done by tobacco alone in sound hearts. A much more unfavorable estimate is to be formed of the prospect of life in the alcoholic heart. It is almost impossible for

the patient to give up the use of alcohol, and the cardiac degeneration is complicated with cirrhosis, neuritis or dementia. Prognosis in gouty heart is very difficult. While patients of this class sometimes improve under treatment, and the atheroma is repaired by sclerosis, yet sudden death from angina is far from uncommon. Most unfavorable is the forecast in syphilitic lesions; cardiac failure, aneurysm, or angina, usually develops, and proves fatal. Strain of the heart for the first time after the age of forty years is not so grave as might be expected. In all these conditions the possibility of the intercurrent of acute disease must not be forgotten. In conclusion, the author briefly reviews the question of *treatment*, dwelling on the following points: Iodide of potassium should be given freely in syphilitic lesions; it is a specific remedy of great value. Do not be afraid to purge every morning if necessary. When the appetite flags and flatulence occurs, instead of slops calomel should be given, and light solids persevered with. Nocturnal restlessness and sleeplessness should be met by permission to spend the night in an easy chair. Acupuncture and drainage are often of the greatest service in senile cases with dropsy.

Sclerotic Hyperplasia of the Pharynx and Nasopharynx. By A. B. Kelly, M. B.—The author reports the case of a man, aged thirty-four years, presenting the following striking features: A greatly enlarged uvula concealing the posterior pharyngeal wall; a thick band descending in each half of the posterior wall of the pharynx, passing down to and overhanging the arytenoids; and a thickening of the roof and floor of the nasopharynx leading to a marked diminution of its lumen. The uvula was removed with a galvanocautery, and the morbid process was found to consist of a diffuse uniform thickening, proving to be a marked interstitial hyperplasia. No history or evidences of acquired or hereditary syphilis were obtained; there was no cicatricial contraction as in rhinoscleroma, and cultures failed to show the presence of the *Bacillus rhinoscleromæ*. The case shows that the pharynx and nasopharynx may be the seat of a sclerotic hyperplasia unconnected with syphilis, rhinoscleroma, or other known infective disease. A similar morbid process may manifest itself beneath the vocal cords as subglottic hypertrophic laryngitis. The condition resembles closely that seen in the hyperplastic variety of hereditary syphilis of the pharynx and nasopharynx.

On the Existence of Immunity after Enteric Fever. By B. A. Nicol, M. R. C. S.—The clinical experiences of the author have led him to doubt the existence of any immunity against the disease, following an attack of typhoid fever. He cites two cases which show that the supposed immunity produced by very severe attacks of typhoid fever was not sufficient to protect the patients for more than six months from a recurrence of their illnesses. The presence of the Widal reaction in the blood of a patient is no guarantee that immunity has been produced. Many of the soldiers in South Africa, who had received antityphoid inoculations, and whose blood showed the Widal reaction, contracted typhoid fever within a very few months.

The Pathology and Treatment of Rheumatoid Arthritis. By Dr. P. W. Latham.—The author reviews the present status of our knowledge of the pathology of rheumatoid arthritis, and holds that the joint troubles in the disease are due to spinal congestion or chronic myelitis chiefly affecting the ganglion cells of the anterior horns, but extending also, when the disease is associated with "glossy skin," to the ganglion cells in the posterior

horns. If this is the case, the natural inference would be that, in the earlier stages of the malady, the treatment should be directed to the abatement of this spinal congestion and that probably this can be most effectively done by cupping or blistering the spine. He cites two cases in which this plan of treatment was adopted and followed by great improvement. But when the disease is advanced, the ends of the bones enlarged and the cartilages destroyed, one cannot hope to restore these to their normal condition by any counterirritation. But even in chronic cases, where there are exacerbations of pain and swelling, the application of blisters to the spine is of use, and the author has seen these conditions very quickly alleviated thereby and the further extension of the disease arrested.

A Case in which a Large Pyloric Tumor Disappeared after Gastro-enterostomy. Post-mortem Examination Eleven Years after Operation. By F. B. Jessett, F. R. C. S.—The author reports the case of a woman, aged fifty-six years, in whom a tumor the size of a small cocoon completely occluding the pylorus and having all the naked-eye appearances of a carcinoma, disappeared after operation. A gastrojejunostomy was performed in 1890 with perfect success, and the patient remained well until 1900, when she died of apoplexy. At the necropsy the tumor was found to have disappeared, and the pylorus was patent, though somewhat constricted. There was also a constriction about the centre of the stomach, forming a typical hour-glass contraction, the pylorus opening just beyond the constriction. After the atrophy of the tumor, the food had evidently passed through the pylorus and duodenum as well as through the artificial opening.

The Influence Exerted by Air upon the Exhibition of Anæsthetics. By Dr. G. Flux.—Air governs the administration of anæsthetics; by it the patient is enabled to live while he inhales the anæsthetic, and by its instrumentality the dose of the anæsthetic is determined. No manner of administration that involves the curtailment of a patient's air-supply or that fails to direct the course traversed by the air on its way to a patient, can ensure either accuracy of execution or limitation of results. No patient can live long without air, nor can tolerate, without injury or discomfort, any deprivation of his natural air supply. It is the air which ultimately determines the amount of anæsthetic inhaled. The system of administering anæsthetics by means of the air, is simple, and has the advantage that it is equally applicable to all anæsthetics. It consists, not in attempting to control the output of vapor by varying the copiousness of the source of supply, but in regulating the amount of fresh air that is permitted to take up fresh anæsthetic vapor at each inspiration, this amount being, though definite in composition, variable in quantity at discretion, and it becomes added to the fresh air which completes the inspiratory volume. The author uses, when carrying out this system in its entirety, apparatus of his own devising—namely, an inhaler for chloroform, an open apparatus for nitrous oxide gas, a special form of stopcock for use with nitrous oxide or for use when employing Clover's ether inhaler, whether with or without gas.

Three Cases of Acute Ascending Paralysis. By Dr. T. A. Green.

British Medical Journal, April 6, 1901.

A Plea for a Pro-maternity Hospital. By Dr. J. W. Ballantyne.

On a Uterus which Contained One Hundred and Twenty Fibroids. By J. Bland Sutton, F. R. C. S.—

The author reports the case of a woman upon whom hysterectomy was performed for profuse bleeding due to fibroids. On opening the uterus four sessile fibroids were found projecting into the cavity of the uterus. The cut surfaces of the uterine wall were very thickly dotted with small rounded fibroids. Microscopical examination showed each of these to correspond in every way to the larger, fully developed fibroids. From a careful computation of the tumors in the various sections, this uterus, which scarcely exceeded the dimensions of a fist, contained one hundred and twenty fibroids.

Placenta Prævia. By Dr. R. P. R. Lyle.—For clinical purposes it is unnecessary to divide placenta prævia into more than two varieties—complete and incomplete. The prognosis as regards the mother depends (1) on the variety of placenta prævia, the complete form being more dangerous than the incomplete; (2) on the treatment adopted, any form of mechanical dilatation of the cervix or the rapid extraction of the child being extremely dangerous to the mother's life; (3) on the amount of interference; (4) on early treatment. The prognosis on behalf of the child depends (1) on the period of pregnancy; (2) on the amount of hæmorrhage; (3) on the rapidity of labor.

For purposes of treatment, most cases of placenta prævia may be divided into three classes as follows:

1. Incomplete placenta prævia, in which the first stage of labor is well advanced; rupture of the membranes and the application of a tight abdominal binder will usually be found sufficient. 2. Cases of complete or incomplete placenta prævia, in which the os uteri is sufficiently dilated to admit two fingers. In cases of complete or central placenta prævia the placenta is perforated with the fingers, version (if necessary) is performed, and a foot brought down, a tight abdominal binder is applied, and the subsequent delivery left to Nature, unless, of course, the continuance of hæmorrhage should necessitate slight traction on the foot. In incomplete cases; the membranes are ruptured instead of perforating the placenta. The advantages of version and bringing down a foot are: (a) it does away with the tampon and consequent danger of infection; (b) it allows early operation; (c) it arrests the hæmorrhage with great certainty; (d) it gives time for the patient to rally; (e) it gives time for labor pains to set in and for consequent natural dilatation of the cervix; and (f) there is less danger of *post-partum* hæmorrhage. 3. Cases of placenta prævia in which the os uteri is not sufficiently dilated to admit two fingers. Such cases are rare and should be converted into cases of the first or second class by plugging the vagina tightly with boiled cottonwool until labor has advanced sufficiently to dilate the cervix. During the ten years, 1889-99, 74 cases of placenta prævia were treated at the Rotunda Hospital, with only 4 maternal deaths. Of the 74 children, 28 lived.

A Case of Puerperal Infection Treated by Operation (Pryor's Method). By N. S. Fraser, M. B.—The author reports a case of puerperal fever occurring in a primipara; earlier on the day of confinement he had seen a case of appendicular inflammation perforating the abdominal wall in an old man. The labor was normal, but on the second day the patient had a rigor, the temperature rising to 105° F. The temperature continued elevated and a second rigor occurred two days later. The uterus was then curetted and irrigated with salt solution; a broad incision was made into Douglas's pouch, and enough twenty-per-cent. iodoform gauze applied to completely fill all parts posterior to the uterus, and the uterus

was packed with the same. The temperature remained elevated for two days, and then gradually fell to normal by the seventh day. Colon injections of salt solution were given every eight hours, as recommended by Dr. Pryor. The urine gave an iodine reaction within eight hours after the operation.

A Note on the Separation of the Placenta in the Third Stage of Labor. By Dr. J. D. Slight.—The author advances the theory that the separation of the placenta is due to a stretching of the placental site. This stretching is caused by contraction of the thick, muscular portion of the uterine wall, which contraction not only compresses the placenta, but drags upon its site. The placenta having been thus freed is next expelled, and in the process of expulsion the membranes are stripped from the walls of the uterus.

Case of Ectopic Gestation; Operation; Recovery. By H. H. L. Pateh, M. R. C. S.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. J. M. Bruce.—The third and concluding Lettsomian lecture. (See abstract of the *Lancet* for April 6, 1901, in this number of the *Journal*.)

The New Type of Scarlet Fever from a Public Health Point of View. By Dr. W. Robertson.

A Preliminary Note on the Use of Ox-Serum in Rectal Feeding. By O. F. F. Grunbaum.—The author records some of the results obtained in rectal feeding with ox-serum, glucose, and milk, with liquor pancreaticus. Two grains of chloretone were added to each ounce of serum, that drug being a sedative as well as an antiseptic. Serum does not give rise to offensive stools, such as often occur when egg-albumen is used; its proteid is readily absorbed by the mucous membrane of the large intestine, and it is inexpensive. By introducing 90 cubic centimetres every four hours, 540 cubic centimetres of serum is introduced in the twenty-four hours, containing 38 grammes of pure proteid. In no case did a rash appear, or any albuminuria or albumosuria.

The Value of Diphtheria Antitoxine in the Treatment of Membranous Non-diphtherial Tonsillitis. By J. N. d'Esterre.—The author reports the case of a woman, aged thirty-five years, who within six months had two attacks of amygdalitis, in which the tonsils were completely covered with a yellowish membrane-like deposit. Cultures showed the presence of streptococci alone. Fifteen hundred units of diphtheria antitoxine were injected each time, and its use was promptly followed by a fall in the temperature and rapid improvement of the patient.

Gazette hebdomadaire de médecine et de chirurgie, March 24, 1901.

Palmar Luxation of the Index Finger.—M. Alexis de Hinto reports the case of a young woman who fell while carrying a vase, the index finger being pushed back upon the palm by the edge of the vase. This is a very rare accident. Reduction is performed by strong traction upon the finger, pressure upon the proximal end of the first phalanx and finally flexion.

Intra-arachnoid Anæsthesia.—M. P. Reclus says that lumbar injection of cocaine for the purpose of surgical anæsthesia may fail because of a fault in the technics, the needle completely traversing the canal, or the eye of the needle not reaching it, or the needle becoming filled with blood. Again, analgesia may be incomplete or may not last sufficiently long to permit of an operation. He reports one case in this connection in which anæsthesia

failed to appear for one and a half hours after a correctly performed injection. The analgesia disappears sometimes in as short a space of time as eleven minutes, as happened to the author while performing an operation for hernia. Omitting consideration of the fleeting, disagreeable symptoms, M. Reclus records a case in which vomiting persisted for four days, another in which paresis of the anal sphincter lasted for seven days, another in which a paraplegia of the legs was found a month after the injection. Finally, he reports in his own experience and in that of a few others, eight deaths immediately following the subarachnoid injection, out of a total number of 2,000, a mortality of two fifths of one per cent. Ether, chloroform, and the local use of cocaine, show no such high mortality figures as this. M. Reclus concludes that the ordinary methods of anæsthesia cannot, at the present time, be replaced by the subarachnoid method, which is dangerous, obscure in its technic, and sometimes uncertain.

March 28, 1901.

A Case of Bulbar Tabes.—M. Debove reports such a case, giving the symptoms and the results of the physical examination in detail.

Lyon médical, March 24, 1901.

Prostatic Elements in the Urine of Patients with Bacterial Orchitis.—M. L. Hugounenq and M. J. Eraud conclude from thirty-four examinations that certain proteid substances allied to the mucins are found in the urine of men suffering from tuberculous or gonorrhœal orchitis. The polariscope shows a deviation which is not present in traumatic orchitis, in ordinary gonorrhœal urine without orchitic involvement, or in the urine of healthy women.

Idiomuscular Excitement in Tabetics.—M. F. Duplant says that while idiomuscular irritability in tabetics seems exaggerated, it is most frequently normal. Edema of the muscles is obtained more easily in them, however, than in healthy persons. The apparent exaggeration demonstrates the integrity of the muscles, as the reaction is not due to irritation of the cutaneous or muscular nerves. The hypotonic condition of the muscles which is constant in locomotor ataxia, makes the idiomuscular reaction appear to be greater than normal, although it is not.

Centralblatt für Chirurgie, March 30, 1901.

Radical Operation for Large Ventral Hernia.—Dr. Salistscheff operated on a large umbilical hernia successfully by dividing the rectus muscle and covering in the defect with it. For this purpose, the muscle was split and then divided perpendicularly. An excellent result in this and in a subsequent case.

Wiener klinische Wochenschrift, March 21, 1901.

Poisoning by Agaricus Aorminosus.—Dr. Hngo Goldman describes the symptoms of poisoning by this fungus as beginning four or five hours after ingestion with nausea, headache, pain in the abdomen, and a sense of impending danger. Vomiting follows at intervals, at first of food, then of bile, sometimes of a little blood. The thirst becomes intense. Tenesmus and diarrhœa of a high degree appear, and collapse finally comes on. Anuria is usual. The physical signs correspond with the symptoms. Tannin by the mouth and by the rectum is the best means of treatment, and saline infusions are indicated.

Arthritic Affections in Scarlatina.—Dr. Edmund Homa reports a number of cases in which swelling of one or more joints, followed by suppuration, appeared during the course of scarlet fever.

Primitive Sight Organs. By Dr. Theodor Beer.

Centralblatt für Gynäkologie, March 30, 1901.

What are Brow Presentations?—Dr. Arthur Mueller pleads for a revision of the nomenclature of foetal positions as a necessary precedent for the more thorough study of the more uncommon positions.

Klinisch-therapeutische Wochenschrift, March 31, 1901.

New Method of Treating Tuberculous Osteo-arthritis.—Dr. C. Trneczek treats fistulous opening of tuberculous nature in the neighborhood of joints with injections of the following solution:

R Sulphate of sodium.....	6.4 grains;
Chloride of sodium.....	73.8 “
Phosphate of sodium.....	2.25 “
Carbonate of sodium.....	3.15 “
Sulphate of potassium.....	6 “
Distilled water.....	100 “

This formula represents the normal amount of these salts in human serum. The injection is made through a cannula attached to a hypodermic syringe, the skin first being anointed with borated vaseline. After the injection is made, the part is covered over with cotton and a Priessnitz pack is applied. Rest is then enjoined. No disagreeable results have so far attended the treatment. (*To be continued.*)

On Multiple Neuritis. By Dr. Karl Gumpertz. (*Conclusion.*)

Riforma medica, February 22, 1901.

Bier's Injections in Sciatica. By Dr. Felice Palle. The author has used injections of a two-per-cent. cocaine solution by the intraspinal route, as has been suggested by Bier, in a case of sciatica. He concludes that this method is to be recommended as one easy of execution and satisfactory in its results. In speaking of the rise of temperature that has been noted in patients with sciatica who had received lumbar injections of cocaine, by Bier himself, by Manega, and by the author in the present case, he gives the various hypotheses that have been suggested as explanations of this febrile phenomenon: The mechanical and chemical irritation produced by the injected liquid upon the spinal meninges and upon the nerve matter in the cauda equina: the effusion of blood that inevitably occurs in the epidural space as the result of injury to the vascular network which is encountered between the periosteum of the vertebra and the dura; and, finally, the irritation of the spinal cord and brain produced by the cerebrospinal fluid, mixed with cocaine solution and the extravasated blood. It is improbable that infection introduced in the act of injection of cocaine is the cause of the fever, for the rise of temperature is very constant in spite of the greatest antiseptic and aseptic precautions. The author is in doubt as to whether the paralysis that sometimes follows lumbar cocainization is due to the influence of the cocaine or to local pressure caused by the fluid injected.

Gazzetta degli ospedali e delle cliniche, February 3, 1901.

Concerning the Treatment of Varicocele. By Dr. Giovanni Benassi.—The author discusses the various

methods of treating varicocele and describes more particularly a method recently introduced by Parona (*Poli-clinico, VI, fasc. 1*). Parona sought to combine those advantages of the two methods that gave the best results—namely, ligature of the veins, and resection of the scrotum—and to eliminate the disadvantages of each. His incision begins a little above the external abdominal ring and descends downward for five or six centimetres to the scrotum. After exposing the sheath of the cord and the inguinal ring, the testicle is drawn out, care being taken not to injure its envelopes. The testicle is then raised and the tunica vaginalis is incised at a point opposite to the epididymis, so that the testicle may be drawn forward through the incision. The tunica vaginalis is now drawn from below upward toward the ring, in such a manner that the aperture from which the testicle issues is brought close to the inguinal ring, and the cord with its enlarged veins is gathered in the portion of tunica thus turned up. The edges of the incision in the tunica are then sutured to the margins of the inguinal ring, taking care that the testicle has a natural position and that the cord is not twisted. Finally, the incisions are sutured. Although Parona reports good results, the great disadvantage of this method is that the testicle is thereby deprived of the tunica, and that certain serious lesions may follow in the testicular substance as the result of this denudation, as has been shown experimentally by Alessandri.

Resection of the Knee; the Use of Gussenbauer's Hooks. By Dr. A. Dandolo.

Idiopathic Epidemic Parotiditis. By Dr. Nicola Gallo.—The author observed during the year 1899 a small epidemic of idiopathic parotiditis, consisting of nine cases, in which transmission of infection was clearly established. He concludes from a study of these cases, as well as from a consideration of the literature of the subject, that parotiditis may be an infectious disease, but not one that can be inoculated—at least he has not succeeded in reproducing the disease by this means. The fact that the secretion of the parotid is not infectious in these cases does not exclude the possibility that the disease is a general infection (an exanthem) in which the parotiditis is due to the action of a toxine upon the parotid gland.

A Contribution to the Study of Epidemic Icterus. By Dr. Achille Franchini.—The author observed, during the year 1899, an epidemic of jaundice in the commune of San Leo. This disease affected with preference the poorer classes, the members of the same family, and persons between the ages of twenty and forty years. The epidemic has gradually subsided, until it is almost extinct at present. The number of cases observed by the author exceeded sixty. The symptoms resembled those of benign catarrhal jaundice. At first there was a marked sense of general malaise, pain and heaviness in the abdomen, more or less marked anorexia, nausea, and vomiting. Jaundice appeared after four or five days, and was accompanied by changes in the color of the fæces, urine, etc. The liver was slightly enlarged and tender, the spleen was almost always normal. Pruritus was rarely observed. Albumin was found in the urine in one fatal case. An urticarial rash appeared in another. The average duration of the disease was two or three weeks. This epidemic occurred in a mountainous region which was supplied by excellent water, thus contradicting the statement of Kelsch to the effect that epidemics of jaundice occur in marshy, low places with foul water supply. No

other infectious diseases occurred in connection with this epidemic. These cases must not be confounded with infectious icterus, as described by some authors, in which there are febrile symptoms and swelling of the spleen, and which are probably caused by the *Bacillus coli* or the bacillus of Eberth. The author's cases were due to an undetermined species of the *Bacillus icteroides*.

An Apparatus for Determining the Seat of a Urethritis and Urethrocystitis of Gonorrhœal Origin. By Dr. Ismaele Castracane.—The author calls attention to the inaccurate results which are obtained with the Thompson "two-glass" test and the Fenger "three-glass" test, and suggests the use of a special apparatus for the determination of the site of a gonorrhœal urethritis or urethrocystitis. This appliance consists of a glass tube, two centimetres in diameter, having a capacity of 300 cubic centimetres, bent at right angles into the shape of a U, each arm gradually decreasing in size. One end is widened to admit the stream of urine, and each arm bears a scale indicating the amount of urine which it holds. The apparatus is mounted upon an iron support.

When the patient urinates into this tube, the first portion of the urine voided enters the first arm, the second into the horizontal portion, and the last into the second arm. On introducing an aniline solution into any one of the three portions, and on filling the other parts of the tube with water, it was found that there was scarcely any intermixture between the three parts of the tube. The presence of turbidity in the first, second, or third portion of the tube indicates the location of the inflammation, according to the principles laid down by Thompson, Ultzmann, and Fenger. The advantages of the apparatus are, that there is no interruption in the act of micturition; that the urine is distributed in such a manner as to render examination and comparison easy, so that the slightest degree of turbidity may be detected; that the amount of sediment may be estimated by looking at the scale on the tube, and that this sediment may be easily withdrawn for further examination by means of a pipette.

Concerning the Treatment of certain Cases of Syphilis which Rebel against Mercury and the Iodides; Flushing the System with Artificial Serum, with or without the Addition of Solutions of Mercuric Bichloride. By Dr. Michele Gravagna.—The author has used injections of artificial serum, with or without the addition of bichloride, in two cases of refractory secondary syphilis. In the first case the patient was suffering from an unusually intense syphilitic infection, against which various mercurials, Zittmann's decoction, etc., were used without avail. Injections of large quantities of Hayem's fluid—so-called artificial serum—gave no better results, and the patient died of syphilitic cachexia. In the second case there were persistent lesions on the face which would not yield to ordinary specific treatment. No effects whatever were obtained from injections of Hayem's fluid, or from injections of Franceschini's solution of bichloride. The lesions disappeared when Zittmann's decoction was administered and when they were treated locally with an ointment containing calomel and zinc. The author concludes, so far as he may from two cases, that the new method of treatment is not to be relied upon. A similar conclusion was reached by Tomasoli in an article on this subject.

Return of Reason in the Pre-agonal Stage of Dementia. By Dr. Riccardo Albericci.—The author reports a case of senile dementia in which the patient's reason returned for a brief period just before death.

Vratch, February 24, 1901 (March 8, New Style).

Large Fœtuses. By Dr. B. N. Agafonoff.—The author reports a case of labor in which the child weighed 5,950 grammes and measured 58 centimetres in length. The other measurements were: *Circumferences of the head*—horizontal, 38 centimetres; oblique, 43.5 centimetres. *Diameters*—occipitofrontal, 12 centimetres; occipitobregmatic, 14 centimetres; suboccipitobregmatic, 10.5 centimetres; biparietal, 9.5 centimetres; bitemporal, 8 centimetres. *Circumference at shoulders*—49 centimetres; biacromial diameter, 18 centimetres. The measurements of the mother's pelvis were: Spines, 25 centimetres; crests, 29 centimetres; external conjugate, 22 centimetres; transverse, 35 centimetres. The head measurements thus exceeded but slightly those of an average infant at term. The head of this child was, in fact, small in proportion to its body, the diameters of the shoulders and buttocks being considerably larger than in the average newly-born child. This circumstance was the explanation of the comparatively easy descent of the head and the delay in the passage of the shoulders. The author was called after a midwife had delivered the head and no further progress could take place on account of the impacted shoulders. The child's face was black, and there were no signs of life when the physician arrived. The shoulders were delivered with a great deal of difficulty and the child was found to be dead. The placenta was very large and weighed 1,190 grammes. The mother was a middle-aged multipara, and both parents were of unusually large size. The largest "giant fœtus" on record was that reported by Blach (*Medical Record*, March 22, 1879, and December 29, 1883). This child weighed 12,000 grammes and the placenta weighed 5,000 grammes.

The Treatment of Tetanus. By Dr. M. I. Rostovtzeff.—The author reports two cases of tetanus which he treated in 1899. The older remedies should be administered as the symptoms require, even when Behring's antitoxine has been used. The local treatment of the site of infection is of great importance, as the tetanus bacilli cannot spread through the body, but send their toxins to the nerve centres from the primary infecting focus. The use of diuretics, diaphoretics, baths, and subcutaneous injections of normal salt solution, may also be of value in causing the elimination of the toxins. In the first case the author observed the phenomenon known as "local tetanus," which is rarely seen in man; the first signs of tetanus appeared in the affected limb. The explanation of this phenomenon is not yet clear. Four injections of Behring's serum were used and the patient recovered slowly from an attack of tetanus of average severity. In the second case, the author used injections of an emulsion of calf's and pig's brain. The patient recovered slowly, but remained in a condition of cachexia and muscular atrophy, so that she could scarcely walk. Kernig's sign was present in a marked degree during the convalescence, and the author says that the presence of this sign has never been noticed before in tetanus, probably because no attention has been paid to it. Its presence is probably due to the fact that the toxins of tetanus that accumulate in the spinal cord have an irritating influence upon the meninges, without actually causing an inflammation. The second case was more severe than the first. While it cannot be denied that the patient may have recovered without the injections of brain emulsion, the improvement after these injections was very well marked; the symptoms became stationary instead of

progressing, as they did before the injections, and the general condition improved.

Initial Stages of Heart Disease in Soldiers. By Dr. D. I. Vieriujsky.—The author calls attention to the fact that in the initial stages of organic heart lesions there may be no physical signs warranting the diagnosis of heart disease, and that, under unfavorable conditions of military life, a well-marked set of physical signs may appear during the third or fourth year of service. He has observed this occurrence in a number of cases. In a certain number of men who come before the examining physician of the military post there are no fully developed physical signs that speak of an organic lesion, and yet there may be enough to suspect that the heart is not perfectly normal. It is difficult to decide in many instances whether one has to deal with healthy heart, or with a latent heart disease. In 57 doubtful cases, 45 had been rejected as having heart disease; the rest were found to be cases of functional disturbances—neurasthenia, anæmia, etc., and the cardiac symptoms disappeared after a period of observation in the military hospital. Of the 45 men in whom heart lesions were found, 36 were recruits and 9 were privates with more or less service behind them. Of the 36 recruits, 29 were sent to the hospital for confirmation of the diagnosis, the rest for existing illness other than the heart trouble. Of the privates, two came to the hospital on account of heart symptoms, the rest for other illnesses, and the heart trouble in these was found accidentally. Of the 45 cases, 20 had well-marked physical signs, 17 imperfectly developed signs and 8 no other sign than a slight inconstant murmur at the apex. Mitral insufficiency was the diagnosis in 44 cases, and aortic stenosis in one case.

might have been substituted, and asked my patient how much she had paid for the prescription. The answer was that she had paid thirty cents for the prescription, which, in view of the fact that homatropine hydrobromate cannot be purchased at less than thirty cents a grain—in fact, can hardly be purchased at that price—seemed to verify my opinion.

Calling up the druggist who had dispensed the prescription, over the telephone, he insisted that he had dispensed exactly what I had prescribed, also verifying my prescription by reading it to me over the telephone.

About twenty drops of the solution remained over, which I sent to the analytical department of a very well known manufacturing chemist, and received the following report:

“The examination of the colorless liquid received the 1st inst. showed the following:

“Evaporated to dryness and subjected to Vitali’s test for atropine, a beautiful violet color is obtained, eventually disappearing, but capable of reproduction in the usual way. This reaction is considered as characteristic of atropine and its isomers. Homatropine with Vitali’s test gives a yellow color.

“Known solutions containing homatropine hydrobromate and cocaine hydrochlorate do not give the violet color, while known solutions of atropine sulphate and cocaine hydrochlorate do not give the violet color. Cocaine hydrochlorate solution alone does not give the violet color.”

It is now over three weeks since the drops have been used in the eyes of my patient, and they are only slowly regaining their power. Everything, except the statement of the druggist that he has not substituted, points to substitution as the cause of this long duration of the paralysis of accommodation. If substitution was practised, it is very likely that one grain of atropine was substituted for the one grain of homatropine prescribed, but that the rest of the prescription was not changed. If this is the case, then the patient had instilled into her eyes the evening before examination two drops in each eye of a solution of atropine of a strength of eight grains to the ounce, which was furthermore strengthened by the cocaine solution. The next day two drops were put in each eye six or seven times within two hours, enough to not only thoroughly paralyze, but possibly, also, tear some of the fibres of the ciliary body.

This substitution of atropine for homatropine is not at all so infrequent as it might appear, having occurred in my practice several times, once, as I remember, some years ago, in the case of a violinist, who was forced thereby to give up an engagement.

This letter is written for the purpose of drawing the attention of the profession to the fact that, if a substitution of atropine for homatropine is practised, the patient would be likely to get the atropine in larger doses than would be the case if atropine were directly prescribed. The patient, furthermore, would have the larger doses instilled in his eyes with greater frequency, in this way not only having as much paralysis of accommodation as is usual when we prescribe atropine, but a great deal more, and, in fact, a dangerous amount.

The patient may, furthermore, lose a great deal of time in consequence of the substitution, and if of advanced age may, in consequence of the increased intra-ocular tension which persists for a long time, become glaucomatous.

Lastly, the patient is likely to lose confidence in his oculist, who promised him a return to normal vision for the next day, whereas, in consequence of the substitu-

Letters to the Editor.

A FLAGRANT CASE OF SUBSTITUTION.

154 EAST THIRTIETH STREET,
NEW YORK, March 20, 1901.

To the Editor of the *New York Medical Journal*:

SIR: A few weeks ago I wrote the following prescription for one of my patients, a young lady fifteen years old, for the purpose of examining her eyes for an error of refraction:

R Homatropine hydrobromate. gr. 1;
Cocaine hydrochlorate. gr. i;
Aq. dest. dr. i.
M. D. S. Use as directed.

The directions, as given by me to the patient, were to put two drops of the solution in each eye in the evening before going to bed; then, the next morning, to put two drops in each eye every fifteen minutes, five times, starting one hour before leaving her residence for the purpose of coming to my office for examination, and to bring the drops along, so that I might put them in her eyes once or twice before examining her eyes. The young lady had the prescription compounded at a pharmacy, used the drops according to directions, and presented herself for examination at my office. I found the pupils fully dilated, put the drops once or twice in her eyes, and proceeded with the examination. This completed, I asked her to return to my office in two days, when the effect of the mydriatic would have entirely disappeared. When she returned, however, I found that the pupils were still widely dilated and accommodation was still paralyzed. I at once thought that atropine

tion, this return to normal vision may be deferred for weeks, even if no serious harm results.

A. W. HERZOG, M. D.

SECONDARY POST-PARTUM HÆMORRHAGE.

334 EAST SEVENTY-EIGHTH STREET,
NEW YORK, March 10, 1901.

To the Editor of the New York Medical Journal:

SIR: On the 25th of January, 1901, at 5 P. M., I attended, in confinement, a woman of evident good health, and she gave birth to a healthy girl. The placenta came away in a few minutes on my executing Credé's method, whole and sound. There were no after-pains. The patient spent twelve days in bed, having a normal pulse and temperature—in fact, in every way in fine physical condition. I saw her as often as possible during that period, and there were no signs of any fever, nor were the lochia decomposed. Certainly I had no cause to be suspicious of any foreign substance in the uterus. On the thirteenth day after her confinement, at 11 P. M., while passing urine, she filled a pot with blood. Being called in, I stopped the hæmorrhage by injecting hot water and packing the vagina with absorbent cotton. The patient slept comfortably that night and felt well the next day. Still keeping to her bed, she had a good appetite and showed no indications of further trouble. She passed the next night comfortably also, but at 6.30 A. M., upon her awakening, due to the cry of the baby, hæmorrhage occurred again, and pretty nearly filled a zinc douche-pan with blood. As a consequence the patient became extremely weak and heart failure threatened. Stopping the hæmorrhage again, at the same time I sought for its cause; but, on exploring the uterine cavity, I found no evidence of retained placenta or decidua, but intra-uterine hæmorrhage. On my curetting the uterus, the hæmorrhage ceased, and I packed the uterus partly, and the vaginal canal wholly, with iodoform gauze. There were no signs of inflammation either on the cervix or in the vagina, but the cervix was well dilated. Upon external palpation, the uterus was flabby and enlarged. I kept the patient in bed and treated the anæmia. The pulse was scarcely perceptible to the touch and there were signs of impending death, so that I gave up hope for the life of the patient. A colleague, who was called in, injected, hypodermically, a twelfth of a grain of strychnine, together with a twentieth of a grain of digitalin, taking no cognizance of previous injections of a thirtieth of a grain of strychnine and ten minims of ether, every five minutes for nearly two hours and a half, which failed to do the work. This seemingly lethal dose of strychnine, combined with digitalin, fortunately brought the pulse up, and after that the patient improved rapidly, and completely recovered in two weeks. Our first day's treatment was by rectal injections of normal salt solution every two hours. Ergot was given every two hours, and strychnine, hypodermically, a sixtieth of a grain, for the first six hours, and every two hours afterward by the mouth, together with champagne, milk, brandy, and cracked ice. Ice was applied to the pelvic region, and hot bottles were put to the feet. The use of ergot was discontinued the next day.

I make frequent visits to this patient, and find her in a good, healthy condition. The cause of the hæmorrhages is still a question to us. The diagnosis I made of this peculiar case was that of subinvolution, but if any gentleman of the profession will give a different diagnosis, I shall be glad to learn.

P. M. MILLER, M. D.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twenty-second Annual Congress, Held (in Conjunction with the Congress of American Physicians and Surgeons) in Washington, on Tuesday, Wednesday, and Thursday, May 1, 2, and 3, 1900.

The President, Dr. SAMUEL JOHNSTON, of Baltimore, in the Chair.

(Concluded from page 525.)

Supplementary Report on a Recurrent Tonsillar Tumor.—This was the title of a paper by Dr. R. P. LINCOLN, of New York (see Vol. lxxii, page 705).

The Correction of Deviations of the Nasal Sæptum, with Special Reference to the Use of Fenestrated Comminuting Forceps.—This was the subject of a paper by Dr. JOHN O. ROE, of Rochester, N. Y. (see page 624).

Dr. A. W. DE ROALDES, of New Orleans: I feel indebted to Dr. Roe for a clearer understanding of his method of correcting deviations of the nasal sæptum. There are still some points connected with the procedure which I should like explained—for instance, the exact location of the bony and cartilaginous hinge of which he speaks, whether it is vertical, and whether on this line of fracture hinges the whole anterior part of the deviated sæptum. If that is the case, I wish to say that Professor Moure, of Bordeaux, has lately adopted some similar procedure in what he will present shortly as a new method for the treatment of sæptal deviations. In a conversation with him a few months ago, and while he was questioning me on the methods of Dr. Roe and of Dr. Asch, he said he had procured the latter's instruments. Misconstruing the *modus operandi*, he had performed several operations in which, if I understood him well, he severed the sæptum in its whole thickness, along its attachment to the floor of the nose, from the columnar cartilage to the posterior chondro-osseous articulation, his next step being to incise the sæptum high up from the column, backward in a direction parallel to the external median line of the nose. He thus obtained a truncated conical cartilaginous partition which, when fractured at its posterior attachment, allowed a displacement *in toto* of the deviated sæptum, with the idea of obtaining union of the fracture in a modified direction, calculated to correct the deviation. Good results were thus obtained by Dr. Moure, who, having designed two instruments to facilitate his technique, was kind enough to present them to me.

Dr. JONATHAN WRIGHT, of Brooklyn: Dr. Roe has aroused so much admiration and, I must confess, a little despair in the minds of us all in describing the external deformities of the nose, that it is refreshing to be able to understand exactly what he means by operations upon the nasal sæptum. I have used with a great deal of benefit the form of forceps he has shown for breaking up the sæptum, but I have not used the form of cutting forceps which has been exhibited by Dr. Roe. In using one as large for breaking up the sæptum as the one which has been passed around, it would seem to me that we might dangerously fracture the whole sæptum. The small instrument is extremely useful for breaking up the cartilaginous portion of the sæptum. I have used the cutting forceps of Dr. Asch for making the incision, and have used the instruments of Dr. Roe for destroying the resiliency.

Dr. ROE: The blades inserted in the instrument passed around are longer than those commonly required

in the correction of sæptal deformities. Since I first described this set of instruments I have abandoned the use of the cutting forceps, and have substituted the knife to which I have called attention in my paper.

Dr. W. K. SIMPSON, of New York: In drawing attention to the cartilaginous sæptum, I should like to know whether this instrument will fracture the sæptum. My experience in using a blunt instrument, no matter how powerful it may be, is that you can bend the sæptum to any extent you desire, but it will immediately slip back again, so that our ability to fracture it is limited.

Dr. ROE: A good deal depends upon the thickness of the sæptum.

Dr. SIMPSON: How long do you leave the retention splint in?

Dr. ROE: From four to six days, until a provisional callus is thrown out sufficient to hold the sæptum rigid and maintain it permanently in place.

Dr. EMIL MAYER, of New York: I did not hear all of Dr. Roe's paper, but I gather from what has been said that his method consists in making an incision with the knife through the cartilaginous sæptum, a sort of saw-buck incision, and that by means of compression forceps he comminutes the parts and inserts a packing for several days, and then discharges the patient as well. I should like to ask whether he has observed any meningeal symptoms following this crushing and rolling motion? I say this because a great many operators fail to understand the Asch operation, and, instead of using compression forceps merely as compressors and nothing else, make the mistake of using a rocking and rolling motion, and, although I have not seen any cases recorded, I have heard indirectly of two fatalities as a result of this particular rocking and rolling motion. Dr. Roe says that the difference between the incision made with the knife and that made with the scissors is that he makes an X-incision, while in the other instance the incision is rectangular. If one will follow closely what has been written on the subject and the descriptions by Asch and myself, he will see that the incision made with scissors is as nearly at right angles as possible; yet in three hundred cases of my own I do not believe a single one of them has been a right-angle incision. They are the saw-buck incisions. Regarding tubes, it is merely a question of how long compression should be made, or how long they should be worn. Perhaps I am responsible for the length of time (five weeks) that the tube should remain *in situ*. It may be possible that I shall experience a change in heart like Dr. Roe and leave my patients without tubes at the end of the third week. In one instance, where there was a tendency to perforation, I took the tube out at once, which I always do if there are indications of sloughing at the junction of the incision. This patient did well with the tube used occasionally for a few days, and at the end of the third week I discarded the tube altogether. The length of time the tube should be kept *in situ* is purely arbitrary. Regarding the packing of Dr. Roe, his method is identically that described by Dr. Asch in his first paper presented to this association. It was discarded as being very annoying to the patient and offensive also, and the tubes were substituted.

One point should be clearly understood, namely, the anatomical configuration of the sæptum itself. If we make an incision through the sæptum from above downward, we find that the portion of it on a line with the columnar cartilage broadens out; that is the normal condition of the sæptum. It is narrower near the external portion of the nose, and broader as it comes toward the skull. We have to do undoubtedly with a cer-

tain amount of thickening and enchondrosis in all deviations, hence the need of care of that portion after the tube is withdrawn.

Dr. Roe has unquestionably improved his method of operating on the cartilaginous sæptum so far that it is almost impossible to tell the difference, except in the manner of using particular instruments, between his operation and the one described by Dr. Asch.

Dr. ROE: For fear the members may be misled by the remarks of Dr. Mayer, I would say that the incision of the sæptum is beveled and made at an angle, like this (indicating), about 45°, so that we have two edges sliding by each other like two wedges, whereas, if the cutting forceps is used, it is usually impossible to make a beveled cut. If the cut through the sæptum is made at right angles, and the ends are forced by each other, the cut surfaces do not come in contact at all, but the blunt edges override each other, affording no opportunity for union of any portion of such surfaces to take place. Dr. Mayer inquires if there are specific directions for making this incision. None, except that it is to be made through the most convex portion, whether the deviation or deflection is horizontal or oblique. If the deviation is a combination of the horizontal and oblique, frequently both a vertical and a horizontal incision should be made. If the line of convexity is oblique, you, of course, make the incision obliquely to correspond with the direction of the deflection.

Dr. MAYER: What is the length of the incision?

Dr. ROE: What is suited, in your judgment, to the requirements of the case. I have employed a modification of the operation which has been described in my external operations through the skin for many years, and have been surprised to find how slight the scars were after the operations. After the removal of tumors, sometimes the scars can hardly be seen after a few months. There is an advantage to be gained by having a beveled portion, in that it may become attached to the unbroken mucous membrane on the other side. I have not made a rectangular incision in these cases. If the instrument is inserted obliquely, we always have a beveled cut.

Dr. WILLIAM E. CASSELBERRY, of Chicago: I have used both the Asch scissors and a scalpel in making the incisions for deflection of the cartilaginous sæptum. Under general anæsthesia, the scissors seem to me more precise, especially for the second incision, when hæmorrhage is free. With cocaine anæsthesia only, a scalpel is best, because it is less bulky, permitting a view of the parts incised and greater delicacy of manipulation. To operate with cocaine anæsthesia requires a patient of reasonable self-possession and fortitude, but then it is entirely feasible and presents certain advantages as regards vision, position of the patient, and the control of hæmorrhage. I have used a double-edged scalpel with a sharp but rounded instead of pointed end. It is a convenient instrument with which to practise Roe's limited incisions—that is, cuts which pass through the mucoperichondrium of one side and the cartilage, but not through the mucoperichondrium of the other side, which in certain cases of moderate bulging deflection is an improvement on the Asch incisions, for the reason that there is less liability to permanent perforation after them. With the finger in the concave nostril, one can feel such a rounded scalpel pass through the cartilage and approach the mucoperichondrium without cutting the latter and without injuring one's finger. If the bulge is extreme or the deflections angular, I have not considered these limited incisions fully adequate.

I was particularly pleased to hear the percentages

given by Dr. Roe of cases in which the osseous portion of the *sæptum* was involved. I have heard Dr. Asch insist that his operation was intended only for cartilaginous deviations, and not for osseous deviations, and that he objected to fracturing the osseous portion of the *sæptum* as unsafe, particularly when the rolling motion of the forceps was used. My experience agrees with that of Dr. Roe as regards the large percentage of cases in which the bony parts are involved, and as to its being necessary to correct in some manner the bony deflection in order to secure a satisfactory result. I have used the forceps of Dr. Roe for compression of the *sæptum*, the smaller sizes being best adapted to the form of compression which he has so well described, in which the rolling motion is not used.

I should like to ask Dr. Mayer, who in a measure represents Dr. Asch, why it is necessary to make the arms of the crucial incision vertical and anteroposterior, or why it is not adequate to make both incisions slanting—that is, a saw-buck incision? I have found it difficult with the Asch forceps to make the incision exactly up and down, my incisions usually slanting more or less like a saw-buck. I should also like to ask Dr. Mayer whether he has seen any severe hæmorrhages in those cases in which he has used the tube immediately after the operation. I understand that he puts in a vulcanite tube at once, puts the patient to bed, applies ice-water cloths across the nose, and sprays with an iced alkaline solution. Having observed hæmorrhages in both ambulatory and hospital cases, I have preferred to pack both nostrils with antiseptic gauze as a first dressing, and introduce the tubes only at the end of from two to four days. I believe this precaution to be especially advisable in ambulatory cases.

Dr. J. SOLIS-COHEN, of Philadelphia: When I am called in to perform the Asch operation, I rarely leave the tubes in more than six or seven days. I use tubes with perforations for the purpose of allowing any granulations to get through and hold the tube tight in place.

Dr. SIMPSON: In connection with the good result of the Asch operation, I have found another objection in addition to those that have been mentioned, and that is, where we need retention splints, we are sometimes unable to get the tubes on the floor of the nose, and my experience in a number of cases is that, when we come to remove a tube that we have inserted, we find the bottom part of it has made a new shelf for itself, which will necessitate removal subsequently. One of the conditions of success in the Asch operation is that the splint should be applied well down on to the floor of the nose, so as to avoid the secondary shelf to which I have referred.

Dr. MAYER: I shall be pleased to answer the questions that have been asked, because I think they are part and parcel of this question, and because I believe the new method Dr. Roe has demonstrated is practically the same, with some slight modifications, as has been referred to in the discussion. As regards the point mentioned by Dr. Simpson, which he referred to a moment ago, there may be an anatomical condition of the *sæptum* which will absolutely prevent the tube from resting positively upon the floor of the nose. With reference to the question of packing and of hæmorrhage, and in reply to Dr. Casselberry, I wish to say that I look upon these operations as operations of magnitude; I think that an anæsthetic is requisite, and that the patients should not be allowed to go out after the operation has been performed, but rather they should go to bed for at least three days. This point has been brought out very clearly in an in-

teresting paper by Dr. Holmes, of Cincinnati, in which he reports over a thousand turbinotomies, without a single bleeding. He did not use the suprarenal extract, and he used no packing, but simply kept his patients in bed. In two hundred cases I have reported upon, which number includes those of Dr. Asch, Dr. Simpson, and myself, as well as some other surgeons in New York, in no single instance have we had to pack for hæmorrhage.

Dr. CASSELBERRY: I believe there have been two cases of severe hæmorrhage in patients that were put to bed.

Dr. MAYER: It is simply beyond my experience, and I cannot explain it except on the ground of some unusually placed blood-vessels or hæmophilia.

I wish to correct a mistake that has been made with reference to the Adams forceps as being in any way similar to Asch's. I am very sorry I did not bring one with me, but it is like the old-fashioned nut-cracker, which simply opens and shuts like a pair of scissors.

As to the percentage of cases of deviation of the cartilaginous *sæptum*, it is not so great as it would seem to be. A large percentage of bony deviations require no interference whatever, and what we call the absolutely normal skull is comparatively rare.

As to why the incisions are crucial, I would say that it is just as Dr. Roe has stated, that in this particular form of operation it is a fundamental principle to make a crucial incision, for with it we make four segments whose bases are broken, so that we destroy the arch and in that way straighten the nose by making the four segments override each other.

Dr. CASSELBERRY: The question was not why the incisions were crucial, but why one arm crossed up and down directly and the other arm anteroposteriorly. In the Asch operation one arm must be vertical and the other arm horizontal.

Dr. MAYER: You cannot make a crucial incision unless you take these two directions (illustrating). You have to make the incision in accordance with the direction of the deviation.

I am aware that I am trespassing on time, but, at the risk of being a little tedious, I wish to say that much confusion has been caused by Asch himself in the presentation of the bent scissors. I think ninety-nine deviations of the cartilaginous *sæptum* out of a hundred can be corrected without using that instrument, and it is here that the confusion has occurred. You really need a right and a left knife with the bent scissors, and then it is applicable to only a few cases. These scissors were devised for our own use where we had so many different forms of deviations to contend with, and oftentimes the deviation was so low down on the floor of the nose that we were obliged to make the incision low down and anteriorly. As a matter of fact, the equipment of any rhinologist would be perfect without these bent scissors of Dr. Asch's, and a straight scissors can be used in practically every case.

So far as the question of perforation is concerned, we must admit the possibility of it in every case, and the secret of not having perforation occur is in carefully watching the case, removing the tube on its slightest indication, seeing the patient daily, cleansing the nose one's self, and using nosophen or some such stimulant until all is healed, when the tube is replaced.

Dr. ROE: I am glad that Dr. Casselberry agrees with me in regard to the percentage of deviations in different portions of the *sæptum*. Deviations of the cartilaginous portions of the *sæptum* alone occur only in about

twenty-five per cent. of the cases, while nearly all other deviations are of a combined character, namely, of the osteocartilaginous portion of the sæptum. Therefore, the method which will properly correct the deviation must be one that is especially adapted to that form of deviation.

In regard to the observation of Dr. Mayer with reference to the Adams forceps, I do not see wherein the Asch forceps differs in principle materially from the Adams instrument. They both have perfectly flat blades, and in the use of either instrument for breaking the osseous portion of the sæptum it is necessary to twist or use a rotary motion, the danger of which is well recognized. By the method I have described, in which a fenestrated forceps is employed, no ringing or rotary motion is required, and no disturbance of any portion of the sæptum not included in the forceps is caused, because we have two supports on one side to counteract the pressure on the opposite side.

In regard to incising the cartilaginous portion of the sæptum, I am glad to know that Dr. Solis-Cohen has also found the slanting incision of special service. In many cases the incision can be carried through the cartilage only, leaving the perichondrium and mucous membrane on the opposite side intact. When the sæptum is thick, the perichondrium can at the same time be raised for a distance to allow the border of the opposite edge to slide under. In moderate bends of the sæptum this is unnecessary, but where the bend is large it is often of special service.

In regard to packing the nostril or supporting the sæptum, it is necessary to insert the dressing on the convex side only. Incision of the cartilage is, however, mainly required, as I have pointed out in my paper, where the deflection is confined to the cartilaginous portion of the sæptum, but when it is located in the osteo-cartilaginous portion the fenestrated forceps will usually bring the whole sæptum to the median line.

I have found the most efficient form of support to be a piece of aluminum wound with gauze, sufficiently large to fill the nostril and to force the sæptum over to the desired position. If the nostril and the dressing are made thoroughly aseptic, it can usually be left *in situ* for three or four days. It is then removed, the parts are thoroughly cleansed, and another one is introduced. This is left in place for two or three days longer. The sæptum is then carefully watched for a few hours to see if it is self-supporting. If ossification has taken place in the fractured bone, no further support is required. If there is a tendency to a return of the deviation when ossification has taken place, it is an indication that the elasticity of the sæptum has not been entirely overcome and that the operation has not been properly done.

My experience with the use of vulcanized rubber tubes for holding the sæptum in place has not been at all satisfactory, but I have used the dressings which I have described with great satisfaction, have never seen any hæmorrhage, and have observed no perforations of the sæptum to result from their use.

From the use of the fenestrated forceps I have had only the best results, and in no case has there followed cerebral disturbance of any kind, which I am sure might have taken place in many cases had I used the Adams forceps and broken the osseous portion of the sæptum as freely as I have done in a large number of cases by the method which I have described.

The Surgery of the Turbinal Bodies, with a New Method of Operating.—Dr. J. E. BOYLAN, of Cincinnati, read a paper on this subject (see page 415).

Dr. CASSELBERRY: I feel that the present reaction against the galvanocautery which found expression in a recent discussion before the New York Academy of Medicine, and which the essayist voices to some degree, is unjust toward that remedy. I have no doubt galvanocauterization is greatly abused, and that it is often inadequately or too extensively applied, but, skilfully used in suitable cases, I still find it beneficial and harmless, and I should be at a loss often to substitute other means for it.

Dr. MAYER: Just a word or two in reference to this subject. In cases where there is much hypertrophic tissue to remove, I would call your attention to the linear incision that has been suggested, making the incision first along the floor up into the body of the inferior turbinate, then turning to the right with the knife and coming right down to the bone, making a bone scar.

Dr. BOYLAN: In excessive hypertrophy or partial hypertrophy?

Dr. MAYER: In cases where there is enough tissue to warrant a thorough operation.

Dr. BOYLAN: I should like to ask Dr. Casselberry whether he has seen septic symptoms in any of his cases from the use of the cautery in the region of the middle turbinated body.

Dr. CASSELBERRY: I have many times made a linear cauterization along the anterior inferior aspect of the middle turbinated body, and never seen sepsis resulting. But cauterization of this structure should be limited to the baggy hypertrophy which is often found at this spot.

Dr. BOYLAN: As regards the reduction of hypertrophy by linear incision referred to by Dr. Mayer, I would say that my paper advocates turbinotomy in the advanced and indurated or myxomatous forms which are so frequently permanently associated with interference of the respiratory functions. Soft, or partial, hypertrophy is best treated by other methods, and in such cases I find a linear incision most efficacious.

As regards the use of the galvanocautery in hypertrophy of the turbinated tissue, so warmly advocated by the last speaker, when judiciously used in proper cases, it is a very excellent method; I use it frequently myself, as, for example, in the reduction of partial hypertrophy by deep incision, the destruction of minute polypi and myxomatous tissue, etc. But in the extensive and advanced hypertrophy referred to I cannot conceive of the burning away of a large surface of tissue as a scientific or even justifiable procedure, where we are able to remove by ablation the most diseased and offending part without injuring the remaining tissue.

Angeioma Cysticum of the Nose.—Dr. HENRY L. WAGNER presented a paper on this subject (see page 458).

Hæmorrhage from a Circumtonsillar Abscess.—This was the title of a paper by Dr. WALTER F. CHAPPELL, of New York (see page 371).

Dr. J. E. LOGAN, of Kansas City: I desire to say a few words in connection with this paper. I recall a case of double quinsy which once came under my care. The patient had never had rheumatism, and after he was relieved of quinsy I proceeded to operate upon him for deviation of the nasal sæptum, and I was struck very forcibly with the profuse hæmorrhage that occurred, and which came near resulting fatally. In a few days the patient was attacked with purpura hæmorrhagica after the

quinsy had subsided, and small spots developed on the legs. In tamponing the nose it required the closest application and attention to prevent the patient from bleeding to death. After the operation upon the nose he was put under the care of a general practitioner, was relieved of his trouble, and is living to-day.

Dr. MACKENZIE related a case of circumtonsillar abscess in which the bleeding point defied detection, but was finally located by means of a probe, which went into a pocket, evidently the interior of a wounded vein. After exhausting other methods of treatment, the vein was finally ligated and the hæmorrhage stopped.

The case was one of interest and brings out one or two points, the first of which is, that in cases of hæmorrhage about the throat, such as I have described, always carefully explore with a probe to see whether there is any pocket in the circumtonsillar region which represents, perhaps, a wounded vein.

We may sometimes have an anomalous large vein in this region which, when wounded by the knife of the surgeon, may give rise, if not discovered, to a fatal hæmorrhage. If the source of the hæmorrhage is not found, the patient may go on and bleed indefinitely. The second point is that, if plugging of the vein and obstructing the current do not suffice to arrest the hæmorrhage, no time should be lost in cutting down and ligating the wounded vessel.

Book Notices.

Die Entwicklung der inneren Medizin mit Hygiene und Bakteriologie im 19. Jahrhundert. Von B. NAUNYN, Strassburg i. Els. Centennialvortrag in der allgemeinen Sitzung der 72. Naturforscher-Versammlung in Aachen am 17. September, 1900. Pp. 21. Jena: Gustav Fischer, 1900.

Die Entwicklung der Biologie im 19. Jahrhundert. Vortrag auf der Versammlung deutscher Naturforscher zu Aachen am 17. September, 1900. Gehalten von OSCAR HERTWIG, Direktor des anatomisch-biologischen Instituts der Berliner Universität. Pp. 31. Jena: Gustav Fischer, 1900.

Die pathologische Anatomie im 19. Jahrhundert und ihr Einfluss auf der äussere Medizin. Von Professor H. CHIARI in Prag. Pp. 16. Jena: Gustav Fischer, 1900.

THESE addresses are in the nature of a review of the work of the past century in medicine, biology, and pathological anatomy, by the eminent authorities whose names appear as their authors. Professor Chiari's address is especially striking, showing the influence which pathology has had upon the development of internal medicine. The addresses of Professor Naunyn and Professor Hertwig are impressive in pointing out the wonderful advances which medicine and biology have made in the century just closed. The latter traces the development of the study of the cell of the ideas of ontogeny and phylogeny, and of the growth of the acceptance of evolution, in a most charming essay. All the addresses will well repay reading, and, Chiari's especially, thoughtful study.

Modern Medicine. By JULIUS L. SALINGER, M. D., Demonstrator of Clinical Medicine, Jefferson Medical College, etc., etc., and FREDERICK J. KALTEYER, M. D., Assistant Demonstrator of Clinical Medicine, Jefferson Medical College, Hæmatologist to the Jef-

erson Medical College Hospital, etc., etc. Illustrated. Philadelphia and London: W. B. Saunders & Company, 1900.

THE authors have here attempted a most laudable purpose. They have taken all the facts of physical diagnosis, of symptomatology, and of chemical and microscopic methods, and have placed them in one volume, so that the student or practitioner who wishes to elicit a Widal reaction, for instance, will not find it necessary to consult two or three text-books for the necessary data. In order not to make the volume too bulky, however, the authors have been compelled to condense their material, so that in some places they lose in clearness, as, again, in the discussion of the Widal reaction. We believe that, if more space had been devoted to the diagnostic methods and less to the symptomatology of disease, the reader of the book would be the gainer. And, yet, this is only a minor criticism, for the work is one of unquestioned value and embraces within its covers the generally accepted theories of diagnosis, pathology, and treatment.

The style of the authors is good, condensation is not so great as to impair clearness, and the facts narrated are those which modern medical thought indorses. The book is well illustrated, and some of the illustrations are original.

Manual of Pathology, including Bacteriology, the Technique of Post-mortems, and Methods of Pathologic Research. By W. M. LATE COPLIN, M. D., Professor of Pathology and Bacteriology, Jefferson Medical College, Philadelphia, etc. Third Edition, Revised and Enlarged. With Three Hundred and Thirty Illustrations and Seven Colored Plates, many of which are Original. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$3.50.]

THE three years which have elapsed since the second edition of Dr. Coplin's *Pathology* have exhausted the edition and compelled the publication of a new one. Advantage has been taken of this fact to thoroughly revise it. Colored plates are found for the first time, new illustrations have been introduced, and many of the chapters have been entirely rewritten. Dr. H. F. Harris has revised the chapters on neuropathology, which embrace the most modern views and methods of technics. The same must be said of the chapter on post-mortem examinations, which is especially good.

The new edition of this work can tend only to make it even more useful than it was before; for it is a well-balanced, complete, and thoroughly modern work.

A Text-book of Pathology. By ALFRED STENGEL, M. D., Professor of Clinical Medicine in the University of Pennsylvania, etc., with 372 Illustrations. Third Edition, Revised. Philadelphia and London: W. B. Saunders & Company, 1900.

THE third edition of Dr. Stengel's *Pathology* does not differ widely from the second edition. The book is somewhat larger, and the sections on neuropathology (by Dr. Joseph Sailer) and on pathological physiology have been extended. The same excellent qualities of thoroughness, clearness, and logic stand out distinctly as they did in former editions. It is no small tribute to a work of this kind that in less than three years as many editions of it have appeared. It is a thoroughly good work on pathology and its technics.

Pathology and Morbid Anatomy. By T. HENRY GREEN, M. D., F. R. C. P., Physician and Special Lecturer

on Clinical Medicine at Charing Cross Hospital, etc. Revised and Enlarged by H. MONTAGUE MURRAY, M. D., F. R. C. P., Lecturer on Pathology and Morbid Anatomy at Charing Cross Hospital. Ninth American Revised from the Ninth English Edition by WALTON MARTIN, Ph. B., M. D., Assistant Demonstrator of Anatomy, College of Physicians and Surgeons, Columbia University, etc. With 4 Colored Plates and 339 Illustrations. Pp. 2-17 to 585. Philadelphia and New York: Lea Brothers & Company, 1900.

WE have previously referred to this work as one which has long been a favorite here and in England. The new edition, which we find largely amplified, will not detract from its popularity. New chapters have been added on malaria and on the diseases of the blood, and these are fully modern and are excellently illustrated. The chapter on microscopic technics might be extended to advantage, we think, and directions for post-mortem examinations would not be out of place. Yet the work stands as a worthy exposition of the present-day knowledge of pathology and its processes.

A Compend of Diseases of the Skin. By JAY F. SCHAMBERG, A. B., M. D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine, etc. Second Edition, Revised and Enlarged. With 105 Illustrations. Pp. xv-9 to 291. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, 80 cents.]

QUIZ-COMPENDS are numerous these days, but not many of them pass into a second edition within two years, as this one has. It speaks well for the author that he has been able to impress upon teachers the value of his work, which contains much that is original, especially in the way of photographs.

BOOKS, ETC., RECEIVED.

A Handbook of Materia Medica, Pharmacy, and Therapeutics. Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription Writing. By Samuel O. L. Potter, A. M., M. D., M. R. C. P. Lond., formerly Professor of the Principles and Practice of Medicine in the Cooper Medical College of San Francisco, etc. Eighth Edition, Revised and Enlarged. Pp. xiii-17 to 950. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$5.]

A System of Practical Therapeutics. Edited by Hobart Amory Hare, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Second Edition, Revised and largely Rewritten. Volume III. With Illustrations. Pp. 3 to 841. Philadelphia and New York: Lea Brothers & Company, 1901.

Introduction to the Differential Diagnosis of the Separate Forms of Gallstone Disease. Based upon his own experience gained in Four Hundred and Thirty-three Laparotomies for Gallstones by Professor Hans Kehr, Halberstadt. Authorized Translation by William Wotkins Seymour, A. B. Yale, M. D. Harvard, formerly Professor of Gynecology in the University of Vermont, etc. With an Introduction by Professor Kehr. Pp. xv-17 to 370. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$2.50.]

Lectures on Nasal Obstruction. By A. Marmaduke Sheild, M. B. (Camb.), F. R. C. S. (Eng.), Surgeon to St. George's Hospital, London, etc. With One Colored

Plate and Twenty-seven Illustrations in the Text. Pp. x-106. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$1.50.]

Laryngeal Phthisis or Consumption of the Throat. By Richard Lake, F. R. C. S., Surgeon Laryngologist, North London Hospital for Consumption, etc. With Thirty-six Illustrations, Twenty-one of which are Colored. Pp. 94. Philadelphia: P. Blakiston's Son & Company, 1901.

A Compend of Human Physiology, especially Adapted for the Use of Medical Students. By Albert P. Brubaker, A. M., M. D., Adjunct Professor of Physiology and Hygiene in the Jefferson Medical College of Philadelphia, etc. Tenth Edition, Revised and Enlarged. With Illustrations and a Table of Physiologic Contents. Pp. viii-9 to 270. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, 80 cents.]

Memoranda on Poisons. By Thomas Hawkes Tanner, M. D., F. L. S. Eighth Revised Edition. By Henry Leffmann, A. M., M. D., Professor of Chemistry in the Woman's Medical College of Pennsylvania, etc. Pp. 5 to 175. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, 75 cents.]

The Medical News Pocket Formulary for 1901. By E. Quin Thornton, M. D., Demonstrator of Therapeutics, Pharmacy, and Materia Medica in the Jefferson Medical College, Philadelphia. Third Edition, Revised and Enlarged. Philadelphia and New York: Lea Brothers & Company, 1901.

The International Medical Annual: A Yearbook of Treatment and Practitioner's Index. Nineteenth Year. Pp. 682. New York: E. B. Treat & Company, 1901. [Price, \$3.]

A Text-book of Gynecology. Edited by Charles A. L. Reed, A. M., M. D., Gynecologist and Clinical Lecturer on Surgical Diseases of Women at the Cincinnati Hospital, etc. Illustrated by R. J. Hopkins. Pp. xxv-900. New York: D. Appleton & Company, 1901.

Nursing Ethics: For Hospital and Private Use. By Isabel Hampton Robb, Late Superintendent of Nurses and Principal of the Training School for Nurses, Johns Hopkins Hospital, Baltimore, etc. Pp. 9 to 273. Cleveland: J. B. Savage, 1901.

Miscellany.

Masturbational Neuroses.—*Love's Medical Mirror* for March gives an abstract of a paper on this subject read by Dr. William C. Krauss at a recent meeting of the Medical Society of the State of New York, in which it is stated that the writer has called attention to the fact that, of late, the habit of masturbation has been defended and partially encouraged by medical men and others, and to offset this teaching by showing the difficulty in treating such patients for nervous diseases was the essence of the paper. The acme of physical and mental activity has fallen from the fortieth to fiftieth year to the thirtieth to fortieth year, and anything that taxes the growing youth saps just that much mental and physical strength. It must not be surmised that every lad, once addicted to this habit, is a confirmed neurotic, for boys healthily constituted in body, mind, and morals do not tend to come under its influence to any very hurtful extent. The author warns against giving a favorable prognosis in cases of functional nervous disease with an underlying history of masturbation coupled with a neu-

rotic family history. The length of time in which these diseases generally are brought to a successful termination, if at all, will be greatly prolonged. Patients giving no history of masturbation, who yet fail to respond to treatment after a sufficient interval, should be most rigidly interrogated, and in many cases the suspicion of masturbation will be verified. It is almost useless to try any form of treatment, or to expect to obtain any definite results, in these functional neuroses if the habit is not discovered and corrected. The author says that his own opinion may differ from that of others, but from his experience he would rather treat any other form of nervous disease than a case of masturbational neurosis.

Electro-fanitis—A New Summer Complaint.—The approach of warm weather brings to mind some words in the *Indian Lancet* of November 1, 1900. That journal says:

“A new hot-weather ailment has whirled into existence. It is called ‘electro-fanitis’ and hails from the United States, the land of the electric fan. It is a sneezing, coughing cold in the head caused by the germ-laden breezes of the electric fan. It is almost epidemic. Unless properly cured, electro-fanitis may develop into two other diseases of the same family—tonsillitis and bronchitis. The most distressing and annoying characteristic of electro-fanitis is that it is never contracted except in hot weather, and there is nothing more distressing than a summer cold. Being caused by artificial atmospheric conditions, it is much more difficult to cure than an ordinary cold. A physician says of it: ‘The principal reason why the air currents produced by electric fans so readily cause inflammation of the mucous membrane of the head is that the draughts are sudden, and easily impress the system of the patient whose vitality has already been lowered by the heat. Furthermore, these currents of air are not the fresh waves of ozone which are in circulation outdoors. The artificial breezes are nothing but impure air forced into motion.’”

The Treatment of Exophthalmic Goitre with Collodion Dressings.—Dr. Allen T. Haight (*Chicago Medical Recorder*, March) reviews the literature on the symptomatology, pathology, and ætiology of exophthalmic goitre, and says that since it has been shown that the majority of writers on the subject of exophthalmic goitre coincide with him in believing, first, that the toxic conditions are due to a secretion or overflow of secretion of the thyroids; and, secondly, that the toxic effect produces the exophthalmos, rapid heart, and pulse action, he is sustained both in his theory and in his practical observations, that if the goitre is reduced, the thyroid secretion is reduced, and hence also the toxæmia. He, therefore, submits his method of reducing goitre by flexible collodion dressing. His attention was called to this treatment of goitre three years ago, after using collodion as a valuable aid in treating two cases of Hodgkin's disease in twin brothers.

When collodion is spread upon the skin, the evaporation of its ether causes its dissolved constituents to solidify and contract and become very adhesive, thereby compressing the goitre and reducing its size and secretive function, as the amount of blood supply is largely shut off. With the decrease in thyroid secretion we obtain a corresponding decrease in toxæmia and symptoms of the disease. As the thyroid gland lies in apposition with the upper part of the trachea and larynx and is covered by the omohyoid, sternohyoid, and sternothyroid muscles, it is, when enlarged by dilatation of its vessels,

like a water-soaked sponge, easily compressed and held so by collodion. He has employed this method of treatment in six cases of exophthalmic goitre, two males and four females, of ages varying from twenty-seven to fifty-four years, with enlargement of the thyroid in each case. He has not had an opportunity to use this treatment on that form of Graves's disease in which no enlargement of the thyroid is observed, so he cannot state whether collodion dressing would be of benefit or not in those cases.

The author then records the case of a married woman, forty-eight years of age, in whom the goitre was reduced and systemic symptoms disappeared under the topical application of collodion, accompanied by the administration four times a day of ten grains of potassium iodide and one drachm of syrup of hydriodic acid. The applications were made at intervals of three or four days. There has been no return of the disease. The author says that in each of his cases, of which he has had several, after the first application of the collodion all the symptoms were more or less decreased, the pulse rate, especially, being lowered from 10 to 15 beats a minute, and in one case 30 beats. In four cases all symptoms of the disease have disappeared. The average length of treatment was two or three months, and the period of observation from three to six months. Some dermatitis occurs. Pressure on the trachea may cause trouble at the first application, but soon subsides. The chief discomfort is interference with the movements of the head.

In making the application of collodion, the following points are to be observed: 1. The collodion must be absolutely fresh, so that the maximum degree of contraction will be obtained at each application. 2. Rapid evaporation will be secured by using from 20 to 30 pounds of air pressure, thereby increasing the compression fully one third. 3. The patient's head should be placed in an easy position, with muscles relaxed. 4. The collodion may be applied with a brush or cotton carrier and the pressure should be kept constant by repeated applications, as required, at intervals of from two to five days.

Interstitial Gingivitis, says Dr. Eugen S. Talbot in the *Chicago Medical Recorder* for March, produces four forms of bone absorption: Lacunar, or osteoclast; halisteresis; Volkmann's perforating canal; and osteomalacia, or senile absorption. Halisteresis and Volkmann's perforating canal absorption are naturally most common, since they are due directly to the inflammatory process, and are likewise more rapid in their action. Lacunar, or osteoclast, absorption is nearly always present, but is slow. Osteomalacia, or senile, absorption is a natural process and attacks every individual sooner or later. Interstitial gingivitis is recognized by puffiness and bleeding of the gums. Absorption of the alveolar process causes a recession of the gums from the necks of the teeth, thus leaving the necks exposed. On account of the transitory nature of the alveolar process, if the inflammatory process is not arrested the teeth will finally loosen and drop out. Pus infection frequently takes place. This occurs especially about the necks of the teeth, and the resulting products are taken into the stomach, producing indigestion. Treatment consists in the patient's drinking eight or more glasses of pure water each day, in brushing the gums with a stiff tooth brush three times a day, thereby causing them to bleed, and in the employment of proper mouthwashes. Tincture of iodine should be used upon the gums and alveolar process every other day until they are restored to health.

Original Communications.

ON TENONITIS AND TENONTOHECITIS
PROLIFERA CALCAREA.*

By CARL BECK, M. D.,
NEW YORK.

THE patient is a tailor, forty-two years of age, born in Russia, who immigrated twenty years ago. There is no family history. Thirteen years ago he noticed a small swelling of his great toe, which remained painless for several months. The toe became gradually reddened then, and on its plantar side an ulceration of the size of a penny formed. Soon after the patient got chills, pain also developing within the whole foot. Dr. Max Bracker, who was called in then, found a septic phlegmon which seemed to originate from the meta-

exarticulation he did very well for two years. About eleven years ago a small and painless swelling formed on the dorsal surface of his right hand, the size of which increased gradually. Sometimes the swelling seemed to be somewhat less. At last it became considerable, but until it became painful no medical advice was sought.

On September 22, 1900, when I first saw the patient after exarticulating his great toe, I noticed a globular tumor on the dorsum of his right hand, the size of which corresponded to that of a moderately large apple (Fig. 1). Its surface was dark red, its consistence irregular, some parts of it being hard, while others appeared soft to the touch. The centre of the tumor was occupied by a large ulceration, which was surrounded by several fistulous tracts from which turbid seropus issued.

My first impression was that the tumor represented an osteosarcoma, and I was afraid that I should be

FIG. 1.

tarsophalangeal joint of the great toe. Severe general symptoms soon supervened, and Dr. Bracker asked me to amputate on the same day. In exarticulating the great toe late in the night, I found a joint which had undergone considerable change. The bones were eroded and the joint contained a few calcareous concretions.

It then seemed to me that we had to deal with arthritis urica, which had produced ulceration of the skin above the urates, thus inviting septic infection. Little attention was given to the concretions, because the general infection, above all, was the subject of our consideration. These circumstances, together with the poor surroundings and the late hour, may serve as an excuse for my not having given more attention to the exarticulated toe.

From that time I did not see the patient again for nearly thirteen years. He then reported that after the

*Read at the annual meeting of the Medical Society of the State of New York, Albany, January 30, 1901.

compelled to insist upon speedy amputation. But I decided to consult the Röntgen rays, which proved to be a valuable means of information, since the true condition was at once precisely defined.

As will be seen from Fig. 2, which was taken under the influence of intense irradiation, the third metacarpophalangeal joint was the seat of a focus of inflammation. The first phalanx was grown together with the metacarpus in a laterally dislocated position. The cortex of the condylar side was totally destroyed, appearing as if scooped out with a gouge. By faint irradiation, the outlines of the tumor appeared well marked, as will be evident from Fig. 3. Fig. 4 shows the bones but faintly, but permits of distinct recognition of the various shades of the tumorous portions; it was taken under powerful irradiation and a short exposure. The light areas of Fig. 4 show the suppurating portions, while the dark shades correspond to the calcareous areas. These, as shown also by the subsequent opera-

FIG. 2.

FIG. 3.

FIG. 4.

tion, were the predominating elements of the tumor. It now became evident that there was a chronic inflammatory process, probably of a tuberculous nature.

The extirpation, which I performed on September 25, 1900, at St. Mark's Hospital, showed the defect of

FIG. 5.

the bone (compare Fig. 2) filled with yellow cheesy masses, the synovia being partially destroyed at the same time. But the most surprising feature of the condition was that the extensor tendons of the digits, excepting the thumb, appeared as if cemented into one mass of mortar. In dividing this mass the knife gave a loud, grating sound.

Of the tendon of the third finger, only a few rudimentary fascicles had remained, so that it had to be sacrificed entirely. The fascicles of the second and fourth extensor tendons were kept apart by the concretions. They were, in fact, so much incrustated that only a small portion could be left. The weight of the whole amount of the calcareous mass removed proved to be eighty grammes. Fig. 5 shows a calcareous residuum four weeks after the removal of the tumor; Fig. 6, a solitary concretion which made its appearance three months after the operation, when cicatrization had seemed to be almost perfect. Two weeks later, shortly

before the wound had closed entirely, a small concretion appeared again (Fig. 7).

The microscopical examination, for which I am indebted to Dr. Henry T. Brooks, showed round-cell granulations and the presence of staphylococci, but no evidence of tuberculous bacilli. There were also deposits of phosphates and carbonates of calcium. The fragments of the tendons showed granulation of the circumfascicular and interfascicular connective tissue. Hæmatoxylin colorized the degenerated tissue dark-brown violet, and picrocarmin changed it into red. Recovery was slow, and did not become perfect until nearly four months after the operation. There is still now, seventeen weeks after the operation, a slight stiffness of the fingers. The general condition is very good.

I am under the impression that the toe which I had exarticulated thirteen years before was the seat of the

FIG. 6.

same affection. The case will remain under observation, and a report will be published.

Now, what was the integral character of this disease? There was a much degenerated (cheesy) tissue in the state of necrobiosis, which seemed to have a sort

of magnetic effect, so to speak, on the dissolved calcareous salts, inducing them to amalgamate. Such petrifications are found in tuberculous (cheesy) foci of the lungs, and not infrequently in endocarditis and pericarditis, in old pleuritic bands, in uterine myomata, and in

FIG. 7.

renal epithelium. In the walls of blood-vessels, as well as in degenerated thyroid glands, I have had an opportunity, by means of the Röntgen rays, to define the mode of petrification. (See *The Value of the Röntgen Rays in Arteriosclerosis*, *New York Medical Journal*, January 22, 1898; *Allgemeines über den Kropf und seine Behandlung*, *New Yorker medicinische Monatsschrift*, October, 1900; and *Fortschritte auf dem Gebiet der Röntgenstrahlen*, iv, 3.)

The tendons and their sheaths seem to be but seldom the seat of predilection for calcareous deposits. Still, with the increasing popularity of the Röntgen rays more light may also be thrown upon the pathology and significance of this hitherto unknown disease, for which I have suggested the name *tenontitis* and *tenontotheitis* (instead of *tendinitis* and *tendovaginitis*) *prolifera calcarea*.

A COMBINED
INTRANASAL AND EXTRANASAL OPERATION
FOR THE CORRECTION
OF A
CONGENITAL CONCAVE VERTICAL AND
LATERAL DEFORMITY OF THE NOSE,
WITH THE REPORT OF A CASE.*

By BURTON S. BOOTH, M. D.,

TROY, N. Y.

ON September 9, 1897, I was consulted by Miss S., then eighteen years of age, who complained of a post-nasal trouble, which upon examination proved to be due to a slight thickening of the lymphatics in the vault of the nasopharynx. Examination of the nasal fossa revealed a deviated cartilaginous sæptum; the convexity, which was high up near the dorsum, was to be seen in the right nostril. Examination of the external nose revealed the following condition: The nasal bones were non-developed and appeared to spread, especially at their lower ends, leaving a V-shaped space through which could be seen the dorsal edge of the sæptum. The latter assumed a slight curve, the convexity being to the left, thus leaving a depression on the right side of the nose over the nasal bone. This condition, together with an atrophy of the muscles and tissue, gave a curved and sharp appearance to the bridge of the nose, so that with the saddle-back deformity due to the spreading and non-development of the nasal bones, and to some extent a like condition of the ethmoidal and sphenoidal bones, the case was one in which I was not enthusiastic to recommend an operation, but, instead, advised the use of a nasal wash and dismissed her with a request that

FIG. 1.

she return again in a few weeks. From that time until February 16, 1900, I lost sight of her. On this date she consulted me again and was desirous of having an opera-

*Read before the Section in Laryngology and Rhinology of the New York Academy of Medicine, February 27, 1901.

tion to relieve the embarrassing deformity, which was a source of constant annoyance. After a thorough examination I decided that two operations would be necessary—one to correct the deviation of the septum, and

FIG. 2.

the other the saddle-back and pinched-like deformity of the external nose. Fig. 1 will give some idea of the appearance of the nose before the operation, although the portrait was taken long before she decided to be operated on, and the position assumed was one calculated to hide rather than to show the deformity.

On March 8, 1900, I did the intranasal operation to correct the deviation of the septum, as follows: After irrigating the nose, I applied a ten-per-cent. solution of cocaine by means of cotton and an applicator, rubbing it into the membrane thoroughly for about ten minutes, after which I applied a solution of adrenal capsule in the same manner for about one minute; by this time the field of operation was completely anaesthetized and the membrane appeared thoroughly blanched. A sharp-pointed bistoury was now plunged through the most prominent portion of the convex septum into the opposite nostril, the cutting surface of the knife directed anteriorly; after I had made a sufficiently large opening a blunt-pointed, curved bistoury was substituted to avoid injuring the tissue of the opposite nostril, and made to cut through the warped cartilaginous septum anteriorly. The bistoury was then reversed and passed through the warped cartilaginous septum posteriorly until the bony septum was reached. A small nasal saw, such as is used to remove spurs from the septum, was now substituted, and with it I divided a small portion of the bony septum which was included in the deviation. The operation had thus far caused but very little pain and comparatively no hæmorrhage. I now applied more cocaine and adrenal as in the beginning. In order to completely destroy the resiliency of the septum, and at the same time relieve the curved appearance in the bridge of the nose, I deemed it necessary to make two incisions, the first running from the bridge to the floor of the nose, crossing the anteroposterior incision, dividing the cartilaginous septum at the most prominent part of its con-

vexity, the same as in the Asch operation; the second incision was made to divide that portion of the septum lying between the upper part of the anteroposterior incision and the bridge of the nose, just anterior to the bony septum. These incisions were made with the sharp-pointed bistoury. The septum was now grasped between the broad blades of an Adams forceps, and by a rotary movement the resiliency of the septum was broken up. The index finger was then introduced into the nostril containing the convexity, and the septum was pushed into the opposite nostril. The latter part of the operation was somewhat painful, but not enough so to interfere with or restrict in any way the procedure. In order to keep the upper part of the septum in the median line, it was necessary to plug the attic of the right nasal vestibule with tannic-acid gauze. The nasal splints ordinarily used were not deep enough to hold it in proper place, but by this means, together with the aid of a nasal splint, I was able to keep the septum in a good position until it healed. (The splint was pushed under the gauze and helped to hold it in place.)

The patient was kept in bed for forty-eight hours after the operation, at the end of which time the splint and packing were removed, the nostrils were irrigated with normal warm aseptic salt solution, after which the gauze and splint were replaced. This line of treatment was continued on alternate days for four weeks, when the parts were found to be completely healed and in good position, the curve having entirely disappeared from the bridge of the nose and its contour being very much improved in appearance, although the saddle-back deformity and pinched expression were still present.

On April 14th, under general anaesthesia, ether being employed, the following extranasal operation was per-

FIG. 3.

formed to correct the external deformity: The patient being well under the anaesthetic, and the parts having been previously prepared, an incision was made in the median line over the dorsum of the nose extending from

a point about in the centre of the glabella of the frontal bone to near the distal end of the cartilaginous sæptum. The soft parts having been cut through and pushed aside, the nasal bones were loosened from their bony attachment by means of a strong forceps, after which they were elevated, especially the right one, which was more depressed than the left. Pieces of gauze were now packed in each nostril, under the nasal bones, to hold them in place. The next step in the operation consisted in drawing into place, to fill in or relieve, as it were, the pinched-like appearance of the nose. This was accomplished by means of a curved needle armed with a piece of aseptic catgut which was made to take a circuitous course in the following manner: The needle was inserted into the deep tissue at a point corresponding with the lower border of the compressor muscle on the left side of the nose; it was directed upward and made its exit about three quarters of an inch above its entrance. It was then passed over the dorsum and made to enter the deep tissue of the right side at a point corresponding with the point of exit on the left side, passing downward in a shirring-like manner, emanating at a point opposite the point of entrance of the left side. The ends were now tied carefully, pulling the soft tissue up so as to fill in the depressions. This being done, the skin was brought into place and held there by a subcutaneous suture, silk-worm-gut being used; the nose was dusted over with aristol and dressed, the patient was placed in bed and kept there twenty-four hours, at the end of which time she was allowed to get up, and the wound was dressed.

Everything looked favorable and the dressing was replaced. The wound was looked after every day for five days, when it was found that it had healed by primary union. The silkworm-gut suture was now withdrawn and a light dressing kept on for a few days, when the patient was dismissed, the result being most satisfactory, as will be noticed in Figs. 2 and 3. I may add that little or no scar resulted from the incision, thanks to the subcutaneous suture, and at the present time there exists nothing but a slight scratch, hardly discernible.

I am indebted to Dr. John O. Roe, of Rochester, for the information I obtained from his article which appeared in the *American Medical Quarterly* for June, 1899. Although I was unable to follow his method of operation, I obtained a great deal of information which was of assistance to me in the above-described operation.

I believe that the combined use of cocaine and adrenal capsule as a local anæsthetic and hæmostatic in correcting deviation of the sæptum is preferable to that of a general anæsthetic, at least in a large proportion of cases, for the following reasons:

1. There is less immediate danger from heart failure or suspension of breathing, accidents not uncommon in chloroform and ether anæsthesia, even in the hands of the most intelligent and practised administrators.

2. The hæmorrhage during the operation is *nil*. But, many will say, what occurs after the operation? I believe the danger of secondary hæmorrhage following the use of adrenal is offset by the danger of the suspension of animation following the use of a general anæsthetic. Especially is this true if every precaution is observed to guard against this accident; for instance,

packing the nostrils with tannic-acid gauze is a precaution not unworthy of observance. The astringency of the tannin cannot be denied, and it certainly does insure, to a certain extent, against secondary hæmorrhage. After forty-eight hours the gauze can be removed and the splint substituted.

Citing a case in point, I may say that, on December 1, 1900, in my office, I operated upon Miss Lottie L., of Johnstown, N. Y., to correct a deviated sæptum. Cocaine and adrenal were used for their anæsthetic and hæmostatic properties. A ten-per-cent. aqueous antipyrine solution was used to paint the sæptum of the right nostril as an experimental precaution against secondary hæmorrhage. Instead of inserting a nasal splint in each nostril, as is usually done at the completion of this operation, I packed both nostrils with tannic-acid gauze and sent the patient home with directions to use ice-cloths over the nose and to keep quiet. In three hours a slight hæmorrhage occurred in the right nostril, the one in which I had used the antipyrine. The bleeding was no more severe than I have frequently seen when the operation had been done under general anæsthesia, and it ceased upon removing the packing from that nostril and injecting it with a solution of tannin. The packing in the left side was not disturbed for forty-eight hours, when it was removed, and both nostrils were washed with a salt solution. Upon examination, the sæptum was found to be in the median line. A clean nasal splint was fitted to the left nostril and the patient was sent home, with a request to return in forty-eight hours.

It will be seen from the history of this case that the packing had kept the sæptum in as good position as a splint would have done. I admit that the patient was obliged to breathe through the mouth while the packing was in place, but I also maintain that this is the case in the majority of instances in which the splint is used, because it is usually occluded by clotted blood. The danger of ear complications following the use of the packing is no greater than that following the use of the nasal splints.

3. The operator can see what he is doing at every step during the operation. This is an advantage not secured under general anæsthesia.

4. The patient can sit upright and hold his head in place during the operation—an obvious advantage.

5. No special instruments are necessary—a step toward simplifying the operation.

6. The operation can be done as well in an office as in a hospital. This not only saves time and expense, but will be preferable to a large percentage of patients.

7. The pain is insignificant, and certainly less distressing than the nausea and vomiting following the use of ether.

In conclusion, I wish to say that I am aware that there are cases in which it is necessary to use a general anæsthetic, and that I do not wish to be understood as

advocating the use of local anæsthesia to the exclusion of general anæsthesia. For example, in small children and in neurotic subjects, I believe general anæsthesia is imperative.

HOSPITAL APPOINTMENTS. ARE THEY OPEN TO WOMEN?

BY MISS HELEN MACMURCHY, M. B.,
TORONTO, CANADA.

"THEY are unusually valuable, and the men get them," says Dr. Garrett Anderson, the greatly esteemed dean of the London School of Medicine for Women, in a recent article.¹

The dean is alluding particularly to interne or resident medical assistant appointments.

But women have been practising medicine only half a century. Dr. Elizabeth Blackwell graduated in 1849, and the first woman to practise medicine in England matriculated at the University of St. Andrew's, in 1862, "without any warning to the authorities or preliminary elevation of a feminine banner, in all quietness and discreetness, asking admission to the medical classes. This first student, one of those quiet women who attain their objects without that blowing of trumpets which is supposed to accompany feminine efforts . . . was Mrs. Garrett Anderson. Work so serious and genuine as hers probably acted with good effect."²

Considering the short time, the great competition for these posts, and the years required for great movements to develop, is the number of appointments held by women physicians as small as it seems?

To aid in answering this question, the following list has been compiled for the Woman's Medical College, Toronto, Canada. The list shows a total of 559 medical appointments—government, municipal and hospital—held by women physicians (and also 11 appointments recently opened to competition). Of these, 215 are resident; 302 (including 114 resident) are in the United States, and 188 (including 99 resident) are in the British Empire.

ENGLAND.

- London.*—1. *The Royal Free Hospital.—Staff consists of 44 physicians and surgeons, of whom 12 are women, holding the following appointments: 1 medical registrar, 1 surgical registrar, 1 assistant pathologist, 1 demonstrator of pathology, 3 anæsthetists, 3 medical assistants, 2 surgical assistants, 1 ophthalmological assistant, 1 throat, nose, and ear assistant, 2 resident assistant medical officers.
2. The New Hospital for Women.—Staff consists of 41 physicians and surgeons, of whom 28 are women, holding the following appointments: 4 consulting staff, 5 physicians and surgeons for in-patients, 6 physicians and surgeons for out-patients, 6 clinical

- assistants, 2 ophthalmic surgeons, 3 anæsthetists, 1 pathologist, 3 resident assistant medical officers.
3. Battersea District Maternity Hospital.—2 resident medical officers.
4. Canning Town Hospital.—1 consulting surgeon, 1 consulting physician, 1 resident medical officer, 1 assistant medical officer.
5. Clapham Maternity Hospital.—2 physicians for in-patients and out-patients, 2 resident house surgeons.
6. Belgrave Hospital for Children.—Resident medical officer.
7. *Bethnal Green Workhouse and Infirmary.—2 assistant medical officers.
8. *Camberwell Infirmary.—2 assistant medical officers.
9. Centre London Throat and Ear Hospital.—Clinical assistant.
10. Chelsea Hospital for Women.—2 anæsthetists.
11. East London Hospital for Children.—Clinical assistant.
12. Evelina Hospital for Children.—3 clinical assistants.
13. Golden Square Throat Hospital.—Clinical assistants.
14. *Greenwich Infirmary.—Assistant resident medical officer.
15. North London Hospital for Consumptives.—Clinical assistant.
16. North Western Hospital, Hampstead.—Assistant resident medical officer.
17. Paddington, Victoria Orphanage.—Assistant resident medical officer.
18. Plaistow Maternity Charity.—Medical officer.
19. Royal Ophthalmic Hospital (Moorfields).—2 clinical assistants.
20. St. John's Skin Hospital.—Clinical assistant.
21. *St. Pancras Workhouse.—Resident assistant medical officer.
22. Walthamston (N. E.) General and Children's Hospital.—House surgeon.
23. West End Hospital for Nervous Diseases.—Registrar.
24. Western Ophthalmic Hospital.—Clinical assistant.
25. West Ham Workhouse and Schools.—Resident assistant medical officer.

Provincial.

1. *Birkenhead.*—Maternity Hospital.—Honorary surgeon.
2. *Birmingham.*—Midland Hospital for Women and Children.—Honorary physician, anæsthetist.
3. **City Asylum.*—Resident medical officer.
4. *Free Hospital for Children.*—Acting physician.
5. *Brentwood.*—*Essex Co. Asylum.—Third assistant medical officer.
6. *Bristol.*—Royal Hospital for Women and Children—House surgeon.
7. *Colchester.*—E. Anglian Sanitarium for Consumption.—Resident medical officer.
8. *Gateshead on Tyne.*—*Workhouse.—Resident medical officer.

¹ *The Gentlewoman*, January 5, 1901.

² *Memoir of Principal Tulloch*, by Mrs. Oliphant.

*Resident staff composed of men and women physicians.

9. *Huddersfield*.—*Infirmiry.—Assistant house surgeon.
10. *Hull*.—*City Asylum.—Assistant medical superintendent.
11. *Victoria Hospital for Women and Children*.—Assistant physician.
12. *Victoria Hospital for Sick Children*.—Honorary assistant physician, house surgeon.
13. *Lancaster*.—*County Asylum.—Resident assistant medical officer.
14. *Lincoln*.—*Bracebridge Asylum.—Resident medical officer.
15. *Liverpool*.—*Victoria Infirmiry*.—Resident medical officer.
16. *Samaritan Hospital*.—Honorary physician.
17. *Manchester*.—*Clinical Hospital for Women and Children*.—Assistant physician, house surgeon.
18. **Chorlton Union Hospital*.—Second resident medical officer.
19. *Merton (Surrey)*.—**Merton Asylum*.—Resident assistant physician.
20. *Minston (York)*.—*W. Riding Asylum*.—Resident assistant physician.
21. *Morpeth (Northumberland)*.—**Morpeth Asylum*.—Resident medical officer.
22. *Newcastle*.—**Union Infirmiry*.—Resident medical officer.
23. *Nottingham*.—*Hospital for Women*.—Assistant surgeon.
24. *Oxford*.—*Eye Hospital*.—Senior clinical assistant, house surgeon.
25. *Rotherhithe*.—*Cottage Hospital*.—Medical officer.
26. *Salford*.—**Union Infirmiry*.—Resident medical officer.
27. *Sheffield*.—**Wadsley Asylum*.—Resident medical officer.
28. *Children's Hospital*.—Resident medical officer.
29. *Tooting*.—**Fever Hospital*.—Assistant resident medical officer.
30. *Tooting (Lower)*.—*Grove Hospital*.—Assistant resident medical officer.
31. *Tunbridge Wells*.—*Eye, Ear and Throat Hospital*.—Assistant resident medical officer.
32. *Virginia Water (Surrey)*.—**Holloway Sanatorium for the Insane*.—Resident medical officer and pathologist.
33. *Woodford Bridge (Essex)*.—**London Co. Asylum*.—Assistant medical officer.
34. *York*.—*The York Dispensary*.—Resident medical officer.
35. *York*.—**The Retreat (Quaker Asylum)*.—Resident medical officer.

SCOTLAND.

1. *Bridge of Weir*.—*Consumption Hospital*.—Medical officer.
2. *Edinburgh*.—*Hospital for Women and Children*.—

- Physician, resident medical officer, assistant resident medical officer.
3. *Deaconess Hospital*.—Resident medical officer.
4. **Royal Hospital for Children*.—Resident medical officer.
5. **Victoria Hospital for Consumption*.—Resident physician.
6. *Dumfries*.—**Crichton Asylum*.—Resident medical officer.
7. *Dundee*.—**Workhouse and Infirmiry*.—Resident medical officer.
8. **Royal Infirmiry*.—Assistant resident medical officer.
9. *Gartnavel*.—*Asylum*.—Staff appointment.
10. *Glasgow*.—*Samaritan Hospital*.—Assistant anæsthetist, 2 resident house surgeons.
11. *Victoria Infirmiry*.—Gynæcologist.
12. *Maternity Hospital (W. Branch)*.—Physician in charge, outdoor house surgeon.
13. *Royal Hospital for Children*.—Extra physician.
14. *Lock Hospital*.—Assistant surgeon.
15. *Royal Infirmiry*.—House surgeon (gynæcologist).
16. *Govan (S.)*.—*Fever Hospital*.—Resident physician.
17. *Kirkmichael (Perthshire)*.—*Parish*.—Parish medical officer.
18. *Larbert (Stirlingshire)*.—*Asylum*.—Resident medical officer.
19. *Leith*.—**General Hospital*.—House physician, assistant house physician, outdoor resident surgeon.

Orkney Islands.

20. *Eday*.—Medical officer.
21. *Westray*.—Medical officer.
22. *Loughoyne on Hoy*.—Medical officer.

IRELAND.

1. *Belfast*.—*Mater Infirmorum*.—Resident physician.
2. *Cork*.—*Lindville Asylum*.—Resident medical officer.
3. *Dublin*.—*Coombe Maternity Hospital*.—Resident and assistant to the master.
4. *Richmond*.—Assistant medical officer, gynæcologist.

AUSTRALIA.

1. *Adelaide*.—*Adelaide Hospital*.—Resident medical officer.
2. *Brisbane*.—*Women's Hospital*.—Attending surgeon.
3. *Children's Hospital*.—Out-patient physician.
4. *Melbourne*.—**Melbourne Hospital*.—2 resident medical officers.
5. *Queen Victoria Hospital for Women*.—Resident medical assistant.
6. *Children's Hospital*.—Resident medical assistant.
7. *Sydney (N. S. W.)*.—*Children's Hospital*.—Resident medical officer.

SOUTH AFRICA.

The County Medical Service.—Medical staff.

The Municipal Ambulance Service.—Medical staff

St. Petersburg.—City Hospitals.—55 staff appointments.

Thirty-six City Districts.—15 medical officers.

HOLLAND.

Amsterdam.—Municipal Physicians.—Physician to the female officials.

SWITZERLAND.

1. Berne.—Psychiatric Clinic.—Assistant physician.

2. Zurich.—Obstetrical and Gynæcological Clinic.—Fourth assistant physician.

3. Psychiatric Clinic.—Second assistant physician.

COREA.

Seoul.—The Corean Government.—Physician to the imperial household.

NOTE.—Corrections and additions to this list will be very welcome.

TWO ELMS, SHERBOURNE STREET.

An Institute of Tropical Medicine has been established by the city of Hamburg, with the support of the German Empire. The director of the institute is Dr. Nocht, formerly a surgeon in the German army, a student under Professor Koch, and medical officer of the port of Hamburg during the cholera epidemic of 1892. Dr. Ollwig, who accompanied Professor Koch on his tropical expedition, will be assistant director of the institute.

A CONTRIBUTION TO
THE EXPLANATION OF THE NATURE OF
THE SO-CALLED PREDISPOSITION
TO INFECTION WITH STAPHYLOCOCCI.*

BY F. W. GAERTNER, M. D.,

SAGINAW, MICHIGAN.

PREDISPOSITION is an expression in medical science which is used daily, but the nature of it has not yet been ascertained. Aristotle knew the sense of the word and distinguished between a predisposition which was inherited and one which was acquired. This is a classification which still exists and which always will exist. If we ask ourselves what predisposition is—the different susceptibilities of individuals for diseases—it is not very difficult to arrive at the conclusion, by experience and consideration, that predisposition to a disease is either inherited or acquired by certain changes of the whole organism, or of only single organs, favorable to the reception and cultivation of germs.

According to our knowledge of to-day, nearly every disease in which predisposition is in question results from an infection with pathogenic micro-organisms. In what way these germs immigrate into the body, whether through the respiratory or the digestive tract, or through the pores of the skin, or by direct infection of the skin, does not matter. It is sufficient to know that man is constantly exposed to this noxiousness. But how it happens that one is more or less susceptible to these noxious germs than another, we must confess that we do not know as yet sufficiently. In spite of that, this enemy of the human body, working in the dark, is well known and feared by every layman on account of its effects; in spite of that, every physician acknowledges the fact of a predisposition; we only have suppositions as to what conditions are favorable for it.

In studying the effect of subcutaneous injections of *Staphylococcus pyogenes aureus* in rabbits, I have always obtained the same results, provided I took the same quantity of a pure culture each time. Five rabbits were infected under aseptic precautions in the subcutaneous connective tissue of the back, two inches from the scapula and three fourths of an inch from the vertebræ, with the same quantity of the same culture. The wound, about half an inch long, was closed tight by one stitch. After twenty-four hours quite an inflammation was perceptible, which, by paling off, gave place to a bulging of the skin where the infection took place. This bulging, which had the consistence of soft rubber, broke on the third day *post infectionem*, after the redness had disappeared entirely. The pus which came out of the wound dried up quickly and closed it by a thick scab. But under this natural cover the original abscess spread to a phlegmon about two inches square which, after the removal of the scab by pressure, emitted a thick, whitish pus. This pro-

*Read before the third Pan-American Medical Congress, held in Havana, Cuba, on February 4, 5, 6, and 7, 1901.

cess reached its greatest extent on the twelfth day, from which time on the phlegmon did not spread any further. The pus formation was very profuse up to the above-mentioned time, but confined itself to that circumference without involving further tissues. These animals were killed on the thirtieth day *post infectionem*, and the post-mortem gave in all five cases the same result, viz., after an extensive cutaneous section of the above-described bulge, a cavity appeared filled with thick pus separated in all directions from the normal tissue by large masses of connective tissue. This natural wall of protection, a product of the inflammation, had grown together so firmly with the muscles of the skin and the fascia resting underneath that a separation of these tissues was practically impossible. All the organs were found normal. It still has to be added that, except for a slight rise in temperature in the first days *post infectionem*, no general symptoms of blood-poisoning were noticed; on the contrary, the animals showed a marked alacrity and a fine appetite. The same experiments were tried on three more rabbits with the same result. Thus I secured a series of experiments which, with equal quantities of *Staphylococcus pyogenes aureus* injected, confirmed the fact of an equal effect of the same, and I could then start to investigate the conditions which favored the development of germs in the fluids and tissues of the organism.

Acting upon the fact which is observed by every general practitioner, that anæmic and chlorotic individuals are much more easily subjected to infectious diseases than individuals with the normal quantity and quality of blood, I endeavored to prove this well-known observation by experiments. I distinguished in them between a general and a local anæmia. The artificial anæmia was obtained by bleeding from the vena jugularis externa. From every animal in the ten respective cases, one tenth of all its blood, that is, according to its weight, two or three drachms, was withdrawn. After four days these animals were infected in the above-described way with staphylococci; at the same time, four animals with the normal quantity of blood were infected with the same quantity of the same culture. The hæmoglobin of the blood of the sound animals was in proportion to that of the anæmic ones, as fifty to thirty. The anæmic animals showed in the following days a very much quicker abscess formation than the normal ones. The phlegmon spread out to the size of the hand, while the sound rabbits only had a pus cavity of the size of a walnut. The general symptoms of the animals made artificially anæmic were very different ones. High temperature up to 106° F., bristling hair, no appetite, and increased thirst were the features, so that four of them died. The six others recovered very slowly after the phlegmon ceased to grow. A post-mortem of the rabbits did not show any pyæmic metastasis in any of the organs. But implantation of the blood from the hearts of those dead animals on agar-agar gave rise to exuberant cultures of *Staphylococcus pyogenes aureus*. In contrast to this development of

staphylococci was that with local anæmia. In two rabbits the main artery of the right ear was ligated, and in two others the right arteria cruralis just below Poupart's ligament. All four rabbits were infected with the same quantity of the same culture, each one of the two with the ligated right-ear arteries in both ears, and each one of the two with the ligated right crural arteries in both legs. The result was, that in the normally nourished ears and legs abscesses developed quicker than in the locally anæmic ones.

The difference in the results under these two apparently equal conditions has to be looked for in the entirely different effect of general and local anæmia. General anæmia represents in our case a general diminution of the blood, a poorer nourishing of the tissues, but a restitution of the quantity of the fluid of the blood without a simultaneous augmentation of the blood corpuscles. Thus, there existed on the fourth day after the bleeding considerable hydræmia before the regeneration of the blood corpuscles had begun, which could be learned by evidence from the hæmometer. In local anæmia we only have considerable decreased nourishing of the tissue without change in the quality of the blood. But its gradual regeneration by collateral circulation soon restores the poorly nourished tissues, and the growth of the cocci, which ceased almost entirely at the cessation of the blood supply after the ligation, continues in its normal above-described way. In general anæmia, therefore, only the qualitative alteration of the blood exerts a favorable effect on the increased growth of the cocci.

In order to prove still further that it was principally hydræmia, as a secondary state of the blood in anæmia, which produced a quicker rise of staphylococci cultures, the following experiments were made. The leading idea connected with them was the question Does the staphylococcus thrive better on or in hydræmic than in normal blood?

From two normal, sound rabbits—hæmoglobin fifty and fifty-five—I withdrew by the vena jugularis externa of each one tenth of their blood which I caught in three test-tubes and had it coagulate in an oblique position. At the same time I bled to death a rabbit which four days before I had made artificially anæmic—hæmoglobin thirty-five—the blood of which I also had coagulated in six sterilized test-tubes. All twelve I sterilized by keeping them four days in succession, two hours daily, in a thermostat at 154° F. Now, after the growth of any other germ was excluded, I applied with the same quantity of a pure culture of *Staphylococcus pyogenes aureus* a streak culture in each tube. After twenty-four hours there was in the anæmic and normal blood a very perceptible difference in the growth. The streak cultures in the hydræmic blood were spread in all directions in the characteristic way of the aureus, while the culture on the normal blood did not show any change. To be sure of this very important result, the experiment was once more repeated with the blood of the two anæmic rabbits men-

tioned above and that normal one, all three of which I bled to death. The same difference in growth of bacteria on the anæmic and the normal blood was obtained. But with these results it has not yet been proved why the hydræmic blood gives the better condition for the culture of the bacteria than does the normal one.

If we consider what a pathological state of blood hydræmia is in anæmia of the most variable origin, we have to locate it in disproportion to the red and white blood corpuscles on one side, and the water contents of the serum on the other. The latter has the task of compensating for the quantity of blood withdrawn by some artificial or pathological conditions, in taking up considerable water from the tissues. Thus the increased quantity of water in the blood serum, in comparison with the quantity of the solid ingredients of blood, causes hydræmia. It is, therefore, only left to examine whether the hydræmic serum indeed contains that agent which makes the staphylococci grow more actively in anæmia. That the other solid ingredients of the blood have no part in it, I proved with the experiment that staphylococci on a placenta sanguinis from hydræmic or normal blood hardly showed any growth, not to speak of its being a different one. In order to get a sufficient quantity of hydræmic and normal blood, I bled to death two rabbits which had been made anæmic four days before—hæmoglobin thirty—and two normal rabbits—hæmoglobin fifty. From these different quantities of blood I separated the serum with the usual technics and had it coagulated and sterilized in a number of test-tubes. On sterilization, this fact was so very conspicuous that it took fully twenty-four hours longer to coagulate the hydræmic blood serum than the normal one at a constant temperature of 158° F. A streak culture was now applied to both the hydræmic and the normal serum with a pure culture of *Staphylococcus pyogenes aureus*. A surprising difference in growth was the result. The whole oblique surface of the hydræmic serum was covered with that beautiful golden-yellow culture of *Staphylococcus pyogenes aureus*, while the staphylococci on the normal serum only showed a very small growth.

Not yet content with these results in considering whether this difference of growth also occurred in the circulating blood, I was reminded of the experiment of Wyssokowitsch, who proved that cocci injected into the blood would entirely disappear after twenty-four hours. Hence the fact that staphylococci thrive better on hydræmic serum than on the normal one, must coincide with the result of an injection of cocci into hydræmic circulating blood. These, therefore, ought not to disappear after twenty-four hours, but, multiplying, should cause symptoms which demonstrate a general infection.

For this purpose three rabbits were made anæmic by one tenth of their amount of blood each. On the fourth day after the bleeding I injected into the vena saphena magna of each one the same quantity of *Staphylococcus pyogenes aureus* culture, which was dissolved in an

0.7-per-cent. solution of sodium chloride. In order to confirm this the same quantity was injected into a normal rabbit. Eighteen hours afterward I could not find any cocci in the blood of the normal rabbit, while a streak culture on agar-agar with the blood of the anæmic animals proved a decided vitality of the cocci. Twenty-eight hours after the injection, one of the three anæmic rabbits died, and a streak culture made from its heart blood produced twenty-four hours later a large growth of staphylococci, but in the organs there have been no cocci found as yet. The second anæmic rabbit died fifty hours after the injection, and it showed in the last hours of its life the distinct symptoms of general infection, such as bristling hair, no appetite, unusual thirst, etc. Cultures of heart blood on agar-agar gave a positive result, and Gram's method showed great numbers of cocci in several glomerules and in the endothelium of the renal arteries. The third rabbit remained alive, but a very rapid and forced respiration gave the impression of an infectious pneumonia. On the sixth day after the injection I still could prove that staphylococci were in the blood, but on the eighth day they had disappeared. From now on the rabbit recovered very rapidly.* Three rabbits were kept for four days without any solid food, but they were allowed to drink all the water they wished. They lost heavily in flesh, the hæmoglobin decreased from fifty--fifty-two to thirty-eight--forty-one, but the quantity of the blood was not decreased, because of the compensating supply of water. Thus hydræmia existed. After these animals had been infected with the usual quantity of staphylococcus, a quicker and more proliferous formation of abscesses was noted than in the normal animals infected at the same time.

A further experiment, which also demonstrated the foregoing, which originated in the experiment of Kussmaul, who found that the quantity of water in the blood of animals fed with dry or seed nourishment varied perceptibly from that of animals nourished with grass food, was modified so that two rabbits were kept without food or water and were infected on the fourth day of fasting with the same quantity of staphylococcus. One of the animals from that time on only received sago and rice, the other one only grass and salad; no water was given to either of the rabbits. The success was astonishing: in the animal fed with green food an abscess developed in a very much shorter time than in the one fed with seeds. The abscess of the first-mentioned rabbit broke spontaneously on the third day, at which time the other rabbit showed only a small bulging at the place of the infection. To confirm this experiment, two rabbits were starved in the same way, infected with the same quantity of staphylococcus, and fed, one with green food, the other with seeds. To the latter, water was given in sufficient quan-

*There can hardly be any doubt that, according to all these experiments, it is the hydræmia which furnishes a favorable predisposition for the infection, and it will therefore not be difficult to understand the further investigations, because they rest on the same basis.

tities; in consequence, abscesses of the same size developed in both animals.

Another proof that the hydræmia is the main cause of the quicker cultivation and multiplication of germs in the body is obtained in the following experiment: Three rabbits were made anæmic by bleeding from the vena jugularis, three other rabbits were also deprived of one tenth of their blood, and all were infected at the same time in the same place with the same culture of staphylococcus. The same infection took place with two normal rabbits. After twenty-four hours the three rabbits which had been made anæmic four days before the infection with cocci had the first signs of an abscess.* On the fifth day *post infectionem* the first rabbits showed very profuse formations of pus; the normal animals had an open abscess of the size of a hazelnut, and those infected immediately after the bleeding, phlegmons of the size of a walnut. The pus formation of the latter animals, after their blood had become hydræmic—hæmoglobin thirty-five on the fifth day—surpassed the size of the abscesses of the normal rabbits, while the rabbits which had been made anæmic four days before the infection were ahead of all and showed the most favorable ground for the cultivation of germs.

The best analogue and illustration in practice of these last experiments is puerperal fever, which does not set in in most cases until from four to nine days after the infection. There is more or less loss of blood at every confinement, and because the restoration of the quantity of blood occurs faster than the restoration of the quality, the blood naturally becomes hydræmic, and it is just then that the first symptoms of a pyæmic infection alarm the attendants.

If, finally, we recall once more the results of all our experiments and take especially into consideration the demonstration of the first and the last facts of our investigation, showing that, by anæmia consequent on bleeding and starving, the infected animals showed a quicker multiplication than the normal animals infected in the same way, we need not hesitate to conclude that the conditions which favor a disposition to infectious diseases have to be looked for in the hydræmia of anæmia.

PNEUMONIA,
ITS PROPER MANAGEMENT IN CHILDREN;
HYGIENIC, DRUG, AND DIETETIC DETAILS.†

By LOUIS FISCHER, M. D.,

NEW YORK,

ATTENDING PHYSICIAN TO THE CHILDREN'S SERVICE OF THE
GERMAN POLIKLINIK, ETC.; AUTHOR OF "INFANT
FEEDING IN HEALTH AND DISEASE."

The statement is sometimes made that pneumonia can be aborted. Thus it frequently happens that a child

*With considerably less symptoms the two normal animals followed, while in the freshly anæmic ones hardly any change at the place of the infection was to be seen.

† Read in a discussion on pneumonia at a meeting of the Eastern Medical Society, held April 12, 1901.

will suddenly be attacked with high fever with a correspondingly accelerated heart's action, and an increased frequency of respirations, disturbing the normal ratio of the respiration to the pulse—which usually is 1-4—so that it becomes 1-2 or 1-3. When the latter condition exists, the onset of pneumonia may be suspected. A vigorous treatment, consisting of the application of a mustard foot bath for two or three minutes to produce copious perspiration, besides the use of one-drop doses of tincture of aconite, repeated every hour for six successive doses, and the administration of half-drachm doses of spiritus Mindereri, will aid in establishing diaphoresis, thus reducing the temperature and frequently causing a total disappearance of the symptoms. At such times the administration of small doses of calomel, from one tenth of a grain to half a grain, repeated every three hours until liquid stools are produced, will frequently eliminate by means of the bowels decomposing food, which may have been the cause of this toxæmia, resulting in the febrile symptoms previously noted.

TREATMENT WHEN THE DISEASE IS ESTABLISHED.

Fever Treatment.—When high fever persists in a weak child with very low resisting power, such fever must be reduced. To be plainer, the child's system must be carefully watched while fever is in progress. One child will tolerate a temperature of 105° F., laugh and play, and take its food regularly, while another child in a similar pulmonary condition will show extensive cerebral irritation, somnolence, tremor, twitching of the muscles, possibly convulsions, at a temperature of perhaps only 103° or 104° F. In this latter instance, it merely shows that the poison from the pneumococcus infection has overwhelmed the nerve centres governing heat production, and in such instances, when decided nervous or cerebral symptoms present themselves, "a reduction of temperature is demanded," or we must not be surprised to see convulsions set in with probably a fatal termination.

How Shall we Reduce the Temperature in Children?—When we consider that antipyretic drugs depress the nerve centres governing heat production and increase the work of the emunctories, already loaded down by poison brought to them for elimination, it can be seen that their use is contraindicated. Those who believe in phagocytosis may be reminded that antipyretics arrest the development of leucocytosis, and thus remove one of the means of destroying the germs of the disease according to one theory, or the antitoxine generated or developed according to another. (Hobart A. Hare.)

Jacobowitsch and Muller and many others have proved conclusively that antipyrine decreases the elimination of urea by the urine. It also decreases the urinary flow, which is a very harmful effect, when we consider that it is of great importance to eliminate effete matter from the body. That antipyretics depress the heart's action is only too well known, and therefore,

rather than combine them with musk or camphor or other cardiac stimulants, I have discarded them for a great many years.

In a paper read before the Post-graduate Clinical Society, on The Treatment of Hyperpyrexia in the Course of Pneumonia in Children, based on a series of cases treated by me in the babies' wards of the Post-graduate Hospital, about ten years ago, great stress was laid on the depressing effect of antipyretics in the treatment of this disease. My only success has been achieved by the use of cold in the form of the sponge bath, using alcohol and water, or frequently acetic ether, the latter to be used with great care, owing to its volatile and inflammable tendencies.

When fever persists in spite of sponging the skin with tepid water to which alcohol is added, or sponging with acetic ether, a good plan is to apply a cold compress consisting of a towel or sheet wrung out in cold water and placed next to the skin. This is to be repeated as often as every half-hour, unless special indications demand that it be used oftener.

Henoch insists on the use of cold applications in the following words: 1. The sudden application of cold externally causes a deep inspiration and consequent forcing of air through the alveoli, thus preventing atelectasis. 2. The derivative irritation of the cuticle causes hyperæmia, papules, and sometimes shedding of the epidermis. 3. The air surrounding the child should be kept moist, and to aid this a tea-kettle with steam or a spray apparatus should add moisture to the water, which constantly evaporates, owing to the heat beneath the cold application.

Hot Poultices.—The general use of hot poultices for the treatment of pneumonia, as was customary years ago, has been abandoned. The hot poultices may produce a local hyperæmia and affect in this manner the vessels of the lungs, but they help to maintain the fever, and there is always the danger of an exposure when they are removed.

The Oil-silk Jacket.—Properly made, this will be much more beneficial in the catarrhal pneumonia of children.

Elimination.—The use of calomel has already been mentioned, to cleanse the gastro-intestinal tract and to prevent constipation. In this same manner it is extremely necessary to give children large quantities of water, so that the action of the kidneys will be stimulated thereby. One of the best drugs to use as a diuretic for young children, and one that stimulates the heart's action as well, is coffee, properly sweetened and with a drop of milk added.

Antipneumococcus Serum.—This matter is still in its infancy, although it has been before the profession for several years. It is still in its experimental stage. Very interesting reports can be found in following the studies of Klemperer, of Berlin, and others. They used the products of the *Micrococcus lanceolatus* for an injection

into animals, and produced immunity to infection by these same organisms. The same organisms, however, remained present in an unchanged form; in other words, they caused a development of antitoxine in the tissues, which enabled the animals to resist the toxine of the germs. When the toxine was heated to 106° F., the immunity conferred was found to be greatly increased over that induced by injections made at a lower temperature. Klemperer asserts that the development of crisis in croupous pneumonia occurs at a time "when the body has produced sufficient antitoxine to antidote the toxine." Thus he states, which is very true and seems plausible, that when a crisis occurs in the course of a pneumonia as early as the third or fourth day, it merely shows that the body has generated enough antitoxine to antidote the toxine in the system. (Hobart A. Hare, *System of Practical Therapeutics*.)

Hygienic Treatment.—When there is a pneumonia, the first thing required is pure air. This cannot be insisted upon strongly enough. It is surprising to find that the majority of rooms in which patients are lying ill with croupous pneumonia usually have the windows and doors closed and the bedside surrounded by the anxious relatives, thus depriving the patients of much of the oxygen that might otherwise have been there. I am strongly in favor of giving oxygen for the immediate relief of dyspnoea or when there is intense cyanosis or labored breathing. The cheapest and most rapid method of giving oxygen is to "exclude all visitors but the nurse, and by cautiously opening the windows, screening the patient, to prevent chilling the surface."

In that form of catarrhal pneumonia in which dyspnoea and cyanosis become very manifest, there can be no doubt that life can be saved by the alternate use of the hot and cold douche, or the hot and cold bath. The child can be stripped and lifted from its bed, and immersed in a tub of water of a temperature of 100° to 105° F. This will produce a distinct irritation of the skin without doing it any damage; after a few moments, when the child is accustomed to this high temperature, it should be placed in a tub of cold water at a temperature of 70° F. In a few seconds it can be removed from this cold water, and again immersed in the hot. These powerful alternate stimulations of the peripheral sensory nerves cause wide dilatation of the peripheral capillaries, so that the surface of the child's body, which had been marbled or possibly mottled in appearance, becomes evenly red, and sometimes distinctly hyperæmic. As soon as this cutaneous hyperæmia develops, the evidences of engorgement of the respiratory organs and of labor on the part of the heart often disappear. This form of treatment is valuable not only in catarrhal pneumonia, but when there is distinct evidence of heart failure. The child should not be permitted to remain long enough in the cold water to be chilled, or in the hot water long enough to have its temperature raised, but each bath should be given quickly, and the child while in the water

should be briskly rubbed. This is a very important point, and one on which Baruch insists. These alternate hot and cold applications will not only relieve the engorged and laboring circulatory system, but will frequently cause a violent fit of coughing by this direct stimulation, thus cleansing the bronchial tubes of secretions accumulated therein. If the child is exceedingly weak, a few drops of Hoffmann's anodyne, five to ten drops in a teaspoonful of water, may be given before each bath. The frequency of the baths should depend on their indication, although several hours should be permitted to elapse before repeating them.

Drug Treatment.—It is a good plan to try to relieve the cough by giving small doses of codeine, one tenth of a grain every two or three hours, to try to induce sleep at the same time. Rest is most valuable to restore a child's strength, and I place rest along with fresh air, and, last but not least, supporting strength with food, as the three most important indications for treatment.

Feeding.—The most important point to be remembered in the course of the treatment of a pneumonia is to feed the patient. Thus, we must remember that, unless we sustain life with food, all drug treatment, all the reduction of temperature, will prove futile. If the appetite is subnormal, and a child will refuse food, then the choice, if it is a breast-fed baby, of drawing off the breast milk with the aid of a breast pump and feeding it through a funnel with the aid of a catheter must be considered. If vomiting is provoked, or the stomach will not retain food, owing to nausea and vomiting from severe fits of coughing, then the addition of some pancreatin and soda must be considered, and the child fed *per rectum* for a short time, at intervals of three or four hours. For older children, the yolk of an egg made into an emulsion, with some starch water added and some table salt, may be injected into the rectum as a temporary means of sustaining life, if the child refuses food by the mouth. To children who will take food, seltzer and milk is very grateful; concentrated beef juice or freshly expressed steak juice or the white of a raw egg added to water as a means of quenching thirst and nourishing the body must be considered. Soups made from beef or chicken or veal or mutton, with the addition of a cereal, are very good, if frequently administered, to give strength and sustain life. The physician who strengthens his patient by the administration of food will be most successful.

The Use of Stimulants.—The use of coffee has already been mentioned as one of the most valuable adjuvants in the course of the treatment of a pneumonia in children. So also has the use of Hoffmann's anodyne been mentioned as a means of stimulating the heart's action when a bath is to be given. My general rule has been to oil the machinery of the body in both catarrhal and lobar pneumonia by giving whiskey in small but repeated doses, just as we would give it in the course of any other toxæmia—for example, in diphtheria.

The dose required depends on the individual susceptibility or on the individual tolerance of this drug. If the pulse is carefully watched for several hours while we are administering alcohol, we can at once see what effect is being produced, and tell whether to increase or decrease the quantity. To order alcoholic stimulation haphazard is wrong, and it should not be left to the judgment of the nurse, much less to the discretion of the family, but the physician must order specific doses, and then increase or decrease the dose, taking the pulse and the other symptoms as a guide.

To recapitulate: When fever begins, give one-drop doses of aconite, repeated every hour, with or without fresh spiritus Mindereri, of the latter half-teaspoonful doses every hour until a general diaphoresis is produced.

Give calomel until a liquid green stool is produced; it will not only exert a hydragogue effect, but will also stimulate the flow of bile and the action of the kidneys. This is extremely important in view of a possible complication of nephritis.

Remember that water will carry off toxic products through the gastro-intestinal tract and also stimulate the flow of urine; it is also valuable to aid in producing diaphoresis and will be very grateful while fever is high. Therefore give water *ad libitum*.

Children cough and invariably swallow their expectorated matter. It is important to remember this, and give an occasional dose of calomel or castor oil. This so-called eliminative plan of treatment must be carried out throughout the whole course of treatment.

Antipyretics of the coal-tar series are, one and all, cardiac depressants, hence it is advisable to give them, if at all, with some stimulant, such as musk or camphor. I have made it a rule not to give antipyretic drug treatment at all, but to rely entirely on the cold pack, and, if the temperature gives rise to nervous symptoms or cerebral symptoms, such as convulsions or stupor or delirium, the tub bath will be found advantageous. The tub bath is to be given tepid as a full bath, the temperature to be 90° F. and gradually cooled to 70° F. by the addition of cold water or a piece of ice. The duration of the bath will depend on the amount of shock produced, but usually the bath need not be prolonged for more than from three to five minutes. Vigorous rubbing of the body while the child is in the bath will stimulate the circulation and prevent collapse. In very young and delicate infants it is advisable to give a few drops of Hoffmann's anodyne immediately before giving the bath.

A mustard foot bath will invariably stimulate the circulation and promote diaphoresis, and in this manner lower the temperature. The mustard best to be used is *pulvis sinapis nigri*, known in commerce as German mustard. It is best used by sewing about an ounce into a small bag made of cheese cloth, immersing this bag a few minutes before placing the child in the tub, and adding enough water to make a full bath covering the feet and ankles to the knees. The duration of the bath is to be

about two minutes. Severe local hyperæmia will be produced thereby.

Intense dyspnoea will best be relieved by applying dry cups over the thorax, three on each side anteriorly and posteriorly, to be repeated in a few hours if relief has been afforded thereby.

Oxygen can best be obtained by proper ventilation. This should consist in excluding all persons having no active business in the management of the case, opening the windows, screening the patient from draughts, and enforcing absolute quiet. Induce sleep by Nature's methods unless severe symptoms demand treatment, then, and then only, give codeine. I regard this latter drug as safe, in small doses, one tenth of a grain, to be repeated in an hour or two if no effect has been produced. The latter dose is for a child one year old. Older children can be given more in proportion; younger children one half the dose or one twentieth of a grain.

Where a toxæmic condition exists we must stimulate. Hence I invariably give some good Tokay wine or some good whiskey properly diluted. This is given to prevent collapse and heart failure, which would mean serious trouble.

Lastly, the sheet anchor of our treatment should be to feed our patient and thus try to sustain life until this acute disease terminates. Milk, to which a small quantity of whiskey is added, will be well borne. Good soups, with or without cereals like hominy or sago or farina, will prove useful. Besides, the nutrient qualities of egg albumen should not be forgotten. The raw white of an egg, beaten with some sugar and a few drops of whiskey, will serve a good purpose. If the pulse and heart do not need stimulation, egg albumen, alone or added to milk, will prove very useful.

65 EAST NINETIETH STREET.

PERIPHERAL "ANÆSTHESIA-PARALYSIS"—
REPORT OF AN UNUSUAL CASE OF BILATERAL BRACHIAL PARALYSIS OCCURRING DURING NARCOSIS (FOR APPENDICITIS).

BY WALTER M. BRICKNER, B. S., M. D.,

NEW YORK,

ASSISTANT SURGEON, MT. SINAI HOSPITAL DISPENSARY; ASSISTANT PATHOLOGIST, MONTEFIORE HOME.

PARALYSIS of an arm or of the muscles supplied by one or more nerves of an arm, appearing after the administration of a general anæsthetic ("anæsthesia-paralysis"), is fortunately not common, but cases have occurred in the experience of many surgeons, and several have been reported by Biedinger (1), Kron (2), Garrigues (3), Braun (4), Angelesca (5), Decroly (6), Krumm (7), Mally (8), Plæzek (9), Vantrien (10), Nucl (11), Casse (12), Duval and Guillain (13), Erdmann (14), Hersman (15), Ingebraus (16), and others.

A thorough search of the literature reveals but four reported cases in which paralysis of both arms occurred during narcosis. Bernhardt's (17) was the first case: A woman—Laparotomy, lasting over an hour. During this time *the Trendelenburg position was employed and both arms were drawn forcibly upward and backward.* After operation there was noticed, on each side, paralysis of the infraspinatus, deltoid, biceps, brachialis anticus, supinatores longus and brevis, triceps, and pectoralis major; also hypæsthesia of the antero-external areas of both arms in the upper part. No reaction of degeneration. The patient was improving at the time of the report, two months later.

Braun (4) has reported a similar case: A woman—Resection of the pylorus. Operation lasted two hours. *Both arms were drawn strongly up above the head and tied together.* Immediately after the operation there was complete sensory and motor paralysis of both arms. Six days later, paralysis was limited to the triceps, biceps, brachialis anticus, deltoid, latissimus dorsi, supraspinatus, and infraspinatus of each side; there was also paresis in the trapezii, pectorales majores, flexors of the fingers, some extensors, interossei, and the muscles of the thenar and hypothenar eminences; the sensibility was diminished. At the time of death, fifteen weeks after operation, the symptoms had not entirely disappeared.

Mally (8) has described this interesting case: A feeble and cachectic man—Pylorectomy. *Trendelenburg position.* After recovery from narcosis there was complete paralysis of both arms. Improvement was prompt. On the fifth day the paralysis was confined to the deltoid, biceps, brachialis anticus, and supinator longus and supraspinatus of each side. Atrophy was marked by the fifteenth day. In the second month *arthritis developed in both shoulders, with resulting reflex paresis and atrophy of the deltoids.* All other muscles recovered completely in function and size.

Leszynsky (18) records the following case: Vaginal hysterectomy. *Trendelenburg position. A leg-holder was employed, the strap being fastened tightly over the left shoulder.* After operation there was paralysis of both arms, complete in the left. Three months later, paralysis persisted in the left bicipital group and supinators; there was paresis of the deltoids, the right bicipital group, and the supinators, and the left triceps, hand extensors, and shoulder rotators. Some atrophy. No objective sensory changes. Faradaic contractility lost in the affected muscles. Patient was improving at the time of the report.

Since the following case is but the fifth in literature, possesses some unique features, and impresses practical lessons, it is worthy of record:

John T., aged twenty-five years, a native of Ireland; clerk. Previous and family histories negative. No neuritic taint in patient or his family. No alcohol or other "habit." Patient is over six feet in height, of medium muscular development, and strong. On September

4, 1900, the writer operated upon him during a recurrent attack of appendicitis, removing the adherent organ through a "trap-door" (Kammerer) incision in the rectus sheath. The skin and deeper layers of the abdominal wall were entirely closed by sutures. The operation lasted a little over an hour. Chloroform was administered without the slightest trouble, by an experienced and cautious anæsthetist. There was no struggling or vomiting in the induction of the anæsthesia, and no untoward symptom during its maintenance. At no time was it necessary to exert pressure on the neck or jaw to push the latter forward, and the head was not turned from the median line. About one ounce of the anæsthetic was employed. The patient lay supine upon a flat metal and glass (cushioned) table. At first both arms were abducted by the anæsthetist and the hands drawn above the head; this was for a few minutes only. Then the right arm was held by a nurse at right angles to the body, the forearm at right angles to the arm; the left arm was continued in a position of abduction of about 130°. No extraneous pressure or undue traction was exercised. The patient was placed in bed in a natural position. On recovering from narcosis, both upper extremities were found completely paralyzed, except for extremely feeble movement in the fingers of the right hand. Loss of function in the *spinati* and *serrati magni* showed that some, at least, of the supraclavicular branches of each brachial plexus were involved. No pupillary or other signs of affection of the sympathetic communicating branches were noted, however, and the head movements were fairly good. Paralysis of the *pectorales*, *teres*, *subscapulares*, and *deltoides* indicated that, of the infraclavicular branches, the anterior thoracic, circumflex, and subscapular nerves were involved, as well as the longer cords. The hands and forearms were anæsthetic. There was no record of the extent of anæsthesia in the upper arms; no hyperæsthesiæ, paræsthesiæ, or pain; no R. D. Temperature had risen from 101° F. before operation to 102° F., but fell next day to 100° F., and soon reached normal. No vomiting that day.

Treatment by massage, passive movements, electricity, and strychnine sulphate (*per os*) was instituted at once. Contrary to expectation, each application of galvanism was followed by immediate marked and permanent improvement. After a few days, however, galvanism failed of result, and faradaic electricity only was continued. *September 17th.*—Wound healed *per primam*. The patient feels well; no pain or fever. Right arm much improved, left forearm muscles still almost completely paralytic. Faradaic reaction in the muscles of the left hand diminished somewhat, otherwise still nowhere any R. D. Anæsthesia in the right hand disappeared quickly; in the left hand disappearing slowly. *September 21st.*—Out of bed. Massage, faradaism, and strychnine maintained. Improvement continued steadily, and cure was complete in two months. No atrophy was appreciable.

This belongs to the second of the groups of postanæsthetic paralyzes, as arranged by Mally and adopted by subsequent writers, viz.: (a) Central (apoplectic); (b) peripheral; (c) hysterical; (d) reflex. The arguments advanced by Verhoogen (19) and by Casse (12) in favor of a specific action of chloroform in the production of a toxic neuritis are refuted by experience and by the opinions of other observers. At most, the part played by the anæsthetic in the production of these paralyzes

consists in the reduction of the muscular tone (resistance to pressure), and in the deprivation of the patient's ability to withdraw his arm from a vicious position. Peripheral "anæsthesia-paralyzes" are traumatic in origin. This traumatism may be in the nature of a stretching of the nerves, or of pressure upon them, direct or indirect (in this connection it is interesting to note a case of bilateral brachial paralysis in a hod-carrier, reported by von Rieder (20), or of both stretching and pressure. Bernhardt attributed the paralysis, when following strong abduction of the arms, to pressure on the brachial plexus between the clavicle and the transverse processes of the sixth and seventh cervical vertebræ, which view finds confirmation in the articles of Braun, Krumm, Hoedemaker (21), and Nonne (22). Budinger found the pressure exerted through arm abduction to exist between the clavicle and the first rib, as did also Kron and Krumm. Gaupp (23) emphasizes the importance of the rotation of the clavicle upon its long axis, in the production of pressure at this point. Sehrwald (24), in reporting a significant case of bilateral brachial paralysis occurring in a gymnast from swinging up a ladder hand over hand, points the analogy of that case to the paralysis occurring from superextension of the arms under narcosis. He likewise attributes it to pressure on the brachial plexus between the elevated clavicle and the first rib, but asserts that paralysis of the long thoracic nerve occurs by bruising of the plexus between the clavicle and the scalenus medius, in those cases in which the arm is superabducted (especially if the head is extended). Kron also regarded the scalenus medius as an occasional point of pressure. Pressure of the head of the humerus against the nerve trunks is considered a source of paralysis by Braun, Kron, and Bardenheuer (as sometimes demonstrated in shoulder luxations). Duval and Guilain, from their experimental and critical studies, deny the theory of pressure between the clavicle and the first rib. They attribute brachial palsies following dislocation, contusion, or abduction of the arm during narcosis, to stretching of the nerve-roots. Accordingly the paralytic symptoms vary in degree with the lesions in the latter, the fifth and sixth roots being most liable to suffer (Erb's paralysis). They also explain the less intensity of the sensory paralysis on anatomical grounds, and consider any predisposition to be anatomical rather than morbid.

None of the views above quoted seems entirely adequate to explain the case here reported. But whatever the exact anatomical explanation may be, the traumatic element is evident. The practical deductions as to the prevention of these always disagreeable and sometimes permanent sequelæ are even more obvious:

1. The care of the arms is as important a part of the anæsthetist's duty as is the administration of the narcotic. They should never be allowed to hang over the edge of the table. This position threatens the musculospiral nerves by pressure, and the entire plexus by stretching.

2. Rotation and superextension of the head should be exercised only while emergency requires it.

3. Prolonged pressure of any kind should be avoided, be it that of an assistant's hand or body, or that of a harness. When used, the shoulder strap of a leg-holder should pass over the tip of the shoulder, or over a large pad of cotton wool on the neck; or, best of all, should be held by an assistant (the anæsthetist can usually spare a hand to pull the strap up from the body from time to time). It should be remembered that this apparatus has occasionally caused paralysis in a leg, as in one of Garrigues's cases.

4. The common practice of drawing the arms alongside the head, however much it may contribute to the convenience of the anæsthetist and the comfort of the operator, is a bad one, and should not be tolerated. Remembering that in some of the cases reported (25) the arms were lying alongside the body during the operation, the safest rule to follow is to *avoid allowing either arm to remain for more than a few minutes in any one position, however innocent that position may appear to be.*

THE RELATION OF ARTERIAL CHANGES TO THE HEART.*

By BEVERLEY ROBINSON, M. D.,

NEW YORK.

IN instances in which arteriosclerosis becomes evident at an early age, the influence of heredity should not be ignored. It may be that the individual has arteries whose powers of resistance are originally below par. They are simply made up of poor material. They probably would not resist the ordinary wear and tear of life very long, even under the best conditions of habits and environment. Whenever the habits and environment are bad, the necessary breakdown comes at a premature period. It is not essential in these cases to discover any source of chronic intoxication, such as alcohol, lead, gout, or syphilis, so as to reach a plausible explanation of a result which we observe. Many times no doubt, with superficial or insufficient inquiry, we are inclined to regard continuous overwork of muscles as being the direct, efficient cause of arteriosclerosis. With a judgment more carefully formed, we are apt to find other causative factors involved. Imperfect assimilation of food, due to a too large or insufficient supply, to poor preparation of it, to irregular hours, to work undertaken too soon after the digestive process has begun, all these help to produce arteriosclerosis by changing both quantity and quality of blood in an abnormal manner. Of course renal disease may be only a secondary manifestation of arterial changes. It may be and frequently is obscurely present for a long while, and later we are obliged to admit it as an evident or probably causative factor in the case. We recognize, therefore, that beyond the poor structure of the vessels *de novo*, there may have been later unintelligent and reckless use of them, which is explanatory of their organic changes during youth or in manhood before middle age.

In the nodular form of arteriosclerosis aneurysmal dilatation is no uncommon sequence. This dilatation is apt to occur at an early period and before the spot locally weak has been strengthened by proliferative changes in the intima. In regard to senile changes, it must be emphasized, so as to avoid confusion, how relatively rare cases of cardiac hypertrophy are as compared with those which follow the diffuse form. This fact Councilman insisted upon in his able paper read before the Association of American Physicians in 1891.

He has also shown that the liver and kidneys may be atrophied with this same senile form of arterial degeneration. The diffuse form of arteriosclerosis is frequently found among middle-aged men and particularly those who are strong and vigorous. It is in this form that we encounter usually cardiac hypertrophy. Accompanying the hypertrophy we do not find fibrous myocarditis, as a rule, unless the coronary arteries are involved. If the

*Supplementary to a discussion before the Section in General Medicine of the New York Academy of Medicine, Tuesday evening, April 16, 1901.

latter condition prevails, it is quite common to note a sclerosed and incompetent state of the aortic valves. Under these circumstances the kidneys are also more or less contracted and hard in consequence of interstitial changes. The main essential change at this period, in the small arteries, is that of thickening owing to hyaline formation in the muscular coat. Later the muscular fibres of the media may become atrophied and even show fatty degeneration of cells. The capillaries, notably those of the glomeruli, become thickened from hyaline degeneration. In those instances in which the pulmonary artery is sclerosed we must also expect to find a certain degree of cardiac hypertrophy.

In many cases this condition extends generally to the veins. In mitral stenosis it is especially to be remarked that we have a sclerotic state of the pulmonary veins. The new tissue there deposited may undergo hyaline degeneration and calcification. The peripheral veins may become sclerosed without the arteries becoming involved in a similar change. High tension may exist very often in the arteries without any marked arterial changes. In these cases the tension is variable and sometimes disappears altogether, showing that it must depend upon accidental or passing conditions. Of course it may recur more or less frequently, depending upon the presence or return of the dynamic changes which may affect or produce it. When, however, high tension exists in a continuous, persistent manner, usually speaking, it is directly connected with the existence of arteriosclerosis. The slow, slanting pulse tracing is very indicative of high tension. In these tracings we find the line of ascent and descent not unlike, and there is notable absence of the dicrotic wave. During the interval between the pulse beats the artery remains full and firm to the touch, and it is very difficult at times partially to obliterate it by pressure. Here there may be confusion owing to the recurrent wave, which we should eliminate if possible, and particularly so because it is present with and characteristic of the pulse of low tension which is met with in the early stages of typhoid fever.

Clinically, I find some of the cases of cardiac insufficiency following hypertrophy due to arterial changes most interesting. Occasionally they are difficult of precise diagnosis, especially when they first present themselves to us and without an accurate previous history. They are often confounded with chronic valvular disease, and this is particularly the case where there is a pronounced blowing systolic murmur at the apex.

In the treatment of these cases, while it is often manifestly indicated for a while to give heart tonics and stimulants, such as strychnine, digitalis, and strophanthus, it is also wise to administer in moderate doses iodide of potassium, and for long periods with occasional interruptions. This we do to modify the sclerosed arteries and to influence favorably any degree of spasm which may be present locally or generally from time to time, and even in cases in which there is no reason to

suspect the presence of syphilis. In some instances of the most threatening heart failure in hypertrophic dilatation, I am confident of having saved life by local or general bloodletting. A few leeches to the præcordia will now and then work wonders where drugs are temporarily of no avail. Owing to the greater mental apprehension connected with venesection, it seems preferable in very nervous patients to avoid it, if at all practicable.

42 WEST THIRTY-SEVENTH STREET.

Therapeutical Notes.

A Diaphoretic Powder.—The *Gazette hebdomadaire de médecine et de chirurgie* for March 28th ascribes the following, from *Nouveaux remèdes*, to Von Graefe:

℞ Powdered camphor. . . from $\frac{3}{10}$ ths of a grain to $1\frac{1}{2}$ grains;
Powdered opium. " $\frac{1}{10}$ ths of a grain to $\frac{1}{2}$ a grain;
Potassium nitrate. " 3 grains to $4\frac{1}{2}$ grains;
Sugar. 112 grains.

M. For one powder. One powder to be taken in a cup of tea at bedtime.

The Treatment of Gonorrhœa by Hot Saline Solution.—Dr. Woodruff, according to the *Medical Press and Circular* for April 10th, recommends the use of injections of saline solution, as hot as can be borne, every two or three hours, and even, if possible, every hour. Dr. Woodruff finds no necessity, under this treatment, for the administration of medicines, by the mouth, and states that the average duration of the disease in a number of soldiers thus treated was ten or twelve days only.

An Inhalation for Bronchial or Pulmonary Affections.—*Journal des praticiens* for March 16th gives the following:

℞ Menthol. 1 part;
Eucalyptol. 1 "
Essence of thyme. 5 parts;
Essence of lavender. 5 "
Tincture of tolu. 10 "
Alcohol. 100 "

M. A teaspoonful to be added to a pint of hot water and the steam inhaled.

The "Normal Salt Solution."—There is some variation in the formulæ given by different writers. Dr. Charles A. L. Reed, in his new *Text-book of Gynæcology*, remarks that Locke has suggested the following formula and reported favorably upon it:

℞ Calcium chloride. $3\frac{3}{4}$ grains;
Potassium chloride. $1\frac{1}{2}$ grains;
Sodium chloride. $2\frac{1}{2}$ drachms;
Sterilized, distilled, or tap water,
enough to make. 1 quart.

M. The solution may be injected subcutaneously, into the intestine, or into a vein.

For Toothache.—*Gazette hebdomadaire de médecine et de chirurgie* for April 4th ascribes the following to Guillaumin:

℞ Crystallized carbolic acid, }
Menthol, }
Cocaine hydrochloride, } equal parts.
Chloral, }
Guaicol, }

Triturate in a mortar. A pasty liquid is thus obtained, easy of employment, and both caustic and anæsthetic. The caustic action may be augmented by increasing the carbolic acid.

THE NEW YORK MEDICAL JOURNAL
62-68 West Broadway

NEW YORK, SATURDAY, APRIL 27, 1901.

BRITISH APPRECIATION OF OUR MILITARY HOSPITALS.

THOSE of us who remember the superb military hospitals of the civil war know that at that time the rest of the world could teach us nothing concerning the care of sick and wounded soldiers, but might, on the other hand, have copied our methods to its advantage—and did so, for that matter. We hardly expected, however, that the present excellence of our army medical service would soon be so thoroughly appreciated as it has been by the *British Medical Journal's* correspondent with the China expeditionary force, as shown in a letter from him published in that journal for April 13th. That he made his observations with no prejudiced eyes is plain from the following passage in his letter: "I am not one of those whose habit it is to see only faults in our own departments and virtues in others, but the picture of some of the equipment I saw in the American hospital in the 'Temple of Agriculture' is still before my eyes, and I reflect that, if any local community is anxious to start a museum, they could make an excellent beginning with one of our ancient pattern velvet-lined capital cases, with its old wooden-handled instruments."

The correspondent's remarks are founded mainly on what he saw one afternoon in the American hospital in the Temple of Agriculture in Peking, but he makes the general statement that "medical arrangements in the American army possess a far higher degree of importance than in our own." He goes on to say, not only that the hospitals are given the best sites available, as is assumed to be the case in the British army, but the amount of skilled labor supplied for employment under the direction of the chief medical officer is as unstinted as the funds placed at his disposal, and he quotes "combatant" officers as saying good-humoredly: "It's no use trying to

get a nail knocked in anywhere else until the hospital is finished." He does not approve of our rations as compared with those of the British soldier, but we will let him go on in his own words, as follows: "His (the American soldier's) diet on active service contains luxuries and delicacies the names of which are scarcely known in our Commissariat Department—personally, I think our Commissariat are to be congratulated, for the diet of our soldiers is, in my opinion, superior in nearly every way to that of the American army and more suited to the requirements of a campaign—but it is not till the American soldier goes to hospital that he is really in a position to appreciate how much his government loves him. I do not think it would be a serious exaggeration to say that the American Hospital in Peking could hold its own in every respect with most London hospitals. Bedsteads, bedside tables, and chairs brought from America, a 'diet kitchen' at the end of the ward, with an ample cooking range and a highly trained cook in a white apron and cap, whose life's business is cooking and who is not expected to do anything else. He is not an enlisted soldier, and he may not know one end of a rifle from another, but he can turn out any known delicacy that ever tempted the appetite of a worn-out patient. I lay stress on this, as indeed anyone would who saw those business-like 'diet kitchens' and cooks with a lavish supply of all the apparatus, materials, and paraphernalia that a *chef* could desire. The difficulty of supplying really good food to the sick on active service is a great one, but the American Government, by simply recognizing this fact and by making an extra outlay to meet the difficulty, in a large measure overcomes it."

The excellent training and efficiency of the men of the Hospital Corps excited the correspondent's admiration. "When," he says, "the work at Wei-Hai-Wei in the naval hospital became heavier than could be dealt with by the staff of the hospital, five of these Hospital Corps men were lent from the hospital ship *Maine*, and, to quote the words of a surgeon under whom they worked, 'everyone was astounded at their wonderful training.'" The high pay of these men is to him the explanation of their great efficiency, but his opinion is that "this expenditure is economy in the long run," and, while he found the hospital supplies "not less than lavish," he saw nothing that could fairly be called excessive. Indeed, he cannot believe, he declares, that the general superiority of the American over the British army medical service is due to anything else than the freer expenditure by the American Government. We hope Congress will take this

view of the matter and never again be niggardly in furnishing an adequate force of medical officers and abundant supplies for the comfort and recovery of the sick and wounded. For its size, our little band of regulars is the finest army in the world. We are much mistaken if the people will knowingly allow it to be crippled by anything that can be avoided; least of all will they tolerate anything but the best that can be had in the way of care for the "boys in blue" when they are sick or wounded. Nothing should more strengthen Surgeon-General Sternberg's hands than this appreciative British picture of the operation of his service.

A NEW JOURNAL OF PREVENTIVE MEDICINE.

It is to England that we have long been accustomed to look for solid progress in sanitary science, and from that country there now comes a publication destined, we believe, to accomplish much in furthering our advances in preventive medicine. We have reference to the new *Journal of Hygiene*, a quarterly, the first number of which, dated January, 1901, has apparently been somewhat delayed in its appearance, as is apt to be the case with new periodicals of such a high class, for it is only within the last three weeks that it has reached us. It is a fine example of the scientific journal of the present day, ranking, we should say, with our own *Journal of Experimental Medicine*. The field to be covered by the new English journal, as defined in the introduction, includes physics, chemistry, physiology, pathology, bacteriology, parasitology, and epidemiology in so far as they relate to hygiene and preventive medicine.

The new journal is edited by Dr. George H. F. Nuttall, Dr. John S. Haldane, and Dr. Arthur Newsholme, and issued by the University Press, Cambridge. Dr. Nuttall, as few if any of our readers need to be told, was until lately an associate in hygiene in the Johns Hopkins University. By his accession to the faculty of the University of Cambridge, in which he is now lecturer in bacteriology and preventive medicine, Great Britain has gained what we have lost—his personal, word-of-mouth teaching—but his writings will still reach us freely, largely, it is to be expected, in the pages of his new journal. Dr. Haldane is lecturer in physiology in the University of Oxford. Dr. Newsholme is the medical officer of health of Brighton, and no doubt he will see to the substantiation of the following sentence in the introduction: "With a view to increasing the general usefulness of the *Journal of Hygiene*, we propose not to limit the

contributions entirely to reports of original observations and experiments, but to accept and encourage discussions of administrative and practical questions the importance of which is apt to be overlooked in scientific journals." In the list of collaborators we are pleased to note the names of a very large proportion representing the United States and Canada (one country from the medical profession's point of view)—no fewer than twenty-nine in a total of seventy-two.

THE SING SING "TUBERCULOSIS FACTORY."

THIS is what Mr. Charlton T. Lewis, speaking for the executive committee of the Prison Association of New York, of which he is the chairman, very properly calls the State prison at Sing Sing. He describes the prison as "shrouded in a chilling veil of dampness," and its cells as having never been penetrated by the purifying sunlight. Rating the air space for each inmate in the best modern prisons at a thousand cubic feet, he tells us that in the Sing Sing prison it amounts to only a hundred and fifty under the best of conditions, and with the "doubling up" frequently required by its over-populated state to not more than seventy-five—in other words, to less than a tenth of what it ought to be. The community would call it cruel to inoculate a convict with tuberculous disease; yet that is what the great and wealthy State of New York is constantly doing, and has been doing for over seventy years, by condemning men and women to years of confinement in so insanitary an abode as this prison. Some of them endure it, to be sure, but those of them who have the slightest susceptibility to pulmonary consumption are well-nigh sure to contract it—more than that, to spread it broadcast through the community after their release.

Mr. Lewis speaks none too pointedly of the incongruity of establishing State institutions for the care of consumptives and endeavoring to limit the spread of consumption by punishing persons for spitting in public conveyances, while at the same time the State maintains this hot-bed of infection in Sing Sing. It has been shown over and over again that no amount of money expended on the Sing Sing buildings could remedy their terrible destructiveness to health and life. There is but one thing to be done, and that is to raze them to the ground and build a new prison elsewhere, for the very ground itself must be tainted, to say nothing of the poisonous odors consequent on the "backing up" of sewage. Perhaps the ground may in time be reclaimed by

some germicidal agency having the potency of fire, and thus made suitable for business or dwelling houses; but meantime another prison must be provided.

The right of society to confine criminals, whether for punitive or for correctional purposes, cannot be gainsaid. It is none the less true, however, that cruel and unusual punishments are unconstitutional as well as repugnant to the public conscience. Many of the crimes for which persons are incarcerated at Sing Sing are not capital, as Mr. Lewis urges; yet the State virtually treats their perpetrators as if they were when it immures them in such an out-of-date dungeon. Sing Sing prison is an anachronism; it must go.

"DEMI-VIRGINITY."

THE *Journal de médecine de Paris* for December 9, 1900, comments on a murder trial in which a distinguished French medico-legal expert, having examined the hands of three accused persons to ascertain whether they were capable of having caused the lesions that resulted in death by strangulation, let fall the extraordinary statement that "he had also minutely examined M. L—, a demi-virgin of a kind (*demi-vierge en quelque sorte*) at the time of her first arrest, but who was no longer such when imprisoned for the second time." Well may our contemporary exclaim: "Our confrère of Nîmes should please inform us what are the signs which establish in legal medicine the state of demi-virginity. It would have appeared to us," continues the *Journal*, "already very difficult to affirm the existence of complete virginity, especially before a court of justice; but we have made progress, since virginal membranes may be measured by halves, quarters, and wholes." Our contemporary regards this matter as an evidence of the influence of literature upon science. There is literature and literature. But, then, this happened in France.

THE PHYSIOLOGICAL ACTION OF WINE.

ACCORDING to the *Chemist and Druggist* for April 6th, M. Roos has reported to the Paris Academy of Sciences his experiments made upon six pairs of guinea-pigs, four pairs of which were given wine daily, while the others were provided with the usual food only. M. Roos finds that in regard to endurance, weight, strength, number of offspring, and longevity, the tests were altogether in favor of the wine-fed animals. We cannot help feeling that those who are ardent in their crusade against the evil effects of alcoholism make a grave error in including light wines under their ban. We believe light white and red wines of the claret and hock order, if pure and unfortified, to be harmless in all cases, save perhaps a few isolated individuals, beneficial in very many, and practically indispensable in some, especially when taken with meals.

The general use of such wines as a dinner drink, if they can be provided as cheaply as on the continent of Europe, and of as light a character—all the domestic wines produced at present are, either naturally or in consequence of sophistication, too alcoholic and "heady"—should, in our opinion, rather be hailed as an auxiliary to the cause of temperance, than included in the crusade against alcoholism.

CRYOSCOPY IN THE PROGNOSIS OF TYPHOID FEVER.

OBSERVATIONS in cryoscopy as an aid in diagnosis and prognosis have been not a few of late, but we do not recall a more serviceable short article on the subject than we find in the form of an editorial in the March number of the *Medical Age*, of Detroit, a journal, by the way, in which we always expect to find something exceptionally good. The writer in this instance summarizes Waldvogel's researches in twenty-four cases of typhoid fever. It appears that the normal freezing-point of the serum is 0.56° . The highest points observed by Waldvogel, 1.68° and 1.28° , were in two convalescents; the lowest, 0.65° , 0.63° , and 0.54° , in three fatal cases. The rise of the freezing-point was at first attributed by Waldvogel to uræmia, but further investigation led him to infer that in this he was incorrect, and he now looks upon the rise as an accompaniment of the production of an antitoxine. The inference is that, if the rise fails to occur, the organism is unequal to the production of the antidotal principle, and consequently a fatal issue is very much to be feared.

THE PATHOLOGICAL INSTITUTE OF NEW YORK STATE HOSPITALS.

WE are sorry to learn by an article that appeared in the *Evening Post* for April 20th that there are persons who are still seeking to make it appear that the director of the institute, Dr. Ira Van Gieson, is diverting its work from what they are pleased to lay down as its chief if not only legitimate field, and are agitating, therefore, for his removal. We have heretofore deprecated this sort of detraction, and expressed our confidence in Dr. Van Gieson's judgment as to what the institute was most called upon to do. Physicians in general take the same view of the matter, and we still hope that the opposition to the institute's scientific work may soon be silenced.

THE OXYTOCIC ACTION OF LUMBAR INJECTIONS OF COCAINE.

NOT the least interesting point connected with the endometrial use of cocaine is that of its alleged action on the uterus. Doléris, of Paris (*Klinisch-therapeutische Wochenschrift*, 1901, No. 8; *Wiener medicinische Blätter*, March 14th), asserts that, apart from full-term

parturition or the justifiable induction of premature labor, it is inadmissible, since it is prone to set up uterine contractions.

THE QUININE TREATMENT OF TYPHOID FEVER.

EVIDENTLY quinine as an antipyretic has not yet been wholly overslaughed by the new synthetics. In the January number of *Therapie der Gegenwart* (*Centralblatt für innere Medicin*, March 30th) W. Erb sets forth its advantages, and in the February number C. Binz assures us that he has seen no reason to recede from his advocacy of the quinine treatment of typhoid fever, now of more than thirty years' standing. Erb thinks that it not only mitigates the disease, but also shortens its duration.

"HEAD-KNOCKING" IN CHILDREN FROM A MEDICO-LEGAL POINT OF VIEW.

THE phenomenon of "head-knocking" in rickety children, which appears to be more common in England than in the United States, consists in the child's knocking its head, apparently with a good deal of satisfaction, with considerable force against the floor or some hard object. No explanation appears to be forthcoming of this peculiar phenomenon. Dr. Aldrich (*Annals of Gynecology and Pædiatry*, March) reports such a case in a child thirteen months old, which occurred under his own observation in the Cleveland General Hospital. The child was neglected and cachectic, and its face, head, and neck were covered with contusions. The doubt entertained by the physicians of the truth of the mother's statement that the injuries were self-inflicted was dispelled in hospital by the child's beating its head against the cradle rail, and when this was prevented, by its battering its head with its hands. Dr. Aldrich very pertinently points out that "had the child been dead or too ill to longer carry out its self-chastisement before death, no jury could have been convinced that those who were her caretakers were not responsible for the bruises and death." More light on this subject is clearly desirable.

THE HOSPITALS OF JAPAN.

WE are indebted to Dr. Edward C. Register, one of the editors of the *Charlotte Medical Journal*, for a copy, in pamphlet form, of an article of his, entitled *The Hospitals of Japan*, which was published in the December number of that journal. Dr. Register notes the great prevalence of tuberculous disease in Japan, and accounts for it by the habits of the people, especially in continually exposing themselves to cold and dampness in their dwelling houses. It seems that there are only ten hospitals in all Japan, and the Imperial University Hospital in Tokyo is as large as all the nine others together.

News Items.

Society Meetings for the Coming Week:

- TUESDAY, April 30th: Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).
- WEDNESDAY, May 1st: New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.
- THURSDAY, May 2d: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.
- FRIDAY, May 3d: Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.
- SATURDAY, May 4th: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending April 20, 1901:

DISEASES.	Week end'g Apr. 13		Week end'g Apr. 20	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	29	14	22	13
Scarlet Fever.....	619	50	729	37
Cerebro-spinal meningitis.	0	7	0	4
Measles.....	348	10	280	10
Diphtheria and croup.....	285	47	272	45
Small-pox.....	44	11	38	10
Tuberculosis.....	253	173	248	185

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from April 13 to April 20, 1901:

- AMES, ROGER P., Acting Assistant Surgeon, is granted leave of absence for two months, with permission to go beyond sea.
- EBER, ALBERT H., Captain and Assistant Surgeon, upon the expiration of his leave of absence, will proceed from St. Clair, Michigan, to San Francisco, for transportation to Manila.
- KILBOURNE, HENRY S., Major and Surgeon, is detailed as a member of the board appointed to meet at the United States General Hospital, Presidio of San Francisco, for the examination of candidates for admission to the Medical Corps of the Army, vice BENJAMIN F. POPE, Lieutenant-Colonel and Deputy Surgeon-General, relieved.
- MADARA, JAMES W., Captain and Assistant Surgeon, United States Volunteers, will proceed to San Francisco, for transportation to Manila.
- MEARNS, EDGAR A., Major and Surgeon. The sick leave granted him is extended six months.
- POINTDEXTER, JEFFERSON D., Captain and Assistant Surgeon, having been examined for promotion and found physically disqualified for the duties of a major and surgeon, by reason of disability incident to the service, his retirement from active service as a major is announced.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending April 20, 1901:

- ALFRED, A., Passed Assistant Surgeon. Ordered to duty with the Marine Brigade, Cavite, Philippine Islands.
- ANDERSON, F., Surgeon. Ordered to the Naval Dispensary.
- ARNOLD, F. W., Surgeon. Ordered from the *New Orleans* to Olongapo Station, Philippine Islands.
- BLACKWOOD, N. J., Passed Assistant Surgeon. Detached

- from the Naval Hospital, Philadelphia, and ordered to the *Alliance*.
- CURL, H. C., Assistant Surgeon. Detached from the *Castine* and ordered to the Naval Station, Cavite, Philippine Islands.
- GARDNER, J. E., Surgeon. Detached from the Marine Recruiting Rendezvous, Boston, and ordered to the Naval Hospital, Cavite, Philippine Islands.
- GROW, E. J., Assistant Surgeon. Detached from the *Glacier* and ordered to the *Isla de Luzon*.
- MORRIS, L., Passed Assistant Surgeon. Detached from the Naval Academy, Annapolis, and ordered to the Naval Hospital, Philadelphia.
- PECK, A. E., Assistant Surgeon. Ordered to the *Pensacola*.
- STEEP, J., Assistant Surgeon. Detached from duty with the First Regiment of Marines and ordered to the *Castine*.
- STONE, E. P., Surgeon. Detached from the Naval Dispensary, Washington, and ordered to the *Dolphin*.
- URIE, J. F., Surgeon. Detached from the *Dolphin* and ordered to the Marine Recruiting Rendezvous, Boston.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending April 18, 1901:

- BALLARD, J. C., Acting Assistant Surgeon. The leave of absence granted him by the Bureau letter of February 4th, is amended to read, six days from April 23d.
- BERRY, T. D., Assistant Surgeon. Granted leave of absence for thirty days from May 2d.
- BLUE, RUPERT, Passed Assistant Surgeon. Directed to proceed to San Francisco and report to Surgeon J. H. WHITE for special temporary duty.
- CORPUT, G. H., Assistant Surgeon. Directed to proceed to San Francisco and report to Surgeon J. H. WHITE for special temporary duty.
- FOSTER, M. H., Assistant Surgeon. Two days of the leave of absence granted him by the Bureau letter of March 11th is revoked.
- GEDDINGS, H. D., Passed Assistant Surgeon. Directed to proceed to Buffalo for special temporary duty in connection with the installation of the Marine-Hospital Service exhibit at the Pan-American Exposition.
- GOLDSBOROUGH, B. W., Acting Assistant Surgeon. Granted leave of absence for seven days.
- HALL, L. P., Hospital Steward. Directed to proceed to Boston and report to the Medical Officer in command for duty and assignment to quarters.
- MCGINNIS, R. H., Acting Assistant Surgeon. Directed to proceed to St. Augustine, Florida, for special temporary duty.
- MOORE, DUNLOP, Assistant Surgeon. Relieved from duty at Port Townsend Quarantine, and directed to proceed to San Francisco and report to Surgeon J. H. WHITE for special temporary duty.
- PARKER, H. B., Assistant Surgeon. Directed to proceed to San Francisco and report to Surgeon J. H. WHITE for special temporary duty.
- RICHARDSON, S. W., Hospital Steward. Directed to proceed to Buffalo and report to Passed Assistant Surgeon H. D. GEDDINGS for special temporary duty.
- VAUGHAN, G. T., Surgeon. Reassigned to duty in the Marine-Hospital Bureau.

Appointment.

LOUIS P. HALL, of New York, appointed junior hospital steward in the United States Marine-Hospital Service.

The Annual Meeting of the British Medical Association this year will be held at Cheltenham from Tuesday to Friday, July 30th to August 2d, inclusive.

New Addition to the Rush Medical College.—Work has been begun on a seven-story brick addition to the Rush Medical College, in Chicago. The edifice is expected to be finished for the fall term. The estimated cost is \$100,000.

Dr. Kinyoun, Quarantine Officer at San Francisco, Transferred.—Dr. John J. Kinyoun, of the U. S. Ma-

rine-Hospital Service, has been transferred from San Francisco to St. Paul, Minn., and Dr. Carmichael, Federal quarantine officer at Honolulu, has been appointed his successor on the Pacific coast. The change will take effect on May 1st.

A Practical Course in Bacteriology will be given at the University and Bellevue Medical College on alternate days beginning on Monday, April 29th, and concluding on May 29th. The courses will be under the direction of Dr. W. H. Park, professor of bacteriology and hygiene, assisted by Dr. Robert J. Wilson, Dr. H. H. Brooks, and Dr. R. H. Bebb, assistants in bacteriology.

An International Central Bureau for Combating Tuberculosis has been formed at the instance of the central committee of the German association for tuberculosis sanitariums, as a consequence of the correspondence carried on with foreign organizations in connection with the tuberculosis congress. The headquarters of the bureau have been established at 2 Wilhelmplatz, Berlin W., Germany.

Christian Scientists must not Practise in Georgia.—A judge of the Superior Court of Georgia recently denied the application for a charter for "The Atlanta Institute of Christian Science" on the ground that Christian Scientists cannot practise their treatment of diseases in Georgia without having been regularly graduated in medicine or having passed an examination before the medical examining board like other physicians. Judge Lumpkin holds that, according to the decision of a case in the Supreme Court of Nebraska, Christian Science is the practice of medicine.

A Compromise with Wisconsin Osteopaths.—The contest over the passage of an osteopathist bill has been settled by compromise. At a meeting of the representatives of the osteopaths and the regular physicians and members of the Committee on Public Health at Madison an agreement was reached that the medical bill shall be amended so that one of the members of the board shall be an osteopath and shall be appointed within thirty days of the passage of the bill. All osteopaths who are regular graduates of reputable colleges and who have practised in the State prior to March 1, 1901, shall be granted a license. All others shall take an examination before the board in all branches of medicine except materia medica, therapeutics, and surgery. All persons licensed must be graduates of reputable colleges of osteopathy. After 1903 only osteopathic colleges that conform with the same studies now taught in medical colleges shall be recognized by the board. Four-year courses shall be required.

San Francisco's Chinatown Cleansed.—Acting upon the authority of the State Board of Health and the Board of Health of San Francisco, an army of disinfectors and sanitary agents recently invaded Chinatown, under the personal direction of Dr. White, of the U. S. Marine-Hospital Corps, and proceeded to give the dens and dives the first thorough cleaning they have perhaps ever had. The filth and squalor of some of the underground dens was beyond description, but every nook and corner of Chinatown was fumigated and disinfected until there was not the remotest possibility of a disease germ remaining. In future Chinatown will have to live in strict accordance with the sanitary laws. There will be no

more throwing of offal into the streets and alleys, but everything will be carefully kept in iron casks and burned on certain days. There will also be a detention hospital and a morgue established in Chinatown, as well as a dispensary. The State Board of Health has an appropriation of \$25,000 to expend in the work, and the Board of Health of San Francisco will cooperate with the State authorities and also expend a considerable sum in addition.

Changes of Address.—Dr. John Aspell, to No. 105 Madison Avenue, New York; Dr. M. Chertler, to No. 50 St. Mark's Place, New York; Dr. J. A. Hofheimer, to No. 123 West One Hundred and Twenty-sixth Street, New York; Dr. W. J. Pulley, to No. 945 Madison Avenue, New York; Dr. Charles Cook Ransom, to No. 66 West Forty-ninth Street, New York.

The Medical Association of Dutchess (N. Y.) County has been organized with the following officers: President, Dr. I. D. LeRoy; vice-president, Dr. E. Barnes; secretary, Dr. J. A. Atwood, and treasurer, Dr. M. T. Pultz.

The St. Louis District Medical Society held its fifth semi-annual meeting on April 11th. Dr. F. J. Tainter was re-elected president and Dr. J. C. Murphy chosen permanent secretary. The next meeting will be held in St. Charles.

The Society of Medical Jurisprudence held its eighteenth annual dinner at the Waldorf-Astoria, New York, on April 20th. Among the speakers were Father Thomas J. Ducey, Dr. William M. Polk, Charles W. Dayton, E. B. Hinsdale, Theodore Sutro, Frank Ferguson, the president, and Justice William J. Gaynor.

The Cumberland County (Pa.) Medical Society.—The annual meeting of the Cumberland County (Pa.) Medical Society was held in Bridgeton on April 11th, and these officers elected: President, Dr. L. L. Hand; vice-president, Dr. G. E. Day; secretary, Dr. J. C. Applegate, and treasurer, Dr. Joseph Tomlinson.

The Bartholomew County (Ind.) Medical Society.—The following officers have been elected by the Bartholomew County (Ind.) Medical Society: President, Dr. Georg O. Cosby; vice-president, Dr. Elmer U. Wood; secretary and treasurer, Dr. J. L. Morris; board of censors, Dr. R. E. Holder, Dr. A. P. Roope and Dr. George T. MacCoy.

The Medical Society of the State of North Carolina will meet in Durham on May 21st, 22d and 23d, under the presidency of Dr. Julian M. Baker, of Tarboro. The oration will be delivered by Dr. Earle Grady, of Tryon. The essay will be read by Dr. R. S. Primrose, of Newbern. Dr. A. G. Carr, of Durham, is chairman of the committee of arrangements.

The Alabama Medical Association, at its session in Selma, on April 18th, elected the following officers for the ensuing year: Dr. E. L. Marechal, Mobile, president; Dr. W. T. Bride, Madison, senior vice-president; Dr. M. B. Cameron, Sumpterville, junior vice-president; Dr. G. P. Waller, Montgomery, secretary; Dr. H. G. Perry, Greensboro, treasurer, and Dr. E. B. Ward, Selma, orator.

The Milwaukee (Wis.) Medical Society held its semi-monthly meeting on April 9th. The feature of the evening was a paper by Dr. Paul Thorndyke, of Boston, on Prostatic Surgery, which was discussed by Dr. A. J. Burgess, Dr. Solon Marks, Dr. H. A. Sifton, Dr. Ralph Chandler and Dr. O. C. Thienhaus. Dr. W. C. Bennett and Dr. H. V. Wurdemann also read papers.

The Section on Surgery of the New York Academy of Medicine will meet at the Academy on May 2d. Dr. Howard Lilienthal will present a paper on The Clinical Aspects of Acute Intestinal Obstruction, and special divisions of the subject will be discussed by Dr. B. Farquhar Curtis, Dr. George E. Brewer, Dr. Charles L. Gibson, Dr. Morris Manges, Dr. Henry Koplík and others.

The Louisiana State Medical Society.—The twenty-second annual meeting of the Louisiana State Medical Society was held at the medical department of Tulane University, New Orleans, on April 18th, 19th and 20th. Dr. F. W. Parham is the president and Dr. Herman B. Gessner recording secretary. Dr. Isidore Dyer is chairman of the committee of arrangements.

The New York State Eclectic Medical Society has elected the following officers: President, Dr. F. P. Sinclair, of Lysander, N. Y.; first vice-president, Dr. T. W. Powers, of New York; second vice-president, Dr. Henry Stoesser, of Brooklyn; third vice-president, Dr. E. H. King, of Saratoga; recording secretary, Dr. S. A. Hardy, of New York; corresponding secretary, Dr. G. W. Boscowitz, of New York; treasurer, Dr. L. E. Horton, of Avoca.

The Lebanon County (Pa.) Medical Society.—At the meeting of the Lebanon County (Pa.) Medical Society recently the following officers were elected: President, Dr. John Light, Schaefferstown; vice-presidents, Dr. W. R. Roedel, Lebanon, and Dr. H. W. Gass, Mt. Etna; secretary, Dr. C. M. Strickler, Lebanon, re-elected; treasurer, Dr. C. L. Miller, Lebanon; censor, Dr. H. H. Roedel, Lebanon, and medical and surgical reporter, Dr. S. P. Heilman, Heilman Dale.

The State Medical Association of South Carolina met recently at Florence. The following officers were elected: President, Dr. T. G. Croft, Aiken; first vice-president, Dr. C. B. Earle, Greenville; second vice-president, Dr. W. P. Timmerman, Edgefield; third vice-president, Dr. J. T. Darwin, Blacksburg; corresponding secretary, Dr. William Weston, Columbia; recording secretary, Dr. T. P. Whaley, Charleston; treasurer, Dr. B. E. Baker, Charleston.

The Florida Medical Association elected the following officers at its recent meeting in Jacksonville: President, Dr. J. A. Wakefield, of Jacksonville; first vice-president, Dr. M. D. Blocker, of Chattahoochie; second vice-president, Dr. George E. Welch, of Palatka. The secretary, Dr. J. D. Fernandez, and the librarian, Dr. E. N. Trill, hold over for another year. Tampa was selected as the next place of meeting.

The Annual Dinner of the Harlem Medical Association was held on April 17th at the Hotel Majestic, New York. Twenty-four tables were clustered around the speakers' table, at which were seated a hundred physicians, their wives and invited guests. A vaudeville per-

formance and informal dance followed the dinner. The speakers were Dr. Louis J. Ladinski, Dr. John A. Wyeth, Dr. Montrose R. Richard, Dr. Emil Mayer and the Rev. George R. Van De Water.

The New York County Medical Society.—Dr. George B. Fowler, president of the County Medical Society, announced at the stated meeting of that organization, on April 22d, that the committee of seven appointed to investigate the influence of prostitution on the public health was not yet ready to present its report. Those who read papers at the meeting were Dr. A. Ernest Gallant, Dr. Thomas S. Southworth and Dr. John H. Branth. The members of the society have been invited to take part in the proceedings of the American Congress on Tuberculosis, to be held in the Grand Central Palace on May 15th and 16th.

The National Association for the Study of Epilepsy and the Care and Treatment of Epileptics will meet in Washington, D. C., May 14th and 15th next. Many papers of value from European and American students, and full reports of the progress that is being made in the care and treatment of epileptics in this country, are promised for this meeting. The president of the association is Hon. William P. Letchworth, LL. D., Portage, N. Y.; first vice-president, Dr. Frederick Peterson, New York City; secretary, Dr. William P. Spratling, Craig Colony, Sonyea, N. Y. The officers will, upon request, furnish further information of the coming meeting.

The Cuyahoga (O.) Medical Society.—The annual meeting of the Cuyahoga County Medical Society was held on April 4th at Cleveland, O. The annual election of officers resulted in the choice of Dr. C. A. Hamann as president, Dr. C. C. Stuart and Dr. L. S. Chadwick vice-presidents, Dr. Frederick C. Herrick secretary, and Dr. C. G. Foote treasurer. Dr. C. J. Aldrich, the retiring president of the society, presented his address, which was a valuable paper on the diagnosis of meningitis or inflammation of the brain. A number of interesting cases were presented, one of them being a case of spina bifida, presented by Dr. L. B. Tuckerman; another a case of tabes arthropathy, presented by Dr. W. G. Stern.

The Convention of the Ohio State Medical Society.—Preparations are already being made at Cincinnati for the convention of the Ohio State Medical Society, which meets in May. The entertainment committee has made arrangements for the 500 or 600 medical men who are expected to attend. The following compose the committee: Dr. Louis Schwab, Dr. Giles Mitchell, Dr. John L. Cleveland, Dr. Ken Dunham, and Dr. W. D. Haines. The convention will be held in the Scottish Rite Cathedral May 9th to 12th. One of the most important matters taken up will be a general sanitary measure to be presented to the convention by Dr. Byron Stanton, a member of the State board of health.

The American Medical Association Meeting.—From the large number of persons who have already signified their intention of going to St. Paul to attend the meeting of the American Medical Association, June 4th to 7th, there is every reason to believe that arrangements can be made for a special train from New York. Those who desire to avail themselves of this opportunity should at once hand in their names to, or seek further particulars from, the secretary of the New York State Medical

Association, Dr. Frederick Holme Wiggin, 55 West Thirty-sixth Street, New York. The local committee of arrangements at St. Paul has announced that arrangements have been completed to run a special train through to the Yellowstone Park after the adjournment of the meeting. Full particulars regarding this excursion may be obtained from the chairman of the committee, Dr. John F. Fulton, St. Paul.

The Society for the Prevention of Consumption.—At a complimentary dinner tendered to Dr. Wm. G. Bissell, city bacteriologist in Buffalo, N. Y., on April 10th, there was organized the Society for the Prevention of Consumption. Only suggestions of its methods of work were made at the dinner, but it was decided that its principal function was to be the spreading broadcast of information concerning the disease. Dr. Benjamin G. Long, who first made the suggestion, was made chairman of a committee appointed to effect an organization. Associated with him on the committee are Dr. Bissell, Dr. Briggs, Dr. Gumaer, Dr. Thompson, Dr. Smith and Dr. Scott. Dr. Bissell was made secretary of the committee. The mayor of Buffalo will be asked to join the committee and assist in the work.

The American Academy of Medicine.—The twenty-sixth annual meeting will be held at the Hotel Aberdeen, St. Paul, Minn., on Saturday, June 1, 1901, at 11 A. M., the open session beginning at 12 M. and continuing through Monday, June 3d. The principal features of the meeting will be a symposium on Institutionalism, and another on Reciprocity in Medical Licensure. Series of valuable papers on both topics have been promised, as well as interesting papers on some other subjects. The President's Address, by Dr. S. D. Risley, of Philadelphia, will be delivered on Saturday evening, June 1st, and the annual social session held on Monday evening, June 3d. Members of the profession are always welcomed to the open sessions of the Academy. The secretary, Dr. Charles McIntire, Easton, Pa., will, on request, be pleased to send the programme, when issued, and blank applications for fellowship, etc.

Association of American Medical Colleges.—The next regular meeting of this association will be held at the Hotel Ryan, St. Paul, Minn., Monday, June 3, 1901. It will consist of two sessions, an educational session and a business session. The educational session will be opened at 2 P. M. by the president's address, followed by several papers of medical pedagogic interest. To this session all persons interested in medical education are respectfully invited. The representatives and associates of the Association of Southern Medical Colleges have received a special invitation. The members of the Confederation of State Examining and Licensing Boards are also invited. There will also be an exhibition of work done in medical colleges. At 8 P. M. the business session will be held, at which the amendments to the constitution proposed by several colleges will be considered. The report of the judicial council, the election of members and the election of officers for the succeeding year will close the programme.

The Tri-State Medical Society, composed of members of the profession from Iowa, Illinois and Missouri, closed one of the most important conventions of its history at Keokuk recently. The principal feature of the convention was the inauguration of a movement for the

enactment of strict marriage laws, and also to prevent the marriage of habitual criminals. This action was advocated in the address of the retiring president, Dr. Henry Hatch, of Quincy, Ill., and was endorsed by the convention. A committee, composed of Dr. J. C. Murphy, of St. Louis; Dr. D. C. Brockman, of Ottumwa, and Dr. Frank P. Norbury, of Galesburg, was appointed to present this matter at the next session of the legislatures of their respective States. The next convention will be held in Chicago. The following are the newly elected officers: President, Dr. J. C. Murphy, of St. Louis; first vice-president, Dr. Bayard Holmes, of Chicago; second vice-president, Dr. Ellet Orin Sisson, of Keokuk; treasurer, Dr. J. F. Percy, of Galesburg; secretary, Dr. W. B. Laforce, of Ottumwa; committee on credentials, Dr. Henry Hatch, of Quincy, Ill.; Dr. T. H. Throckmorton, of Charleston, Ia., and Dr. John Preston, of Kansas City.

The Medical Association of the District of Columbia.

—At the recent election of the Medical Association of the District of Columbia the following officers were chosen: President, Dr. H. L. E. Johnson; vice-presidents, Dr. G. C. Ober and Dr. William H. Fox; secretary, Dr. Monti Griffith; treasurer, Dr. Frank Leech. A standing committee was also elected, comprising Dr. McLean, Dr. Mayfield, Dr. Marbury, Dr. Acker, Dr. D. O. Leech, Dr. McLaughlin, Dr. Holden, and Dr. J. T. Howard. Dr. J. T. Thomas, Dr. E. L. Morgan, and Dr. Shands were appointed to serve on the board of censors. The following were named as delegates to the meeting of the American Association: Dr. H. L. E. Johnson, Dr. S. S. Adams, Dr. Glazebrook, Dr. Acker, Dr. Ober, Dr. G. L. Magruder, Dr. Cober, Dr. Griffith, Dr. Capehart, Dr. Chapell, Dr. W. C. Woodward, Dr. Yarrow, Dr. D. O. Leech, Dr. Jenner, Dr. Cooke, Dr. Shands, Dr. W. N. Fisher, Dr. Heiberger, Dr. McLean, Dr. Howard, Dr. W. H. Fox, Dr. Marbury, Dr. Wellington, Dr. Morgan, Dr. Prentice, Dr. Wallace, Dr. Johnson, Dr. Wall, Dr. Miller, Dr. Key, Dr. Robinson, Dr. Thomas, Dr. E. L. Morgan, Dr. T. C. Smith, Dr. Hicklin, Dr. Hall, Dr. Wall, Dr. Brown, and others. Dr. G. Wythe Cooke was designated to confer with the American Medical Association on State organization. Dr. H. L. E. Johnson was appointed to represent the District Medical Association at the annual conference of the committee on national legislation of the American Medical Association.

Foreign Obituary Notes.—Dr. Josef Fodor, professor of hygiene at the University of Budapest, is dead at the age of fifty-eight. He was a Knight of the Order of the Iron Crown.—Dr. George Dobbert, director of the Evangelical Sanatorium for Diseases of the Lungs at Pitkajärvi, Finland, died on March 5th at the age of sixty-four.—Dr. Julian Weinberg, the oldest physician of Warsaw, Poland, is dead at the age of eighty-six.

Foreign News Notes.—No passports will be issued to lepers by either Germany, Russia, or Roumania, an agreement to that effect having been entered into by the countries named.—Dr. Otto Ahnelt has been appointed city physician of Carlsbad.—A pharmacist of Budapest who dispensed "pastillæ corrosivi" when "pastillæ ascaræ" were ordered, causing the death of the patient, as sentenced to one year's imprisonment, the forfeiture of his license to practice pharmacy, and was fined 28,000 crowns. The court of appeals reduced the term of imprisonment by two months and remitted that part of the sentence forfeiting the license, on the ground that the

error was due to carelessness, and not to ignorance. The physician was not punished.

Foreign University News.—Dr. August Wasserman, a member of the Institute for Infectious Diseases, has become a *privat-docent* at the University of Berlin.—Professor Garré, a member of the privy medical council, has accepted a call to occupy the chair at Rostock vacated by Professor von Eiselsberg, who has gone to Vienna.—Dr. Shieck, formerly *privat-docent* in ophthalmology at Halle, has accepted a similar position at Göttingen.—An appropriation of 200,000 roubles has been made by the minister of war for the erection of new buildings for the departments of physiology, pathology, histology, and pharmacology at the Military Medical Academy at St. Petersburg.—Dr. Marwedd, *privat-docent* in surgery, and Dr. Nissl, *privat-docent* in psychiatry, at Heidelberg, have been made extraordinary professors.—Dr. J. Fibiger has been made professor of pathological anatomy at Copenhagen.

News of European Medical Societies.—The FIFTH INTERNATIONAL PHYSIOLOGICAL CONGRESS will be held from the 17th to the 23d of September at Turin, Italy, under the presidency of Professor Angelo Mosso. Those only are eligible for membership in the congress who belong to or are recommended for membership by some one of the national physiological associations.—The SECOND INTERNATIONAL CONGRESS OF INSURANCE SURGEONS will be convened at Amsterdam on September 23d. The general secretary of the congress is Dr. Poel, 2 Rue Marie, Brussels, to whose energetic initiative the holding of the congress is due.—The Association of German Naturalists and Physicians will hold its seventy-third annual meeting at Hamburg from the 22d to the 28th of September. An unusually interesting programme is promised. Dr. Abel has been selected to act as secretary of the general committee.—The French Surgical Congress will take place at Paris from October 21st to 26th.—The fourth Italian Congress of Pædiatrics will be held at Florence from the 15th to the 20th of October, and the following themes have been already announced: Primary Infantile Atrophy, by Dr. Fede and Dr. Berti; Sepsis of the Respiratory Organs in Early Childhood, by Dr. Mya and Dr. Mensi; and Acute Infection of the Digestive Organs, by Dr. Concetti and Dr. Guaita.

Small-pox.—The number of sufferers from this disease in and around New York city hardly seems on the decrease. Many cases are reported from Jersey City, Bloomfield, N. J.; several places in Tennessee, Beloit and other cities in Wisconsin and Michigan; Sharon and other points in Pennsylvania, and at Topeka, Kans., where cases have developed in the Topeka Insane Asylum, which contains over 1,000 inmates. Many of the employés of the institution are resigning.

"The Sleeping Sickness" and Malaria; a Portuguese Medical Expedition.—According to the *British Medical Journal* for April 6th, a commission has been appointed by the Portuguese government to study the sleeping sickness in the province of Angola. This commission, which will at the same time include among its scientific researches an inquiry into the ætiology and the transmission of malaria, will be composed of the following members: Dr. Annibal Bettencourt, Dr. Ayres José Kopke Correa Pinto, Dr. José Gomes Rezande, Jr., Dr. Joao Braz Gouveia, and Dr. Annibal Celestino Correa Mendes.

Typhoid.—According to the newspaper reports, the typhoid fever epidemic at New Haven, Conn., reached alarming proportions during the past week. A total of 300 cases were reported, and it was believed the list would reach 1,000 before the epidemic is checked. At least a part of the city water supply is believed to be contaminated, and the water from Lake Dawson, in Bethany, has been shut out from the city pipes. Requests for trained nurses were sent to all parts of New England and to New York, but not enough nurses to begin to fill the demand can be obtained. Nearly all the doctors in Connecticut have been pressed into service.

A Committee of the Medical Board of the City Hospital Objects to Charter Provision.—Edward S. Peck, C. L. Gibson, Charles C. Ransom, Robert H. M. Dabarn, Alfred N. Strouse and Nathaniel Bowditch Potter, members of a committee appointed by the Medical Board of the City Hospital to take action in regard to the amended city charter so far as it affects Bellevue and its allied hospitals, have presented their report. The committee objects to the proposed changes, giving its reasons for doing so.

Hospital Buildings and Endowments.—The bill of Senator Hennessy appropriating from the treasury of New York city \$300,000 for a hospital in the borough of the Bronx has been passed at Albany.—A bill has passed the New York Assembly providing for an appropriation of \$100,000 for the quarantine stations at Hoffman and Swinburne islands.—The bill of Mr. Kelsey appropriating \$188,000 for the Craig Colony of Epileptics has passed the Assembly of New York State.—Commissioner Sexton, of the Department of Health of this city has been authorized to expend without public letting \$10,000 for a small-pox pavilion in connection with the Riverside Hospital on North Brother Island.—The Health Department of New York city has decided to establish an emergency hospital and ambulance service at Coney Island, which has been without any attention in that direction since 1898. The emergency hospital will be fitted up in the old building formerly used as a police station.—At a meeting of the Academy of Medicine, Dr. W. A. Holden, one of the assistant physicians of the department for diseases of the eye at the Vanderbilt Clinic, spoke in favor of the establishment of a hospital for the treatment of contagious diseases of the eye.—J. Pierpont Morgan has purchased and presented to the Loomis Sanitarium for Consumptives at Liberty, N. Y., the entire plant of the Liberty Electric Light and Power Company. The cost is said to have been \$40,000. Dr. J. E. Stubbert, the physician in charge of the sanitarium, and professor of pulmonary diseases at the New York Post-graduate Medical School, was elected president of the new company, and has taken charge of the plant.—The Lackawanna (Pa.) Hospital Corporation has offered to give to the State of Pennsylvania its property for a miners' hospital. It is worth \$200,000, and is free from all debt. It is argued that as the State has already provided at its own expense two miners' hospitals in the anthracite region, one at Ashland, in Schuylkill county, and one at Hazleton, in Luzerne county, it ought to have one in the northern districts. A bill to make the Lackawanna Hospital a State institution is now before the legislature.—The Maryland Medical College, of Baltimore, Md., has bought two three-story dwellings at Calhoun and Fayette streets, which it will convert into an up-to-date hospital, to be

conducted in connection with the college. The purchase price is said to have been in the neighborhood of \$14,000. About \$5,000 will be spent in improvements, and the erection of an annex is also contemplated.—The Georgia Eclectic Medical Association, in session in Atlanta recently, decided on the erection of a \$15,000 eclectic hospital, to be located on their grounds. Work is to be begun at once.—The St. Joseph's Hospital Association of Denver, Col., has bought two lots adjoining the hospital, on which an extension to the present building is to be erected.—The Virginia Coal and Coke Company is preparing to build a large hospital at Stonega, Ky., similar to the large State institutions built in the mining regions of the north. Work will begin on the hospital May 1st.—A new contagious diseases hospital will be built at Ottawa, Ill., to cost about \$40,000.—A group of new contagious hospitals is to be erected at Brookline, Mass., at a cost of \$86,500.—Designs for new hospital buildings for the German General Benevolent Society of San Francisco have been invited from architects. The limit of time is August 1st. Over \$250,000 will be expended on the buildings, and prize will be awarded for the four designs which shall be considered best—first, \$2,000; second, \$1,000; third, \$750 and fourth, \$500.

Births, Marriages, and Deaths.

Married.

BRITTIN—PAINTER.—In Auburn, Illinois, on Tuesday, April 9th, Dr. William A. Brittin and Miss Anna Huntington Painter.

BYRD—BARRON.—In East St. Louis, Missouri, on Wednesday, April 10th, Dr. Ritchie L. Byrd, of De Soto, Missouri, and Miss Gertrude Barron.

CANTON—WILKINSON.—In Washington, on Wednesday, April 10th, Dr. George E. Canton, of Jersey City, and Miss Elizabeth G. Wilkinson.

COLE—COOPER.—In Albany, on Wednesday, April 17th, Dr. Charles Gray Cole, of Binghamton, N. Y., and Miss Ann J. Cooper.

EMERY—HAYES.—In Middletown, N. Y., on Wednesday, April 17th, Dr. William Gordon Emery and Miss Jenn Madeline Hayes.

GUEST—BLANCHAUD.—In Montreal, Canada, on Wednesday, April 17th, Dr. Middleton Sims Guest, of Philadelphia, and Miss Marie Ida S. Blanchaud.

O'GORMAN—MCQUAID.—In Brooklyn, on Monday, April 15th, Dr. M. William O'Gorman and Miss Sarah Julia McQuaid.

REATH—PANCOAST.—In Philadelphia, on Thursday, April 18th, Dr. Benjamin B. Reath and Miss Florence Pancoast.

ROSENTHAL—MILLER.—In Cincinnati, on Wednesday, April 10th, Dr. C. H. Rosenthal and Miss Ida Miller.

TASCHEREAU—O'RYAN.—In Bedford Park, N. Y., on Thursday, April 18th, Dr. Gustave A. Taschereau, of St. Ferdinand, Nova Scotia, and Miss May Matilda O'Ryan.

WIESE—KOENIG.—In St. Louis, on Wednesday, April 17th, Dr. William Wiese and Miss Bertha Koenig.

Died.

ADAMS.—In Portland, Maine, on Sunday, April 14th, I. Cephas G. Adams, in the seventieth year of his age.

BROCKWAY.—In Brattleborough, Vermont, on Sunday, April 21st, Dr. Frederick J. Brockway, of New York, in the fortieth year of his age.

DANA.—In Tunkhannock, Pennsylvania, on Wednesday, April 17th, Dr. Charles W. Dana, in the forty-fifth year of his age.

GRAHAM.—In Pittsburgh, on Sunday, April 14th, I. Thomas Phillips Graham, in the sixty-first year of his age.

HERMANSE.—In Brooklyn, on Tuesday, April 16th, I. Alerio Hermanse, in the sixty-seventh year of his age.

MCCLELLAND.—In Denver, on Friday, April 12th, Dr. William F. McClelland, in the eightieth year of his age.

Pith of Current Literature.

Medical News, April 20, 1901.

A Historical Sketch of the Department of Medicine and Surgery of the University of Michigan. Special Article.

Some Errors in the Examination of Urine. By Dr. Louis Heitzmann.—Although the presence of albumin is undoubtedly of some significance in every case, it does not necessarily follow that a lesion of the kidney must exist at the same time, since the presence of pus corpuscles, no matter from what cause, is sufficient to give a positive reaction. The author points out, therefore, that no diagnosis of nephritis should be made without the aid of the microscope. He believes that the most reliable test for albumin is heat and acetic acid. As to the statement that, although true casts are most commonly found in pathological lesions of the kidney, they may be seen in individuals in whom the kidneys are perfectly normal, the author asserts that, if this is correct, we do not as yet know what casts really are. He believes, however, that the difficulty lies in not distinguishing between true and false casts. Hyaline, epithelial, blood, granular, fatty, and waxy casts, are the only true casts, the first three being found in acute, the others in subacute and chronic inflammations. The author comments upon those reports of urine examinations which state that no albumin is present, that pus corpuscles, red blood corpuscles, and epithelia are absent, but that hyaline and granular casts are found in varying numbers, and in which, therefore, a diagnosis of parenchymatous nephritis is given. He shows that, from the very nature of true casts, it is perfectly plain that they can never be found in urine without some other evidences of inflammation, such as pus corpuscles, red blood corpuscles, and epithelia. In regard to the use of the centrifuge, he believes that since it presents no advantage over the old method of allowing the urine to stand for six or twelve hours, it should not be used, with the sole exception of examining for tubercle bacilli, which latter are more easily found in centrifugated urine. He points out, finally, that as casts are almost invariably absent in interstitial nephritis, the diagnosis should not necessarily depend on their presence, and he asserts that pus corpuscles, red blood corpuscles, and kidney epithelia are sufficient for a diagnosis.

Acute Traumatic Malignancy. By Dr. William B. Coley.—A series of illustrative cases, concluding an article commenced in the preceding issue.

Epistaxis. By Dr. Charles N. Cox.—Unless bleeding has actually ceased when the patient is seen, the bleeding nostril should be cleansed, when, in a large proportion of cases, the source of the bleeding can be seen, and it only remains to put some sort of a tampon over the leak in such a manner as to be retained in place and to make firm pressure. For the more severe forms of bleeding, local styptics are of no avail, and should not be relied on when we have at our command the more rational means of mechanical pressure. Should it become necessary to resort to guesswork and plug the whole nostril, the author prefers to use long strips of sterile or iodoform gauze, about one half or three quarters of an inch in width. It will seldom be found necessary to introduce posterior plugs, and they should be avoided, if possible. The author protests against the use of Monsell's solution of the subsulphate of iron as a styptic, on account of the hard plaster-like coagula it forms. An application to

the bleeding point of the solid stick or of a fifty-per-cent. solution of silver nitrate, may be used as an adjuvant to mechanical pressure, or alone if it controls the hæmorrhage. As a spray to the bleeding surface he recommends:

℞ Extract of suprarenal capsule... 20 grains;
Glycerin..... 1 drachm;
Water..... 3 drachms.

M. Macerate for half an hour, filter and then boil the solution for a few minutes to sterilize it.

Medical Record, April 20, 1901.

The Toxæmia of Pregnancy; its Diagnosis and Treatment. By Dr. S. Marx.—The author's belief is that the toxæmia of pregnancy is a complex condition depending on more than one factor. Many women go to term with albuminuria, without symptoms referable to toxæmia. When such symptoms arise, they are not caused by the albumin present, but by faulty excretion of urea. In the most desperate and malignant cases there is found neither albumin nor casts. Urea is always found to be markedly diminished in the so-called true toxæmias. The author makes a strong plea for a regular and methodical course of urea-estimation in all cases of toxæmias of pregnancy, or urinæmias. He also makes a strong plea for a regular and methodical course of urea-estimation in all cases of toxæmia. He believes that progressive diminution of urea excretion, with or without albuminuria, is the sole indication for the induction of premature labor, which is especially indicated when conscientious medical treatment fails.

Faith Cures and the Law. By Dr. John B. Huber.

Report of Three Cases of Malignant Endocarditis, One Following Measles, another Typhoid Fever in a Child and Simulating Splenic Lymphatic Leucæmia, and another Terminating in Recovery. By Dr. Albert E. Roussel.—In regard to the relation existing between simple and malignant endocarditis, the author accepts the modern view that the difference between the two forms depends upon the virulence of the micro-organisms or their toxins. The micro-organisms are almost always found in the vegetations on the valves in the infectious form, but are also frequently found in the so-called simple variety, and the same micro-organisms are found in both. When they act as irritants, inflammation results, and the case is one of simple endocarditis; but inflammation plus necrosis is septic endocarditis.

Strangulated Hernia in Infants; Description of a hitherto Unrecognized Cause and Seat of Strangulation. By Dr. Alexis V. Moschowitz.—The two cases are interesting, not only on account of the age of the infants (three and four months respectively), but also on account of the hitherto unrecognized location of the constriction, low down in the scrotum at a considerable distance from the external inguinal ring.

Journal of the American Medical Association, April 20, 1901.

Jules Lemaire, the First to Recognize the True Nature of Wound Infection and Inflammation and the First to Use Carbolic Acid in Medicine and Surgery. By Dr. Howard A. Kelly.

Tracheloplasty. By Dr. Henry Parker Newman.

The Physiologic Care of Colds. By Dr. Charles H. Shepard.—The author states that the condition called a cold is one of repletion, and often results from imperfect elimination, or an inactive condition of the excretory

organs. There can be no more prolific cause of colds than highly seasoned foods, as well as frequent eating. To make a radical cure of a cold, the author advises the patient to abstain entirely from food for at least twenty-four hours. If the bowels are at all inactive, it is desirable that they should be thoroughly flushed with warm water. The patient should drink freely of water and take a brisk walk in the open air, and then a Turkish bath. Chronic cases need more persevering treatment, but each day will show progress, and only perseverance is needed to triumph ultimately over the morbid action. The practice of administering quinine to break up a cold is condemned by the author, because it debilitates the nervous system and weakens the condition of the heart. A simple "cold in the head" may be successfully treated by drawing hot water into the nostrils and then blowing it out, repeating the process several times until the nose is thoroughly cleansed. For those in fair health the author recommends the practice of cold bathing in the morning, particularly if a warm shower precedes the cold, or a short stay in a warm room precedes the cold plunge.

Atrophy of the Mucous Membrane of the Stomach. By Dr. Freeman F. Ward.—The author reports five cases of this affection. He emphasizes the point that the impression that the absence of free hydrochloric acid is a sign of malignant disease, is an erroneous one. In the cases cited, absence of free hydrochloric acid was marked, and, despite this fact, there were no symptoms whatever of malignant disease. His experience corresponds with that of Einhorn, that, as a general rule, in cases of atrophy of the mucous membrane of the stomach, there exists a condition of chronic diarrhoea. He lays stress upon the importance of making careful examinations and analyses of all the secretions, including the gastric juice of patients suffering from chronic disturbances of the stomach and bowels.

Some Notes on Two Cases of Voluntary Laryngeal Whistling. By Dr. G. Hudson Makuen.—In one of these cases the aryepiglottic folds were used as the lips of the mouth are used in whistling, and, so far as the author could determine, no other parts of the larynx were employed. In another case, quoted by the author, the ventricular bands were approximated and puckered up, leaving an elliptical opening in the centre through which the vocal cords could be seen with their thin edges vibrating, thus producing the whistling.

Some Anomalies of the Ear Due to Errors in Development. By Dr. George C. Stout.—The author finds that, as a rule, supernumerary auricles are pre-auricular, usually unilateral, and can be removed without unpleasant sequelæ.

Care and Use of Instruments. By Dr. Allen De Vilbiss.—The author believes that the surgeon should attend to his own instruments, and he asserts that the idea is absurd that a person can possess the skill necessary to remove a spur from the *sæptum nasi* in a workmanlike manner, and not be able to acquire the proper use of his hand to prepare his instruments for their work. He asserts that no person should be allowed to practise surgery without having first learned a mechanical trade.

Surgical Diagnosis of Abdominal Tumors. By Dr. W. H. Earles.

A Contribution to the Study of Mountain Fever. By Dr. R. Harvey Reed.—Some of the particulars in which there is a marked difference between typhoid and mountain fever are: (1) In the reaction with Widal's

test, a large majority of cases show a positive reaction in typhoid fever, while the reverse is the case in mountain fever; (2) the mortality of typhoid is much greater; (3) the average duration of the disease is greater in typhoid fever; (4) the cause of mountain fever does not seem to lie in the presence of the Eberth and Gaffky bacillus; (5) the rise and fall of temperature in mountain fever is more abrupt than that of typhoid fever; (6) tympanites is nearly always present in typhoid and seldom present in mountain fever; (7) epistaxis is common in typhoid, but rare in mountain fever; (8) intestinal hæmorrhage is also common in typhoid and rare in mountain fever; (9) the eruption in typhoid fever is usually confined to the abdomen, is not raised, and disappears readily on pressure, returning promptly when the pressure is relieved, while the eruption in mountain fever covers almost the entire body, is raised, has a shotty feel under the finger, and does not disappear on pressure.

A Study in the Hæmatology of Neurasthenia. By Dr. Charles Howard Lodor.

Intubation of the Larynx, with Personal Reminiscences. By Dr. F. E. Waxham.

Some Points in the Diagnosis of Gall-stones. By Dr. James B. Herrick.

The Present Status of Spinal Surgery. By Dr. Samuel Lloyd.

Philadelphia Medical Journal, April 20, 1901.

The Localization of Brain Tumors, Especially with Reference to the Parietal and Prefrontal Regions. By Dr. Charles K. Mills.—The author reports an interesting series of cases which demonstrate that the diagnosis of the existence of a brain tumor can sometimes be made, even in the absence of most of the general symptoms, such as optic neuritis, headache, vertigo, and vomiting, chiefly by the close study of localizing and invasion symptoms. Emotional states, even hysterical stigmata, are sometimes present in cases of brain tumor, and must not be given too much weight in diagnosis. Tumors of the posteroparietal region, and especially of the superior parietal lobule, give, as their most important localizing symptoms, disorders of cutaneous and muscular sensibility, and especially astereognosis; other symptoms often present in such cases are the result of compression or invasion of adjoining regions. Tumors and other lesions implicating the angular gyrus and the regions adjoining, give, as their main localizing symptoms, word-deafness and word-blindness, with the usually accompanying speech-disturbances, lateral homonymous hemianopsias and disorders of cutaneous and muscular sensibility, including astereognosis. Tumors of the prefrontal region chiefly give psychical symptoms of a special character; when the tumor is situated on the left side, motor agraphia and motor aphasia are usually present, because of the compression or invasion of the second frontal and of the third frontal convolutions; paralysis and other motor symptoms are often present late, because of encroachments upon the motor region.

Non-surgical Treatment of Fibroid Tumors of the Uterus. By Dr. Augustin H. Goelet.—The author places electricity foremost among non-surgical measures for fibroid tumors of the uterus. Both the galvanic and the faradaic currents, and even static electricity, may be employed with benefit. Upon the electrolytic action of the galvanic current the author relies mainly to reduce the size of the growth and to cause its dissipation. When it fails to accomplish this result, it is a material aid in

relieving the symptoms, particularly the pain produced by pressure and congestion. It also stimulates the absorption of exudates, and removes many of the adhesions, this latter result being accomplished by shrinkage of the mass, from contact with adjacent structures to which it has become adherent, and consequent stretching and giving way of the adhesions. He has found ergot, administered internally, to be a valuable auxiliary in some instances, and the iodide and bromide of potassium to be useful sedatives.

Acromegaly, with Report of Two Cases. By Dr. W. G. Shalleross.

A Clinical Note on Infantile Scorbutus. By Dr. Wm. M. Mastin.—The author refers to the impression that seems to prevail among the members of the profession, that scurvy in the first years of child life is a very rare affection, and, on the other hand, that rheumatism in infancy is quite common. He points out that the reverse is true, and the cases adduced demonstrate that errors in the diagnosis of infantile scurvy are not confined alone to rheumatic affections, but may extend to the domain of surgical disorders—tuberculous bone lesions, sprains, and contusions; to the nervous system—disease of the cord; and that they even include hereditary syphilis.

Susceptibility to Disease and Physical Development in College Women. By Arthur MacDonald.—A statistical article of moderate interest.

Operative Treatment for Prostatic Hypertrophy. By Dr. Ramon Guitéras.—The author looks forward to prostatectomy as the operation for the radical treatment of prostatic hypertrophy in the future. In a general way, he says that very old men with prostates not very large, but causing considerable urethral impediment, are cases for Bottini's operation, while younger men with large prostates as felt through the rectum, with good kidneys and bladder, are fit subjects for enucleation.

Boston Medical and Surgical Journal, April 18, 1901.

The Opinion Evidence of Medical Experts. By John D. McLaughlin.—The author briefly sketches some features of foreign law in its attitude toward the testimony of medical experts, and, while he would not be understood as advocating the modelling of our own law according to the same plan, he points out that the real keynote and underlying principle of Continental countries, in this respect, is that the expert should be the partisan of neither side; that he should be as dispassionate and just as the judge; and that, in fact as well as in theory, he should be the assistant of the court. This principle, if we are to hope that at some future time the medical expert shall enjoy all the respect and credence that is his right and the right of science, must be followed in some form or other. And if we are to reform our procedure in this regard, relief must be sought finally, asserts the author, in the body of the Roman jurisprudence.

The Umillian Murder. By Dr. Herbert B. Perry.

Leucocytosis and Typhoidal Perforation. From the **Medical Clinics of the Montreal General and Royal Victoria Hospitals.** By Colin K. Russell, B. A.—The cases cited by the author lead to the following conclusions: (1) That in perforation it is the general rule to have a leucocytosis, but the degree may vary within wide limits; (2) that the leucocytes, while appearing, as a rule, early, may not be at all marked until general peritonitis and collapse have supervened; (3) that there may be an utter absence of leucocytosis with marked perforation and peri-

tonitis, in fact, that the cells may be lower than normal; (4) that with typical signs of perforation and a definite leucocytosis there may be no such complication present, and an operation may be performed unnecessarily; (5) that a marked degree of leucocytosis may occur in complications other than perforation—for example, bronchitis, cholecystitis, etc.; (6) that with pain and tenderness in the abdomen, coming on suddenly during an attack of typhoid fever (and in the absence of evidence of cholecystitis or other definite complication), and a distinct leucocytosis, even without other signs of perforation, an exploratory operation is justifiable, even advisable, thereby obviating the dangers of a fatal issue from too great a delay.

Upon what Sort of Information shall a Medical Examiner Hold a View? By Dr. H. M. Cullo.—The author gives a case in which the question indicated in the title arose, and after a brief review of the literature and reference to precedents, concludes, in the words of Dr. Amory, that it is better "to err in cases of doubt upon the side of too much rather than too little investigation," and that the exact procedure in all cases cannot be laid down.

Contusion of the Abdomen; No External Wound; Rupture of the Descending Colon; Fæcal Abscess; Drainage; Suture of Ruptured Gut; Recovery. By Dr. Charles L. Scudder.—The particular interest in this case lies in the fact that the rupture of the bowel was not attended by such symptoms as would ordinarily lead one to suppose that a serious injury had been received. The very important sign that was misinterpreted was that of vomiting. This symptom, instead of being explained by the patient's statement that he had eaten something indigestible before he was injured, should have suggested a lesion of the bowel, or at least serious involvement of the peritonæum. The author points out that a single vomiting of the stomach-contents after an abdominal contusion is of no special importance. Continuous, unexpected vomiting without any apparent reason is significant of an intestinal lesion. This is true despite the absence of other signs of peritoneal involvement.

Lancet, April 13, 1901.

The Topographical Anatomy of the Abdominal Viscera in Man. By Dr. C. Addison.—The third and last of the Hunterian lectures upon this subject. Among the points of interest brought out in this article are the following: A small recurrent branch of the appendicular artery is often found in the ileocæcal fold of the peritonæum, so that the term "bloodless fold," as used by Treves, is incorrect. The internal or proper retrocolic pouch was well defined in eight cases (20 per cent). It often contains the root of the appendix. The sigmoid flexure of the colon over the left psoas muscle has a very short mesentery. The commonest variation of the mesosigmoid is the obliteration of its outer limb. In the forty cases these conditions occurred with the following frequency: 1. Presence of both limbs, 27 cases, or 67 per cent. 2. Complete absence of the outer limb, 11 cases, or 27.5 per cent. 3. Abnormal cases in the presence of a descending mesocolon, 2 cases. The positions of the vermiform appendix fall into four groups: 1. Wholly within the pelvic cavity, 6 cases, or 15 per cent. 2. Free, hanging more or less over the pelvic brim, 16 cases, or 40 per cent. 3. Wholly in the iliac fossa, 14 cases, or 35 per cent. 4. Irregular cases, 4, or 10 per cent. (In 8 cases, or 20 per cent., the appendix was either recurved into a retrocolic pouch or was firmly fixed behind the

peritonæum.) The lowest point of the cæcum is situated, as a rule, in the right lateral line about half an inch below the level of the anterior superior iliac spine. There are two chief varieties in the shape of the transverse colon: 1. The loop represents a permanence or exaggeration of the primitive bend of the colon at this place. 2. Complete absence of the downward hepatic loop, the transverse colon passing directly across the abdomen. For practical purposes a point in the left lateral line at the level of the anterior superior spine may be taken to correspond to some part of the lumen of the sigmoid flexure at the place where it somewhat abruptly becomes freely movable. The right kidney, apparently in the absence of laxity of its enveloping connective tissue, is very much independent of pressure from the liver above or from the stomach below. A high position of the spleen seems to be associated with a highly placed stomach, but the reverse does not hold. There is no relationship between the level of the spleen and the left kidney. In 29 cases (72.5 per cent.) the upper pole of the right kidney was lower than that of the left kidney; in 3 cases it was at the same level, and in 8 cases (20 per cent.) it was higher.

On the Importance of Early Diagnosis and Treatment in Surgical Diseases of the Abdomen. By W. Rose, M. B.

Postpartum Hæmorrhage. By E. S. Bishop, F.R.C.S.—In this article the author sketches very lucidly and thrillingly the course of a supposititious case of postpartum hæmorrhage, from its beginning to its fatal termination, describing the various measures taken by the attendant physician. All authorities agree that two definite ends are aimed at: Contraction of the uterus, and local coagulation of the blood. After reviewing briefly the various procedures, mechanical and therapeutical, advised in text-books, the author strongly urges the following in every case: 1. Elevation of the foot of the bed, and further elevation of the legs, in this way controlling the venous loss of blood. 2. Compression of the abdominal aorta, thus shutting off five sixths of the uterine blood supply. The closed fist is applied with its ulnar surface resting upon the aorta as it lies over the left side of the vertebral column, and just sufficient pressure is exerted obliquely backward and toward the right so as to enable it to compress that vessel against the unyielding surface beneath. The aortic pulsation soon becomes strong and vigorous, the bleeding stops, and the uterus can be cleared out, and any lacerations in the genital cavæ reunited. 3. Traction on the cervix, which kinks and closes the uterine vessels. This last procedure is only to be made use of while clearing out the uterus, repairing tears, etc.

The pressure on the abdominal aorta is the important point, and is to be continued until the blood pressure has become full and strong and the uterus has contracted, *i. e.*, recovered its muscular force. On removing the hand, should the hæmorrhage begin again, it can be again checked in the same way. The foot of the bed should be kept elevated for twenty-four or forty-eight hours, so as to favor the concentration of the amount of blood remaining in the patient.

Remarks on Enlargement of the Inguinal Glands Chiefly in Connection with the Diagnosis of Primary Syphilis. By A. Cooper, M. R. C. S.—Although multiple indolent glands form one of the most important features of primary syphilis, it must be remembered that they are not in themselves proof of it, and that an apparently typical condition of the groins is sometimes due

to other causes, more especially in persons whose glands are unusually susceptible. Among such causes may be mentioned severe gonorrhœa, urethral irritation from too strong injections or other injury, irregular herpes, severe balanoposthitis, and tuberculosis. The diagnosis will depend on the history, on the absence of an indurated primary lesion, and on careful watching throughout the incubation period of syphilis. Too much is sometimes expected in the way of glandular enlargement as well as of induration of the primary lesion of syphilis. Different persons vary greatly as regards susceptibility to glandular enlargement. Tuberculous subjects seem to be most liable to have the lymphatic glands affected on slight provocation. A man who is apparently healthy and without any history of venereal or other disease to account for it, may, knowingly or not, have a degree of indolent enlargement of the inguinal glands, which of itself is indistinguishable clinically from that which is found in some cases of primary syphilis.

Remarks on the Holmgren Test. By Dr. F. W. Edridge-Green.—The author holds that the Holmgren wool test for color-blindness is inefficient, that a great number of normally sighted persons are rejected and three divisions of the dangerously color-blind nearly always escape detection by it. He cites numerous authorities who confirm him, and urges that a fresh inquiry be made into the subject. A lantern test could be constructed which would detect all cases.

The Chemistry of Nerve Degeneration. By Dr. F. W. Mott and Dr. W. D. Halliburton.—The authors have previously shown that in general paralysis of the insane the marked degeneration that occurs in the brain is accompanied by the passing of the products of degeneration into the cerebrospinal fluid. Of these nucleoproteid and choline are those which can be most readily detected. They now find that choline can also be detected in the blood in disseminated sclerosis, combined sclerosis, alcoholic neuritis and beri-beri. The tests employed are two: (1) A chemical test—namely, the obtaining of the characteristic octahedral crystals of the platinum double salt from the alcoholic extract of the blood; and (2) a physiological test—namely, the lowering of blood pressure produced by a saline solution of the residue of the alcoholic extract.

It is possible that such tests may be of diagnostic value in distinguishing between organic and so-called functional diseases of the nervous system.

British Medical Journal, April 13, 1901.

Some Cases Illustrating the Surgery of the Large Intestine. By C. A. Morton, F. R. C. S.—The author reports the following cases: 1. Ventrofixation of the sigmoid flexure for prolapse of the rectum in an adult. The fixation sutures were passed through the mesosigmoid, and not through the intestinal wall itself. The patient did very well, but of late there has been a slight return of the prolapse. 2. A case in which a malignant tumor of the cæcum simulated movable kidney; excision of the cæcum and glands in the mesentery; no recurrence two years after the operation. 3. A case of intestinal obstruction from malignant growth in the colon; colotomy and fixation of the tumor outside the peritonæum; subsequent removal of tumor. The patient died one year and nine months after the removal of the primary growth.

Cholecystectomy; Partial Hepatectomy and Pylorotomy; Recovery. By B. C. Stevens, M. B.—The author reports a case of cholelithiasis occurring in a woman

ged fifty-four years and associated with malignant disease involving the liver, gall-bladder, and pylorus, and complicated by an abscess in the abdominal wall. At the operation two large stones were removed from the gall-bladder, and then the gall-bladder, the margin of the pylorus, and the pylorus, all of which were carcinomatous, were removed. Two months after the operation the patient was progressing favorably and gaining strength. The case is of interest in several respects: 1. In the association of abscess and cancer, both being dependent on the irritation of gall-stones. 2. In the occurrence of a stulous tract between the gall-bladder and the stomach. 3. In showing how difficult it is sometimes to make an exact diagnosis before abdominal section. 4. In demonstrating how the surgeon must be prepared for any emergency in operating for gall-stones. When cancer attacks the gall-bladder it is usually secondary to gall-stones, and less frequently to extension of cancer from adjoining organs. When the gall-bladder becomes attached to any hollow viscus, a fistula may form, and fistulae in connection with the bile passages are in fact not uncommon.

A Case of Sarcoma of the Brain Removed by Operation; Subsequent Operation for Removal of a Second Tumor; Recovery. By Dr. J. M. Clarke and Dr. R. G. Lansdown.—The features of interest in this case were the presence of symptoms unmistakably pointing to an intracranial neoplasm, and with one exception being entirely "general" symptoms. The only positive indication or localization of the growth was an alteration in the percussion note over an area in the parieto-occipital region of the skull, and the recognition of this sign led to the trephine opening being made directly over the tumor. At the first operation a firm rounded growth, about an inch and three quarters in diameter and half an inch in thickness, and distinctly encapsuled, was easily shelled out. About six weeks later signs of a second tumor in the same region appeared, and another operation resulted in the removal of a very large tumor. This could not be removed as a whole, but was divided into two or three large pieces which weighed altogether six ounces and a quarter. No recurrence up to January 30, 1901, had taken place, the operation relieved the patient of his symptoms, the hemiplegia which resulted from the last operation cleared up, and the mental condition was nearly normal, but the sight, greatly impaired at the time of operation, improved very little. Microscopical examination showed the tumors to be typical sarcomata.

Case of Cavernous Angeioma of the Orbit. By A. Whitehead, M. B.—The author reports a case of this rare affection occurring in a man aged fifty-one years. The right eye was pushed forward by a rounded elastic tumor, the proptosis being so extreme that the lids could not be closed, and ulceration of the cornea had already taken place. At the operation the external canthus and external rectus were cut, thus exposing the tumor, which was removed *en masse*. Recovery was uneventful, and vision rapidly improved. Slowness of growth and absence of pain are among the most characteristic signs of the affection. The mobility of the eye is usually preserved. In this case is unusual in the size of the growth, the amount of fibrous tissue present, and the preservation of the eye, with practically no deformity and with restoration of almost normal vision.

The Saline Treatment of Dysentery. By W. J. Buchanan, M. B.—In the *British Medical Journal* for February 10, 1900, the author published a note on the results of treatment of dysentery by salines, based on 5 cases, with only 6 deaths. The present note deals

with the results of 300 more cases which have been treated with salines, with only 3 deaths, thus making a total of 855 cases with 9 deaths, or a mortality of about 1 per cent. The saline treatment is advocated for acute cases only; it is not safe for chronic or relapsing cases with ulceration of the colon. The following mixture was used:

R Sodii sulphatis. 1 drachm;
 Aquæ fœniculi, ad. 1 ounce.

This was given four, six, or eight times a day as required, and continued until every trace of blood and mucus had disappeared from the stools.

The Resistance of the Larval Mosquito to Cold. Notes on the Habits and Life-history of Mosquitoes in Aberdeenshire. By M. J. Wright, M. B.—There is no proof of the generally accepted view that the adult mosquito is able to survive the rigors of winter in a state of hibernation, and when warm weather comes turns active and lays eggs, thus providing for the perpetuation of the species. From the observations of the author on the extreme prolongation of the larval stage and the power of the larvæ to withstand low temperatures it seems reasonable to infer that it is really the larvæ that provide for the continuation of the species through winter in northern countries. It is during winter that one may hope to do most toward exterminating mosquitoes. In kerosene oil we have a most efficient larvicide, but it should be applied continuously, not intermittently. Suspend a vessel full of oil over the water, and arrange for its discharge a drop at a time.

A Case of Recurrent Alcoholic Peripheral Neuritis. By Dr. L. H. Jones.—The author reports the case of a woman who had severe alcoholic peripheral neuritis from taking whiskey in moderate quantity. She recovered almost completely, but eleven years later, being compelled to undertake domestic duties of the most arduous nature, she again had recourse to stimulants, taking three glasses of Burgundy a day. This was sufficient to cause a recurrence of the neuritis, with typical wrist-drop and all the other attendant symptoms. The author holds that alcohol is responsible for much that has occurred in the recent outbreak of peripheral neuritis in Manchester, and that in a great measure the arsenic has acted on systems saturated with alcohol much as a candle-end would on a smouldering fire.

A Case of Neuritis Affecting the Optic and Cervical Nerves, Complicated by Carcinoma of the Breast. By J. R. Benson, F. R. C. S.

Case of Foreign Body in the Bronchus; Tracheotomy; Recovery. By F. B. J. Baldwin.

A Note on Acute Dilatation of the Heart. By H. O. Nicholson, M. B.

A Note on the Treatment of Genu Valgum. By E. M. Little, F. R. C. S.

A Polypoid Excrescence of the Tonsil. By Dr. E. S. Yonge.

Indépendance médicale, April 3, 1901.

Recurrent Ulcer of the Stomach.—M. Hayem says that we know nothing of the causes of ulcer of the stomach. Under the influence of some alimentary vice, a hyperpeptic or glandular gastritis develops, with the production of free hydrochloric acid and increased fermentation. In a recurrence, the scars and former adhesions play an important rôle, providing a permanent focus of disturbance which accounts for the hæmorrhages. Under the influence of increased peristalsis at times, or some

traumatism, adhesions rupture, the gastric contents are poured into the peritoneal cavity, and peritonitis results. The ulcer may undergo malignant degeneration. Chronic ulcer of the stomach is a grave disease, exposing its victim to death by hæmorrhage or from perforation, and it is very difficult to treat. Surgical measures are useless unless the ulcer is located upon the curvatures or the anterior or posterior surface of the stomach. Medical measures, liquid diet and intestinal lavage, must then be resorted to. If the hæmorrhages become abundant, gastro-enterostomy must be performed.

Gazette hebdomadaire de médecine et de chirurgie, April 4, 1901.

Treatment of Spina Bifida by Excision.—M. Broca reports two cases of successful excision of spina bifida. He thinks that the operation is indicated only when the tumor is well protected by normal skin, for only in such instances can the operation be successfully carried out.

Presse médicale, April 3, 1901.

Kernig's Sign in Cerebrospinal Meningitis.—M. A. Chauffard highly commends Kernig's sign as confirmatory of the diagnosis of cerebrospinal meningitis. He regards its elicitation as due to muscular hypertonicity. He defines it as a single or multi-regional contraction, especially striking in the muscular groups which are most functionally active in health, and appearing particularly in attitudes which normally come into play. These attitudes or positions become painful and irreducible pathologically. Kernig's sign is not the only one which can be thus elicited in meningitis, but it is the most complete one and is therefore easy to recognize as a semeiological type.

Wiener medicinische Blätter, March 28, 1901.

Treatment of Pernicious Anæmia.—Dr. Alfred Stengel says that the treatment of pernicious anæmia is divisible into three parts, the specific treatment, treatment directed toward changing the general circulation, and, lastly, treatment of disturbed intestinal conditions which may be the source of the disease. Iron must be given, in the form either of Blaud's pills or of an albuminate of iron. Arsenic is also of great hæmatopoietic value in this disease and should be given in the form of Fowler's solution. If the blood does not improve as the dose is increased, the drug may be given subcutaneously, but gastro-intestinal disturbances and consequent loss of weight must be carefully guarded against. (*To be continued.*)

Wiener klinische Rundschau, March 31, 1901.

Intraperitoneal Rupture of the Bladder.—Dr. Krabel reviews the symptoms and diagnosis between extraperitoneal and intraperitoneal rupture of the bladder, and reports a case which was successfully operated upon.

Contributions to Surgery of the Kidney. By Dr. Josef Preindlsberger. (*Conclusion.*)

Wiener klinische Wochenschrift, March 28, 1901.

Pathology and Theory of Migraine.—Dr. M. Sihle tries to show a pathological resemblance between migraine and epilepsy. The sequelæ of the two ailments are similar. Both are followed by general weakness;

both may be followed by vomiting; and sleep may cause all symptoms of both to disappear. Headache is a sequel of the aura in both diseases, and unilateral paralysis, or even a psychosis, may appear in either disease.

Three Cases of Cataract Following Stroke by Lightning.—Dr. Josef Preindlsberger reports these cases briefly.

Primitive Sight-organs. By Dr. Theodor Beer. (*Conclusion.*)

Riforma medica, February 23 and 25, 1901.

Concerning some Strange Phenomena in Typhoid Fever. By Dr. Umberto Baccarani.—The author discusses the following topics: Delirium and insomnia in the prodromal period; early intestinal hæmorrhages; the palmoplantar sign; the pulsus paradoxus; splenic cough; sialorrhœa; urethritis; desquamation; pruritus, and constipation. He takes as his text the histories of seven typhoid fever patients who had been under his observation during the preceding year, and who presented noteworthy peculiarities in the course of the disease. The average duration of the febrile period was eighteen days, instead of the classic four weeks. There is no doubt that typhoid fever has become less virulent during the last few years, but the cause of this attenuation is not perfectly clear. Perhaps it is due to the improved sanitary conditions, or to the more rational treatment.

Delirium and insomnia are very rare symptoms in the prodromal period of typhoid. The author observed them in one of the cases here reported. These cases may be mistaken for neurasthenia, etc.; but the temperature is a safe guide. Precocious hæmorrhages were observed by the author in one case. The intestinal hæmorrhages in this case appeared five days before any other symptoms of the disease came on. This occurrence has no special prognostic importance, as the case went on in a mild way and ended favorably. The palmoplantar sign, first described in 1897 by Filipovicz, consists of a yellow discoloration of the regions named, and is said to be constant in typhoid. The author found it present in all his cases. The pulsus paradoxus may be observed in typhoid fever, as was evidenced by one of the cases reported by the author. He found that this phenomenon was more clearly evident in the evening, after the fatigues of the day, and was less marked in the morning. This symptom was an indication of a myocardial insufficiency, but was not, in itself, a bad prognostic sign. It might occur in the convalescence.

February 26 and 27, 1901.

Miliary Tuberculosis; Meningitis of Tuberculous or of Typhoid Origin? By Dr. Colla Vittorio.—The difficulty of distinguishing between generalized tuberculous and typhoid infections is admitted by all clinicians. The Widal test is of some assistance, but the author believes that the bacteriologic examination of fæces is of greater positive value. In the present article, the author reports a case in which he used the method of Elsner and Piorowski in examining the fæces of the patient. He concludes that this method of diagnosis is the most satisfactory in doubtful cases.

February 28, 1901.

A Contribution to the Casuistics of the Complications of Diplococcus Pneumoniæ. By Dr. Giovanni

Geronzi and Dr. Rudio Ricci.—The authors report two cases of pneumonia which were accompanied by noteworthy complications. In the first case a meningitis supervened, although the course of the disease had been mild and regular previously: At the autopsy, the heart was found absolutely intact, although meningitis due to diplococci in many cases affects the endocardium. In the second case, the pneumonia was complicated by a septicopyæmia due to the diplococcus. This case illustrates the necessity of making a doubtful prognosis in lobar pneumonia. The localization of the pneumonic process was tardy in both cases.

March 1, 2, 4, and 5, 1901.

Primary Hypertrophies of the Spleen. By Dr. Guido Banti.—The author's conclusions are as follows: There is a group of primary diseases characterized by enlargement of the spleen and by a disturbance of the functional activity of this organ. The first of these is splenic leucæmia, in which the alterations in the morphology of the blood corpuscles are due to changes in the spleen's functions. The other two diseases accompanied by primary hypertrophy of the spleen (primary splenomegalia) are characterized by the development of toxins which are thrown into the circulation by the spleen. These poisons have always a powerful effect on the red blood cells. In splenomegalia with icterus there is a true hæmolytic action. In splenic anæmia and in splenomegalia with cirrhosis the hypertrophy of the spleen is accompanied by an anæmia, the exact mechanism of which as yet has escaped detection. The spleen also develops certain substances that, passing through the liver, sometimes cause fatty degeneration, and sometimes cirrhotic changes, or both. Although the changes in the white cells and the jaundice are observed only in certain types of splenomegalia, the anæmia and the effects on the liver are common to all forms of splenic hypertrophy. It is doubtful, however, whether the cirrhotic changes are common to all forms, or only to certain types.

March 6 and 7, 1901.

The Operative Treatment of Congenital Dislocations of the Hip. By Dr. A. Codivilla.—An experience with seventy-six cases of congenital dislocation of the hip observed in the Orthopædic Institute of Rizzoli, in Bologna, enables the author to formulate the following conclusions concerning the operative treatment of this affection: The bloodless method of reduction is successful, as a rule, in children between the ages of three and twelve years. In exceptional cases this method succeeds in children of from thirteen to seventeen years. The reposition is maintained and the functional results are good in fifty-three per cent of the cases. In the others the luxation recurs, although less marked than at first. In order to avoid recurrence, the limb must be kept in abduction and internal rotation for a long time (four or five months). Osteotomy may be required if the rotation is extreme, in order to reestablish the normal relations of the two ends of the femur. If the recurrence is due to capsular adhesions, or to an absolute defect of the femoral head, a bloody operation will be required. The best incision for this purpose is the antero-external, along the fascia lata. After the operation the incision must be closed immediately, and not kept open with a drain.

Klinitchesky Journal, December, 1900.

(Jubilee Number in Honor of Professor A. A. Ostroumoff, on the Occasion of the Twenty-fifth Anniversary of his Academic Activity.)

Anthrax Pustule in Man. By Dr. L. L. Levshine.—The author records his observations during the past nineteen years on the subject of anthrax, which disease is not uncommon in Khazan. In speaking of the treatment of the pustule he says that he makes a practice of removing the local infective focus, making the incision in the skin two centimetres round the carbuncle, and subsequently cauterizing the wound with Pacquelin's cautery or with solid zinc chloride, and applying an antiseptic dressing. The application of heat not only destroys the microbes encountered by the cautery, but also those bacilli that are found in the parts adjacent to the cauterized tissue. The value of carbolic-acid injections is rather doubtful, as it has been shown that at the moment when the disease is fully developed all the bacilli may have disappeared from the pustule and its environment. It is wrong to use incisions alone without cauterization, for incisions admit air into the tissue and thus make the development of spores possible. Besides, it is important to keep the blood vessels and lymphatics intact, so as to prevent the entrance of bacilli. Absolute rest is indicated because it lessens the movement of the lymph throughout the body and thus antagonizes the spreading of the infection. About 66 per cent. of the author's patients, in whom the pustules had been excised, recovered.

Functional and Organic Changes in the Heart in the Presence of Coronary Embolism. By Dr. A. Vogt.

A Percussion-sign in Dilatation of the Stomach. By Dr. V. D. Schervinsky.—The author describes a new physical sign which he has obtained in some cases of dilatation of the stomach, and which he has not found mentioned in any text-book. It is interesting to note that the author began his observations on the subject after reading an article by Abrams in the *New York Medical Record* for September 8, 1900, in which dyspnœa and pseudo-angina pectoris were spoken of as symptoms of displacement of the heart. In this article Abrams calls attention to the dependence of these cardiac symptoms on dilatation of the stomach and also to the presence of a dull sound on percussion on the left side between the spine and the internal border of the scapula. The area of dulness may be as large as a silver dollar or extend over the whole surface between the spine and the scapula, and this dulness disappears when the patient bends forward. Bronchial breathing is heard over this area. The author cannot confirm the statements of Abrams. In fact, he does not believe that a dilatation of the stomach, pushing up the heart, can compress the left lung to such an extent as to cause dulness behind, unless there is unusual mobility of the heart.

He finds, however, that in dilatation of the stomach a band of dulness from four to five centimetres in width is found in the region of the ninth, tenth and eleventh ribs behind, over which diminished breathing may be heard. The dulness disappears when the patient leans forward, and the sound is absent when dilatation is accompanied by gastroptosis. The dulness is probably due partly to the displacement of the spleen and partly to a condensation of the air in the lower border of the left lung by the stomach, which raises the vault of the diaphragm. Ferber called attention to this symptom a number of years ago, but it has been forgotten.

Clinical Observations on the Action of a Weak Infusion of Canadian Hemp. By Dr. L. E. Golubinine.—The author reports five cases of heart disease in which apocynum was used. He concludes that Canadian hemp is a very valuable remedy in disturbances of cardiac compensation. It is of great service in severe cases in which other remedies fail. It lessens the frequency of the pulse, and this effect lasts as long as its use is continued, while in some less advanced cases the pulse remains slow, even after the remedy is discontinued. The arrhythmia of the pulse is considerably lessened, except in cases with advanced myocarditis. The blood pressure is raised and the excretion of urine markedly increased in patients with dropsy. Albuminuria disappears after the use of apocynum, if dependent upon congestion. The frequency of the respirations is diminished. Five minims of the fluid extract, three or four times a day, is sufficient to produce these effects, and unfavorable effects are almost never present, except slight irritation of the stomach, which disappears if the remedy is interrupted for a day or two, and which may be prevented by giving the fluid extract in combination with the tincture of Indian hemp.

An Attempt at a Biological Theory of the Phenomena of Infection. By Dr. F. A. Grinevsky.—The author devotes a lengthy article to a review of the subject of infection and sums up his conclusions in a table of diseases classified as to their causes.

Tuberculous Pleura-peritonitis. By Dr. P. I. Elistratoff.

Disturbances in Metabolism in Bright's Disease. By Dr. M. A. Kabanoff.

A Case of Gastric Achylia. By Dr. A. P. Langavoi.

The Symptoms and Treatment of Mercurial Angina. By Dr. A. I. Liantz.—Very little has been written concerning mercurial affections of the throat. The author reports the histories of four cases in which there were well-marked affections of the pharynx and tonsils as the result of mercurialism. This affection generally occupies a limited area upon the tonsils and arches of the palate, occasionally penetrating into the lacunæ or extending to the uvula. As a rule, the disease is unilateral, but both sides are sometimes affected. In most cases the gums, cheeks, and tongue remain free from mercurial symptoms. There is pain on swallowing, which is sometimes very acute and spreads to the ear. The submaxillary glands are swollen and painful. Occasionally, the case begins acutely with diffuse redness of the palate and pharynx, fever, vertigo, headache, nausea, etc. Objectively, the disease is characterized by erosions or flat ulcers, covered by grayish-white deposits and surrounded by red and swollen mucous membrane. The ulcers tend to spread laterally and but rarely become deep or leave scars. These lesions may appear at the beginning of a course of treatment with mercury, or even after the drug has been discontinued. The treatment consists in the use of hydrogen peroxide and, in the severer cases, in the application of iodoform emulsion, silver nitrate, or chromic-acid solutions.

The Rôle of the Excretory Organs in Typhoid Fever. By Dr. D. V. Nikitine.

Relapses of Facial Paralysis in Cases with Pre-existing Migraine. By Dr. G. I. Rossolimo.—The author reports a case of recurring facial paralysis in a woman,

twenty-eight years of age, who had been suffering from severe migraines on the left side of the head since puberty. The first attack of paralysis appeared on the left side after an attack of migraine which lasted a week. The paralysis disappeared under appropriate treatment in five months. About two years later, a second attack of migraine on the right side was followed by facial paralysis on the same side. The third attack was a repetition of the second, and appeared six months later. There had been no rheumatism and no infectious disease. The fourth attack consisted of migraine and paralysis on the left side. The ætiology of the paralysis is not clear, but there is probably some connection between the hemi-crania and the paralysis of the seventh cranial nerve.

Edema in Diabetes Mellitus. By Dr. N. G. Titoff.—Edema may occur in diabetes mellitus: (1) As the result of anæmia, and is then to be treated with preparations of iron; (2) due to weakness of the heart's action, to be treated by rest and stimulants; (3) due to self-intoxication—distinct from that causing coma—to be treated by diet and diaphoretics; (4) due to cachexia, to be treated by improvement in the general condition.

The Hot Springs in Brusa and Jaloff. By Dr. V. P. Tschepotzeff.—A description of these ancient hot springs in Asia Minor, with analyses of the water in both places. These mineral springs may be classed partly as indifferent, partly as sulphurous, and resemble the waters at Aix-les-Bains, Gastein, Toeplitz-Schoenau and Wildbad. Both watering places are not far from Constantinople and have begun to enjoy considerable popularity of late.

The Rôle of the Clinic in Modern Pathology. By Dr. V. A. Vorobjeff.

Scottish Medical and Surgical Journal, February, 1901.

The Relation of Dentistry to Medical Education. By Dr. W. H. Williamson.—A presidential address.

Pulmonary Phthisis and its Treatment. By Dr. A. James (*continued*).—The prognosis in phthisis can be best considered under the following heads. 1. Conditions of heredity. Double heredity is worse than single, the younger members of a family are more likely to suffer from bad heredity than the elder, and the members of a family resembling the weaker parent are more prone to a similar weakness. 2. Conditions which have led to the development of the disease. The more unfavorable the circumstances have been, the better chance has proper treatment of procuring an arrest in the phthisis, and the greater the possibility of permanently improving the circumstances, the greater the possibility of permanent recovery. 3. General condition of the patient. The better this is, the better the prognosis, and under this head the most important feature is fever. 4. Condition of the lungs. An early involvement of both apices indicates a rapid course. In the very chronic examples of phthisis, the limitation of the disease to one lung is characteristic. 5. Complications. These add enormously to the gravity of the disease, and notable amongst them are tuberculous laryngitis and enteritis.

In the treatment of phthisis the idea is to put the patient, as it were, back in civilization; to put him in surroundings where humanity is sparse, where air is pure, where freedom of movement, of body, and of lungs is as absolute as possible, and where sunlight is abundant. For many patients these conditions are difficult to obtain, and in such cases the author is strongly in favor

of sanatorium treatment as opposed to "home" treatment. The sanatorium simply offers in convenient combination all facilities for treatment. The author closes by reviewing the hygienic, dietetic, and medicinal treatment of phthisis. As regards baths, the systematic application of cold is of great use. If the cough is really troublesome, an intralaryngeal injection of menthol in parolein (twenty-per-cent. solution and one half drachm to be injected) should always be tried. In all cases of hæmoptysis the condition of the bowels should be looked into, and any constipation at once relieved. For the fever, we must trust to absolute rest, open air, and feeding. Cod-liver oil should always be given, wherever possible, combined with a few drops of the liquor arsenici hydrochlorici.

A Short Note on Bilharzia Hæmatobia, and Notes of Three Cases. By D. Wallace, F. R. C. S. Ed.—The habitat of the *Bilharzia hæmatobia* in the human subject is chiefly the portal vein and its branches. That an intermediate host is probable is acknowledged, but as yet none has been discovered, although the general opinion is that it is a mollusc of some kind. The ova are mainly found in the urine. Hæmaturia is the salient symptom in those who are infected by the parasite, and the condition is commonly termed bloodwater or blood-gravel. A sequel or concomitant of the affection is occasionally a renal or vesical calculus. How the parasite gains access to the human body is not known. The author has seen three cases of the affection, in all of which the ova were readily seen when a blood-clot was examined for them. When the urine was clear no ova were to be observed. In the majority of cases the disease gradually disappears of itself. It is not the rule for others than adolescents and young adults to suffer.

The Bacillus Coli Communis in Relation to Cystitis. By Dr. K. M. Douglas.—The conclusions reached by the author are as follows: 1. The *Bacillus coli communis* is met with in the great bulk of cases of cystitis, and, in many, is the determining cause of the disease. 2. In certain cases, the organism is abundantly present during long periods in the bladder, under favoring conditions, but without causing cystitis. 3. Certain of the facts lend support to the view that often the bacillus is a supplanter of other forms rather than the irritating cause of the disease. 4. The marked polymorphism and varying pathogenicity of the organism would account for the conflicting opinions held regarding its identity and its rôle in cystitis, and the confusion of nomenclature until recently prevailing. 5. No one culture reaction enables the organism to be with certainty recognized, but cultivation on several media is needful.

A Curious Case of Disordered Cerebral Circulation. By P. G. Borrowman, M. B.—The author reports the case of a boy, aged nine years, who was in the habit of standing on his head for quite long periods of time. After the last occasion of his doing so, he developed headache and nausea, and went to bed. During the following six weeks he slept almost constantly night and day. Nothing could be made out on physical examination beyond dilatation of the pupils and weakness of the heart's action. Tincture of digitalis was ordered, and within a month he was apparently perfectly well.

A Case of Pseudohypertrophic Muscular Paralysis. By G. Rose, M. B.—The author gives a most careful and thorough report of a case of this affection. The article is accompanied by a series of most excellent photographs showing most graphically the patient's manner of rising from the recumbent to the standing position.

Sections of the affected muscles showed the connective tissue between the muscle fibres to be very much increased and highly nucleated. There were also large deposits of fat between the muscle fibres, but the latter appeared to be comparatively healthy.

A Clinical Note on a Case of Eclampsia at the Sixth Month—Recovery—Successful Labor at Full Time. By Dr. M. Dewar.

Book Notices.

Text-book of Physiology. Edited by E. A. SCHÄFER, LL. D., F. R. S., Professor of Physiology, University of Edinburgh. Volume Second. Pp. xxiv-1365. Edinburgh and London: Young J. Pentland. New York: The Macmillan Company, 1900.

THE first volume of this important work, written by a number of English physiologists under the editorship of Professor Schäfer, appeared two years ago and was reviewed in this journal at that time. As the second volume completes the work, it is now easier to form an estimate of the undertaking as a whole. As was explained in the former review, the book is not a text-book in the ordinary sense of the word, but rather a handbook. It is written on the same general plan as Hermann's *Handbuch der Physiologie*, which was published twenty years ago; since the publication of that work nothing similar has appeared in any language, and it is very probable that for many years to come this text-book will be looked upon as the great storehouse of information on physiology, just as Hermann's *Handbuch* has been for the last two decades. Hence the work may be regarded as the expression of the ideas of the leading English investigators as to the present scope of physiology. Viewing it from this standpoint, we must confess that the first feeling is one of disappointment. No effort seems to have been made to secure completeness. The subjects of generation and reproduction, for example, are omitted entirely "because they are studied almost entirely by morphological methods," an argument which would apply almost equally well to a considerable part of the sections on the sympathetic and central nervous systems. Even if it is granted that it is desirable to make a distinction between "general physiology" and what may be called the "conventional physiology" (a distinction which would be regretted by many), there are surely many facts connected with fertilization and with the nutrition of the embryo which the physiologists can ill afford to surrender entirely to other workers. No one will regret the incorporation of a chapter on the physiology of the electrical organs of fishes, especially as it is written in a very interesting way by such an authority as Gotch, but there are other subjects in comparative physiology which are equally entitled to a consideration in such a work as this. All that is said about the physiology of sleep is contained in a line or two in a footnote dealing with the processes of nerve cells, *i. e.*, with facts (or theories) reached by purely morphological methods; the interesting and important experiments of Mosso, Howell, and Kohlschütter are entirely ignored. With the exception of a short paragraph on the electrical response, nothing is said about the physiology of unstriated muscle.

The want of completeness which characterizes the work as a whole is also very conspicuous in some of the different chapters; some of the writers have used their opportunity largely to record their own work and to de-

velop their own views, rather than to give a uniform discussion of the subject as a whole. This attitude gives a decidedly provincial, or rather insular, stamp to parts of the work. Regarded as an exposition of modern physiology, this text-book is hardly the equal of the *American Text-book of Physiology*, although the latter is intended to be simply a text-book for medical students, while the former is written for advanced students and specialists.

While, as is natural in dealing with such an extensive work as this, the defective parts are the first to attract attention, closer examination shows that the treatment of many subjects is worthy of only the highest praise; in fact, it is probable that some chapters will become classic in English physiology. In any case it is a work which no one who desires to be informed on recent work in physiology can afford to be without.

Only specialists in the various fields of physiology could give just and really valuable criticisms of the various chapters, but the following sketch may give a general idea of the subjects treated in this volume. The first chapter deals with the mechanism of the circulation of the blood and is written by Leonard Hill; the subject is treated in the usual way, and the article calls for but little comment. The work of Hales receives somewhat fuller recognition than is usually the case in such articles, and special attention is called to the effects of posture upon the blood pressure and to the cerebral circulation—subjects with which the name of Hill is so closely associated. The second chapter, on the contraction of the cardiac muscle, by Gaskell, is one of the most interesting parts of the volume. It is nearly twenty years since Gaskell began to call attention to the importance of the cardiac muscle in the origination of the heart-beat, but it is only recently that his views have become generally accepted, especially on the Continent, and their importance recognized alike by physiologists and physicians. Hence it is especially interesting to have at this time a lucid account of the development of his views and their relation to the earlier theories of the heart-beat. Unfortunately, however, the chapter contains little but the discussion of this phase of the subject; the treatment of the nutrition of the heart, and especially the recent work on the mammalian heart, receive very inadequate consideration.

Animal mechanics is discussed by Haycraft, while the muscular and nervous mechanisms of the respiratory movements, and of the digestive, urinary, and generative apparatus are described by Starling. The treatment of these subjects is excellent throughout; the advances, however, in our knowledge of these topics in the last few years have not been very great in comparison with those in some other fields of physiology. The recent work on the innervation of the bronchial muscles and of the genito-urinary apparatus and of the movements of the oesophagus and stomach as revealed by the Röntgen rays is introduced.

The mechanical, thermal, and electrical properties of striped (including the cardiac) muscle are discussed in rather technical language by Burdon Sanderson. We are referred to the first volume for a discussion of the chemical changes accompanying muscular contraction; yet, on examination, we find but a single page devoted to this subject, although this deficiency is met to some extent by a rather full discussion of proteid metabolism. The recent experiments on the relation of various kinds of foods to muscular work and fatigue are scarcely mentioned.

There is little to be said in criticism of the remaining chapters of the book: they have been written by men emi-

nent for their researches and for their breadth of view and knowledge. The physiology of the nerves and of the electrical organs is discussed by Gotch, and that of the nerve cells by Schäfer. The chapter by Langley on the sympathetic and other related systems of nerves is the best account of the anatomy and physiology of these systems which has yet appeared; the same may be said of Schäfer's article on the cerebral cortex and of Sherrington's chapters on the spinal cord and the parts below the cerebral cortex and on cutaneous sensations and the muscular sense. These sections will interest the anatomists and neurologists quite as much as the physiologists. The articles on the special senses have been written by Rivers (vision), M'Kendrick and Gray (hearing), and Haycraft (taste and smell). M'Kendrick and Gray also contribute a chapter on vocal sounds.

The book is exceptionally well printed and bound. There is an index of subjects and one of authors; a few errors are noted in the latter, as was also the case with the first volume. Thus, Howell's name appears in one place as "Howell" and in another as "Howells"; two authors of the same name (*e. g.*, Stewart) are not always distinguished by their initials in either index or text. Such small oversights are to be regretted, as it is not probable that a new edition of such a large work will be issued for many years.

Air, Water, and Food from a Sanitary Standpoint. By ELLEN H. RICHARDS and ALPHEUS G. WOODMAN, Instructors in Sanitary Chemistry, Massachusetts Institute of Technology. First Edition. First Thousand. Pp. 226. New York: John Wiley & Sons, 1900.

IN this volume the authors consider these three vital necessities of human life in their sanitary and hygienic relations. The impurities existing in water supplies, the atmosphere, and the ordinary foods are pointed out, and the many methods of analysis and determination of these noxious elements are given in detail. These features form the scientific part of the book, which does not overshadow, however, the practical points. The chapter on ventilation, for instance, is an exceedingly practical piece of writing, as is that on food adulteration.

At the present time, when hygienic and sanitary considerations are influencing so powerfully the life of the people and the thought of the physician, a work of this kind, carefully digested as it is, and full of valuable hints and suggestions, cannot fail to be of value. In temperate, conservative works of this nature the profession will find much of didactic worth.

A Manual of Personal Hygiene. Edited by WALTER L. PYLE, A. M., M. D., Assistant Surgeon to Wills Eye Hospital, Philadelphia, etc. Illustrated. Philadelphia: W. B. Saunders & Company, 1900. [Price, \$1.50.]

THIS little work aims to promote right living, based on physiological principles; and it is very safe to say that, if the principles enunciated were observed by mankind in general, the medical man's income would be materially lessened.

The book consists of separate essays on the hygiene of the various parts of the body. Dr. Charles G. Stockton writes on the digestive apparatus, Dr. George H. Fox on the skin and its appendages, and Dr. E. Fletcher Ingals on the vocal and respiratory apparatus. The ear is considered by Dr. B. Alexander Randall, the eye by

the editor himself, the brain and nervous system by Dr. J. W. Courtney, and physical exercise by Dr. G. N. Stewart.

The work contains such a mass of detail that a review of the contents is scarcely possible. The book is a safe one to put into the hands of the laity, for it is scientifically sound, and it is a good guide for the practitioner who wishes properly to instruct his patients in the manner in which they should live. It abounds in sound advice and good principles.

A Medico-legal Manual. By WILLIAM W. KEYSOR, Lecturer on Medical Jurisprudence in the Omaha Medical College, etc. Pp. 316. Omaha: Burkley Printing Company, 1901.

THIS little work should be a welcome addition to the library of every physician liable—and which one of us is not, at times?—to be called to give evidence professionally in a court of law. It differs from the ordinary text-books on medical jurisprudence in the fact that it essays to teach the physician the principles of law involved in such questions as those upon which he may be called upon to give evidence, rather than to teach him those facts of medical science which usually fill the pages of the latter class of treatise and which he should be able to learn from ordinary text-books. In other words, it is a book written by a lawyer for physicians, rather than a book written by a physician for lawyers. Both kinds of works are necessary to uncover the Janus-like countenance of legal medicine.

This work is divided into thirty-two chapters, and deals clearly but concisely with such subjects as evidence, life insurance, insanity, delirium and dreaming, what constitutes a mind in law, identification of persons, marriage and divorce, fruits of cohabitation, etc. It does not conflict, but rather takes a collateral place, with Mr. Taylor's excellent little manual, *The Law in its Relation to Physicians*. This latter work teaches the physician what is the attitude of the law to him under certain contingencies; the present work is designed to point out to him what is the proper attitude for him to assume toward the law in cases in which he is called upon to bring his scientific knowledge to its aid.

Ueber das Intubationstrauma, von Dr. JOHANN VON BÓKAY, A. O. Universitätsprofessor, etc., Buda Pesth. (Sonderabdruck aus der *Deutschen Zeitschrift für Chirurgie*, 58. Band.) Leipzig, 1901.

THIS book of 109 pages, with 7 plates—a reprint of the author's contribution to the fifty-eighth volume of the *Deutsche Zeitschrift für Chirurgie*—is of peculiar interest to Americans. It is difficult to find a page in it that does not refer to Joseph O'Dwyer's immortal achievement. Its several chapters treat of (1) the traumatism caused by the introduction of the tube, (2) that which results from its retention in the larynx, (3) that which is caused by extubation (to which is attached a discussion of the hoarseness following intubation), and (4) the cicatricial strictures and obstructions of the larynx after intubation. Even those who have much experience on these points will find additional information in the famous author's practical and literary studies. The book is dedicated to the "president of the New York Academy of Medicine in that memorable meeting (June 2, 1887) in which O'Dwyer and his collaborators, Francis Huber, Dillon Brown, W. P. Northrup, I. H. Hance, and A. Caillé, first made intubation thoroughly known."

A Reference Handbook of the Medical Sciences, embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By various writers. A New Edition, completely Revised and Rewritten. Edited by ALBERT H. BUCK, M. D., New York. Volume I. Illustrated by Numerous Chromolithographs and Four Hundred and Ninety-eight Fine Half-tone and Wood Engravings. Pp. x-799. New York: William Wood & Company.

THIS work is far too well known and too highly esteemed to require description or criticism at this day, but it cannot but be a source of satisfaction that the advance in medical knowledge should be kept pace with in this work by a thorough revision and a new edition rather than, as was done in 1894, by the publication of a supplementary volume. Such addenda are never satisfactory, for obvious reasons. From an examination of the first volume of the rejuvenated work it is evident that the reconstruction is to be thorough, and nobody can examine the volume without being struck by its completeness and very great value. It is encyclopædic in the best sense.

The Microscopist's Vade-mecum. A Handbook of the Methods of Microscopic Anatomy. By ARTHUR BOLLES LEE. Fifth Edition. Pp. xiv-532. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$4.]

IT is probable that no one interested in microscopy is without a volume of Lee's book in his library. In a few years it achieved such a reputation as a unique exposition of the principles and methods of histological work that successive editions have been speedily absorbed. In the present edition the author has omitted many of the antiquated and now useless methods, and has taken occasion to amplify the theory of the principles involved.

There is nothing in the whole realm of microscopical work that is not included in Lee's book, from the killing of the protozoa to the most minute description of modern neuropathological methods. The bibliographies attached to the various sections enhance the value of the individual chapters, rendering reference easy. In fact, no one interested in microscopical technics can afford to be without this indispensable work. It is a veritable *vade-mecum*.

BOOKS, ETC., RECEIVED.

International Clinics: A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pædiatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession throughout the World. Edited by Henry W. Cattell, A. D., M. D. Volume I. Pp. viii-312. Eleventh Series, 1901. Philadelphia: J. B. Lippincott Company, 1901.

Human Placentation. An Account of the Changes in the Uterine Mucosa and in the Attached Foetal Structures during Pregnancy. By J. Clarence Webster, B. A., M. D. (Edin.), F. R. C. P. E., F. R. S. E., Professor of Obstetrics and Gynæcology in Rush Medical College, etc. Pp. 126. With 233 Illustrations. Chicago: W. T. Keener & Company, 1901.

An Index of Symptoms as a Clew to Diagnosis. By Ralph Winnington Leftwich, M. D., Late Assistant Physician to the East London Children's Hospital. Second

Edition. Pp. xvi-267. New York: William Wood & Company, 1901.

Chronic Urethritis of Gonococccic Origin. By J. de Keersmaecker, Chief of Service, Diseases of the Urinary Organs at the Centraalkliniek of Antwerp, and J. Verhoogen, Agrégé at the University of Brussels, etc. Translated and Edited, with Notes, by Ludwig Weiss, M. D., Attending Physician to the Genito-urinary and Skin Service, German Poliklinik, etc. Pp. xiv-263. New York: William Wood & Company, 1901.

First Aid to the Injured Ambulance Drill. By H. Drinkwater, M. D. Pp. 104. New York: Macmillan Company, 1901.

Hygiene and Public Health. By Louis Parkes, M. D., D. P. H. (Lond.), Lecturer on Public Health at St. George's Hospital Medical School, etc., and Henry Kenwood, M. B., D. P. H., F. C. S., Assistant Professor of Public Health at University College, London, etc. Pp. xix-732. With Illustrations. London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$3.]

3,500 Questions on Medical Subjects, arranged for Self-examination. With the Proper References to Standard Works in which the Correct Replies will be Found. Third Edition, Enlarged. With Questions of the State Examining Boards of New York, Pennsylvania, and Illinois. Pp. viii-9 to 229. Philadelphia: P. Blakiston's Son & Company, 1901.

Tuberculosis as a Disease of the Masses, and how to Combat it. Prize Essay by S. A. Knopf, M. D. Pp. 86. New York: M. Firestack, 1901.

Miscellany.

A Chinese Xiphopagus.—Dr. Edouard Chapot-Prévost, of Rio de Janeiro (*Gazette médicale de Paris*, March 23, 1901), communicated recently to the Paris Academy of Medicine an account of Liou-Tang-Sen and Liou-Seng-Sen, twins born in China in January, 1887, connected by a sternal band, being the eleventh known living instance. They were being exhibited by the Bannum-Bailey syndicate at Vienna. The father was eighteen years of age, and the mother twenty, at the time of marriage. There was no instance of twins in the family of either parent. The pregnancy took place in a level country, but slightly elevated above the sea, not mountainous as has been the case in most other instances of the kind. The father was the only attendant at the accouchement, which was easy, notwithstanding the nature of the case and the fact that the mother was a primipara. The first presentation was cranial, the second a foot presentation. There was only one cord and one placenta. Each child was slightly under the average size at birth. The mother had no miscarriage and no other pregnancies. She died three years after their birth.

The children were breast nourished for two years and a half. They began to talk at a year and a half, but did not begin to walk till three years of age. They are very intelligent. They can lie indifferently on either side. They had small-pox at four years of age, one sickening one day before the other; this one alone bears any small-pox marks. In disposition they are mirthful, very fond of each other, and not quarrelsome. As to locomotion, when Liou-Seng-Sen is on the right and Liou-Tang-Sen on the left, they can walk forward side by side, in a manner somewhat similar to that of two men forming what is known as a "two-handed seat" for carrying the wounded. In this position they can walk easily, and even run and leap. When they change position, however, so that Liou-Tang-Sen is on the right and Liou-Seng-Sen on the left, they cannot walk regularly, but are obliged to make one foot follow the other in the same direction for the movement of progression. In the first case, both walk forward; in the second, sideways, one going from left to right, and the other from right to left. Liou-Tang-Sen is 53½ inches tall and Liou-Seng-Sen 52¾ inches. Each was sixty pounds when last weighed. All their functions are independent. In each, the urine is vari-

able both as to time and quantity. One may sleep while the other is awake. One is sometimes hungry when the other is not. On one occasion, whiskey was given to one of them only, when both became intoxicated, the one that had not taken the whiskey being more drunk than the other.

They are united in front by a fleshy band, seven centimetres and a half long and three centimetres broad, which is situated in both of them at the lower border of the sternum. The x-rays show that the band has no bony part; but the peritonæum of each is to be seen within it.

Paralysis in Typhoid Fever.—Dr. James Carslaw (*Glasgow Medical Journal*, March) recently reported to the Glasgow Pathological and Clinical Society two cases of paralysis in typhoid fever; the first he regards as a true complication of typhoid fever, due to the effect of the toxins of the *Bacillus typhosus* on the nervous tissues; the second he regards rather as a coincidence—an attack of hemiplegia in the course of typhoid, which might have occurred in connection with any feverish illness, or even without any other symptoms. The author says:

“Apart from the nervous symptoms, such as headache, sleeplessness, and delirium, that occur in enteric fever, as in some of the other specific infectious fevers, there are many definite affections of the nervous system that may develop either during the fever or in the course of convalescence. In this respect enteric resembles epidemic influenza more than any other of the specific fevers. There may be mental symptoms, leading on to some form of insanity, or neurasthenic conditions may supervene. But there may also be definite system disease of the brain or of the spinal cord, or some inflammatory affection of the peripheral nerves. Cases of hemiplegia have been recorded by Murchison and others, and, though they may sometimes be due to embolism, it is said that hemiplegia may occur from arterial thrombosis, just as such thrombosis may occur in a limb and lead to gangrene. Disseminated sclerosis, disseminated myelitis, and anterior poliomyelitis have all been found as sequelæ, but the paralysis of enteric fever is probably most frequently due to a neuritis. This may be a slight affection, and in this form is probably not very infrequent, perhaps limited to the feet, and giving rise to the so-called ‘tender toes of typhoid’; or it may be very extensive—affecting all the limbs, and associated with marked atrophy in addition to motor and sensory disturbances.”

The first case, that of a young man twenty years of age, showed asymmetrical peripheral neuritis of both upper limbs. He had three weeks of grave fever with constant delirium and unconsciousness, and about a week later there developed severe pain in the right arm and especially at the shoulder, with numbness in the fingers. followed in two days by practically complete paralysis of the arm. Two weeks later the left arm followed suit. There was no history of venereal disease or rheumatism. The patient was temperate and had always enjoyed good health. Nothing abnormal in face, eyes, or tongue: knee-jerks slightly exaggerated. The right deltoid was much more wasted than the left, while the right biceps was in good condition and the left much wasted. There was pain on handling the affected muscles. The forearm muscles, especially the extensors, were very weak, and there was drop-wrist. There was an area on the right hand and forearm, including the right thumb and first two fingers, the outer half of the palm of the hand, the outer half of the back of the hand and for a distance of about two thirds up the back of the forearm on its radial aspect, where there was marked anæsthesia of tac-

tile impressions. In the same area there was analgesia, loss of thermal sensibility, and absence of muscle sense, while this region was quite dry and cold, the other hand and the remainder of the right hand being flushed and perspiring. Tactile sensibility was good elsewhere, and there was, particularly in the left hand and arm, hyperalgesia to such an extent as to render it somewhat difficult to make a detailed electrical examination. There was some tremor of the limbs, and the muscles were unusually sensitive to direct stimulation. A biceps-jerk was easily elicited on the right side, but otherwise the reflexes of the arms were absent. There was some swelling of the hands, which might be partly mechanical in connection with the wrist-drop, though it might be related to the vasomotor disturbance evidenced by the flushing and perspiring. In regard to the electrical reactions, the reaction of degeneration was present in all the muscles of both shoulders and arms, though the increased sensitiveness of the patient made it difficult to state the results in figures. The method of treatment adopted was the application of the faradaic current to the muscles that responded to it, but the galvanic current to those that responded only to it. Considerable improvement had taken place.

Luxation of the Testicle.—M. Parizeau (*Union médicale du Canada*, February, 1901) records a curious case of luxation of the testicle. The patient, a man sixty-four years of age, was working at an excavation when he was buried in a mass of débris. On being released, he was almost asphyxiated, and the subject of many contusions. On recovering from a semi-comatose condition, he complained of intolerable pains on the left side of the thorax, which were only partly relieved by the discovery and treatment of three fractured ribs. He suffered much from shock, being pale, with a rapid and feeble pulse, frequent and painful respiration and repeated and prolonged vomiting far into the night. Active stimulation had ameliorated his condition by morning, when he was first seen by Dr. Parizeau. About a fortnight later, the patient drew the doctor's attention to a soft, regularly oval, almost painless swelling on the inferior surface of the penis, the skin about which was ecchymosed and to which, taking it for a hæmatoma, he at once applied a moist compressing dressing. The scrotum appeared to be normal. After the swelling had subsided, examination convinced the author that this swelling was a dislocated testicle, of the absence of which from its proper place he soon satisfied himself. At the earnest solicitation of the patient he incised the scrotum obliquely toward the root of the penis, and releasing the imprisoned testicle from the eicatricial mass by which it was retained, replaced the errant gland and fixed it *in situ*. A perfect recovery was made without any accident, and after the expiration of many months there had been no atrophy.

There had been, the author said, up to that date two cases of luxation of the testicle recorded: in the first, by Hess, the testicle had lodged in the opposite side of the scrotum, having passed through the sæptum: in the other, by Bruns, it had been found underneath the skin of the pubes.

Leprosy on the Canary Islands.—The existence of about 200 lepers on the island of Teneriffe, Canary Islands, has been officially reported at Washington by United States Consul Berliner. He says that there are three distinct classes of leprosy on Teneriffe Island, namely, *lepra arabum*, *lepra elephantiasis*, and *lepra*

tuberculosis. The disease diverges into two main varieties, the spotted and the nodular. The report is based on personal investigation and assistance of physicians, and says: "As being contagious, it is generally discredited here, but, in my opinion, it is very infectious. In former years Spain had established a colony at Grand Canary for lepers. They were housed there, but had perfect liberty to wander about with the restriction that they must sleep at the houses built for them. In course of time this law became a dead letter, and gradually they spread over the different islands. At Santa Cruz de Teneriffe, the capital, there are (from personal knowledge) 22 lepers, 15 of whom are men, and there are also some children of these unfortunates. Officially it is not recognized that leprosy exists on these islands." United States Consular Agent Swanson, on Grand Canary Island, in an accompanying report, says that leprosy there is decidedly decreasing. There are fifty patients in the lepers' hospital at Las Palmas. A few families infected with the disease live in their own homes.

The Treatment of Dry Labor.—Dr. Atlee (*American Journal of Obstetrics*, March) says that before recalling the various means we can employ for the relief of this condition, he would say with Lusk, that with increasing experience his own practice has grown more and more conservative, and his belief is that true wisdom requires us to abstain from even trivial operations *so long as Nature is able to do her work without our assistance.*

Should the os dilate very slowly or not at all, and the woman be suffering great pain, she must be relieved by some means, for this element of pain is much to be dreaded, as, when long continued, it is a powerful nerve depressant. "When combined with starvation and deprivation of sleep, it greatly impairs a woman's powers to resist the perils of the puerperal period." In this condition a prolonged warm bath, an enema of twenty grains of chloral in six ounces of warm milk, or a hypodermic of one quarter of a grain of morphine, will often act like a charm; and, again, the relief will be only very temporary, lasting perhaps half an hour. We then resort to mechanical means to assist the dilatation of the os, by means of trying to keep the woman on her feet. When the pains are very severe and almost continuous, as they so frequently are in this condition, it will be impossible for her to do so; Barnes's water-bags may then be tried, as they both dilate the os and increase the efficiency of the pains. However easy it may be to advise their use, in the case here recorded great difficulty would have been encountered in introducing them into the os so high up and behind the vertex. That it could be done by dexterity and perseverance Dr. Atlee does not doubt. He would have placed the patient in the knee-chest position and gently pushed the presenting part out of the way, and at the same time facilitated the operation by the use of Sims's speculum.

After the complete dilatation of the os the forceps is the safest and surest means at our disposal; for, by the use of ergot under these circumstances, with the uterus probably in a state of tetanic contraction, applied closely to the child, we should only increase the retraction, while not increasing the contracting or expulsive efforts. The forceps, in the form of the narrow-bladed Taylor's instrument, has been suggested even before the os is dilated and the head engaged, but, except in the hands of the most skilful accoucheur, to apply it to the movable head is a very difficult and hazardous undertaking. With

the os dilated and the head engaged, the application of the forceps nowise differs from its use under any other indications, and should be performed *secundum artem.*

Congenital Dislocation of the Patella.—At a meeting of the Section in Orthopædic Surgery of the New York Academy of Medicine, held on March 15th, the chairman, Dr. George R. Elliott, showed a man, twenty years old, with dislocation of the right patella. His relatives had told him that it was first noticed two days after his birth; he had worn apparatus at various times, but nothing since 1888. The patella slipped into place on extension, but on flexion slid over the external condyle of the femur, even if force was applied to hold it; there was two inches of atrophy of the right thigh; a slight degree of knock-knee existed. All that the patient complained of was a sense of weakness and uncertainty in the leg. The man wished to know if the condition could be remedied without leaving him with a stiff knee. He preferred his condition of slight disability to a stiff leg.

A Case of Fracture of the Seventh Vertebra.—At a meeting of the New York Neurological Society, held on April 2d, Dr. Edward D. Fisher reported the case and presented the specimen. The patient was an acrobat, twenty years of age, who, while turning a somersault from the shoulders of a companion, had fallen a distance of about five feet, and struck on his head. He was instantly paralyzed. When he was seen by the speaker, that evening, there was complete anæsthesia extending from below the nipple to the armpit, and on the inner side of the arm and forearm, and taking in the ring and little fingers. There was complete loss of motion, and there was paralysis of the bladder and rectum. The reflexes, superficial and deep, were completely lost. Permission could not be obtained for an operation until three days later, and in the meantime there had been a temperature range of 104° to 105° F. The operation was done by Dr. B. Farquhar Curtis under cocaine anæsthesia, and the laminae of the fifth, sixth, and seventh vertebrae were removed. No evidence of injury to the cord could be discovered. The man died three days later. The autopsy revealed a fracture of the body of the seventh vertebra. There was no subdural hæmorrhage, but there was marked softening of the cord at the seventh cervical segment. There was very little gray matter left in the cord at that level, and there was very little evidence of hæmorrhage into the cord proper. A very prominent symptom had been the extreme pain experienced along the course of the nerves.

The Japanese as Surgeons.—Dr. E. C. Register (*Indian Lancet*, March 11th), writing from Nagasaki, in an article on The Hospitals of Japan, says:

"In surgery the smaller and more delicate and difficult the operation is the more it interests. The average Japanese physician would rather see a cataract operation than a hysterectomy. To watch them prepare for an operation, the time they seemingly throw away arranging little things, the minute instructions they give their assistants and nurses, even in minor surgical cases, and to observe them fix, with so much care and deliberation, every table and tray, every knife and sponge, perfectly oblivious to time, is as amusing as it is tiresome to the hustling, restless, and impatient American."

We are by no means sure, however, that "the hustling, restless, and impatient American" would not do well to learn a lesson from the careful and deliberate Jap.

Special Articles.

ABDOMINAL PAIN IN TYPHOID FEVER.

(From the Service of Dr. Osler, the Johns Hopkins Hospital.)

By THOMAS McCRAE, M. B.,

BALTIMORE,

INSTRUCTOR IN MEDICINE, THE JOHNS HOPKINS UNIVERSITY;
ASSISTANT RESIDENT PHYSICIAN, THE JOHNS
HOPKINS HOSPITAL.

If the question were put to a number of practitioners, "How often does abdominal pain occur in typhoid fever?" it is probable that very varying answers would be obtained. The student, if pressed for an answer, would fall back on his text-book and probably reply that it occurred only with certain complications, especially perforation, for the majority of text-book articles make little mention of abdominal pain in typhoid fever except in complications. One exception is the article by the late Dr. Pepper, in the *American System of Medicine*, in which the statement is made that abdominal pain and tenderness are commonly present. Reference is always made to tenderness in the abdomen and especially in the right iliac fossa.

It is not necessary to establish the importance of an accurate knowledge of the occurrence of this symptom. This is, of course, greatest in connection with the diagnosis of perforation, of which pain is the most constant symptom. Only by early recognition of this complication can we hope to save perhaps one of the two patients with perforation in every hundred typhoid cases. Typhoid fever is becoming more and more a disease which is treated in hospitals. The recognition and estimation of serious abdominal symptoms must often depend on the house physician. For him is especially necessary an accurate knowledge of the various conditions causing abdominal pain. The question of the cause of pain may arise suddenly, other symptoms may be contradictory or deceptive, and the decision as to the occurrence or not of perforation may be most difficult. Special attention to the necessity for careful systematic study of these cases has recently been drawn by Dr. Osler (1). The strain of deciding the question of diagnosis in doubtful cases is very great. Early operation in perforation is all-important. Of course a needless exploration for suspicious signs is to be avoided if possible, although with recent methods the risk has been much reduced and is often less than leaving a doubtful case alone. The same applies to rarer abdominal complications, such as cholecystitis or appendicitis.

The occurrence of five cases of perforation in typhoid fever in about as many months in the medical service of his hospital has necessarily again drawn our attention forcibly to its symptoms and recognition. Several other cases during the same time were under both medical and surgical observation, the abdomen being opened in four, one of which was acute appendicitis, one was liver abscess, and in the other two no lesion was found. In all

of these abdominal pain was a prominent symptom. To obtain a definite idea of its occurrence, the last 500 cases in the hospital have been studied with reference to this symptom. The majority of these have been under personal observation.

Before giving the results of this series, it is of interest to note a few of the references in the literature. As a general rule, little mention is made of this symptom. The statement of Pepper is noted before. Wilson (2), in one article, says: "Abdominal tenderness and pain are present in the majority of the cases." In another article this same writer (3) says that "abdominal tenderness may be elicited upon gentle pressure in the majority of cases" and "spontaneous abdominal pain is not common. It may arise, however, in consequence of extensive or deep ulceration and is present in local peritonitis." Moore (4) states that "there is tenderness on pressure over the abdomen," but he makes practically no mention of pain apart from perforation and peritonitis. The middle ground is taken by Murchison (5), who says: "Abdominal pain and tenderness are common but not necessary symptoms." He quotes tenderness as being present in 71 out of 81 of his own cases, in 106 out of 127 in a series of Louis's, and in 15 out of 20 fatal cases reported by Jenner. This statement of Murchison's has been widely copied and translated into foreign articles. In Strümpell (6) it is said that "abdominal pain is often entirely absent. Some, however, complain of abdominal pain throughout almost the entire illness." Tenderness is thought by him to be most marked with constipation. H. A. Hare (7) considers that "pain in the abdomen is distinctly a symptom of the early stages, and in many cases is due to gas. It is usually wandering and is not consequently in one spot; if so, it probably depends on localized complication. Often there is some pain later when there is tympanitis and distention." Melville (8), in reporting the abdominal features of 250 cases seen in India, found pain in 88 at some period. The general idea in the literature generally is that pain is of no special significance apart from the complications.

The 500 cases of this series may be classified under three headings as regards pain:

I. Cases without pain or tenderness at any time during the attack. Of these there were 206, or 41 per cent.

II. Cases with tenderness but no pain. Of these there were 72, or 14 per cent.

III. Cases in which abdominal pain was present at some period of the attack. Of these there were 222, or 44 per cent. Of these 222 cases there were 61 in which the pain was present only at the onset. This leaves 161 cases, or 32 per cent., with pain during the course.

In typhoid fever there are, of course, some patients with stupor or delirium in whom conditions usually causing pain may be present, but no complaint is made. With the employment of the bath treatment such are, however, not common and there are few such in this series.

These classes may now be considered in detail.

I. *No pain or tenderness at any period: 206 cases.*

It is of interest to note the occurrence in this group of conditions which at times apparently do cause pain. Of abdominal symptoms, marked distention was present in 27 cases, abdominal rigidity without distention in 6, diarrhœa in 20, distention and diarrhœa together in 2, and in 1 fœcal impaction. Hæmorrhage occurred in 9 of this class—in connection with which it may be noted that, among 36 cases of hæmorrhage, in 22 there was no pain with this complication, in the 13 other cases pain or tenderness occurred in connection with some other condition. Severe vomiting was present in 6 cases. Of thoracic conditions, pleurisy, pneumonia, and pericarditis were present in one each. Abscess of the liver occurred once and marked distention of the bladder six times. It will be noted that there was no instance of perforation. The general impression obtained on reviewing these cases is that they included many of a mild type. There were eight deaths among them—a low rate, but one must remember that none of the cases of perforation and few of the cases of hæmorrhage come in this division.

II. *Tenderness only: 72 cases.* This is a common symptom and, of course, was present in many of the third group. These records are based on the records of ordinary abdominal palpation and probably, if severe pressure were used, tenderness would be present to some degree in more cases. The situation of the tenderness when noted was as follows: General in 26, right iliac fossa in 11, over the lower abdomen in 9, umbilical region in 8, left iliac fossa in 4, epigastrium in 3, and 1 each in both iliac fossæ and hypogastrium. Of associated symptoms, distention was present in 13, diarrhœa in 10, marked muscular rigidity in 6, distention with diarrhœa, hæmorrhage, obstinate constipation, and distended bladder in one each. The statement made by Strümpell that tenderness is most marked with constipation does not seem to be supported by these cases. Constipation was the rule among this series.

III. *Occurrence of abdominal pain: 222 cases.* These may be divided into two groups, one with pain only at the onset, and the other with pain present during the course. The latter group of 161 cases can be divided up into several divisions, which it seems convenient to do in the consideration of the cause.

1. Pain due to conditions apart from any special lesions of the disease, including hysteria, lung conditions, bladder, abortion, labor, and menstruation.

2. Conditions of the gastro-intestinal tract apart from complications, including food, vomiting, constipation, and diarrhœa.

3. Abdominal conditions apart from the specific bowel lesions, including appendicitis, peritonitis (other than due to perforation), cholecystitis, liver abscess, painful spleen, phlebitis.

4. Specific intestinal complications, hæmorrhage, and perforation.

5. No discoverable cause.

Pain at onset. This was the case in 166 cases, in 61 of which the pain was only present at the beginning and not during the course of the disease. The severity of this symptom may lead to error in diagnosis. In cases associated with diarrhœa and without high fever the condition may be thought to be only an enteritis. If the abdominal symptoms are more severe and there are signs in the abdomen, such as localized tenderness, muscle spasm, etc., a diagnosis of appendicitis or peritonitis may be made. There were four cases of this series in which this error was made. Two were considered to be appendicitis from the severity of the pain and the local symptoms. In one of them, that of a patient admitted to the gynæcological service with marked abdominal pain, tenderness, muscle spasm, and leucocytosis, the abdomen was opened. In the two other patients a diagnosis of peritonitis had been made, one being sent in on the gynæcological side. During the same period two patients were admitted to the surgical side with a diagnosis of peritonitis, and immediate operation showed perforation of a typhoid ulcer.

Pain during the course: 161 cases. It may be said that in the majority of these cases complaint of pain was made by the patient.

1. With hysteria, lung conditions, bladder, abortion, labor, and menstruation.

(a) *Hysteria and nervous conditions.* Of pain due to this there were four instances, two in either sex. In one man severe pain was complained of and, on palpation of the abdomen, there was great tenderness. His respirations rose at once, on examination, to 56 to the minute and were sobbing in character. There were other suggestive neurotic features in the case, and little doubt was felt as to his condition. The other man showed symptoms which were more difficult to place. He complained of sudden intense abdominal pain with which he cried out so loudly as to disturb the ward. There was pain on palpation and there was rigidity of the abdominal muscles. Soon he became nauseated and vomited. He made so much outcry and was so emotional that suspicion was aroused. After these symptoms had been present for forty-eight hours they suddenly cleared up and he was quite comfortable. Later he had two similar attacks which were shorter, perhaps on account of the scant attention he received. The third case was in a woman who had taken some training in nursing. She complained suddenly in the night of severe pain in the right iliac fossa. On palpation, there was marked tenderness with rigidity of the muscles on the right side. She was rather neurotic, and we attributed her symptoms to this. Her knowledge of disease was enough to enable her to give many of the symptoms of appendicitis, which she said she thought she had. At the end of twenty-four hours all the symptoms disappeared. In the fourth case the pain came on after a pronounced nervous attack. The patient screamed with pain and the associated features

were marked. This condition is rarely likely to lead to a mistake in diagnosis. There are apt to be other suspicious symptoms. Still, as in the second case noted above, the recognition may be very difficult.

(b) *With pleurisy and pneumonia.* There were three instances of this, two with pleurisy and one with pneumonia. In one of the former, with a pleurisy in the left side, there was abdominal pain in the epigastrium and left hypochondrium. In the second instance a pleurisy—evidently diaphragmatic at first—was accompanied by severe pain, usually in the left hypochondrium, but also at times in the epigastrium. This continued for nearly three weeks at intervals, during which time empyema developed, which finally required operation. In the patient with pneumonia, which was in the lower right lobe, there was at first general abdominal pain, greater on the right side and accompanied by marked rigidity of the muscles on that side. Such an abdominal condition might easily lead to error were the lung complication not discovered. In all these cases it seemed probable that the diaphragmatic pleura was involved. They lay emphasis on the necessity of careful examination of the thorax in all doubtful cases, to exclude any pleural cause of pain.

(c) *Pain due to a distended bladder.* This caused severe pain in four instances. Distention of the bladder is common in typhoid fever, but it is rare for the patient to make any complaint. In all of these severe pain was complained of by the patient. The recognition of the enlarged bladder, followed by the passage of a catheter, brings relief at once. The possibility of this cause of pain should be kept in mind and excluded in obscure cases.

(d) *Pain with abortion or labor.* This occurred in three cases. In the later periods of pregnancy there would be little chance of error as to the cause of the pain. In the earlier months, when abortion most often occurs, before the uterus is much increased in size and when the fact of pregnancy may not have been recognized, a mistake might easily be made. In women its possibility should be kept in mind.

(e) *Pain with menstruation.* This must be rare, as menstruation usually does not occur during the course of typhoid fever. It only occurred in one instance among this series.

There was no instance of pain associated with degeneration of the abdominal muscles or with rupture of the recti abdominales.

2. Gastro-intestinal conditions apart from complications—food, vomiting, constipation, and diarrhœa.

(a) *With solid food.* In two instances there was pain following the taking of solid food, both during pyrexia, the food having been smuggled in by friends.

(b) *With vomiting.* In three cases associated with severe and protracted vomiting, apart from any complications, there was severe pain.

(c) *With constipation and fecal impaction.* Pain

apparently due to constipation was present in ten cases, in three of which there was obstinate impaction. In two instances the pain was specially associated with the administration of an enema. There were no special peculiarities associated with the pain. As constipation is the rule in the majority of the cases, it does not seem to be a very common cause of abdominal pain.

(d) *Pain with diarrhœa.* This occurred in sixteen cases. The pain was like that of colic and was rarely continuous. It was often present just before the bowels moved or during the stool. The absence of other symptoms usually serves to render the cause evident. In two of these cases, however, the symptoms suggested an acute abdominal complication. In one there was severe general pain, with marked rigidity of the muscles on the right side. The pain lasted for two days and cleared up with improvement in the condition of the bowels. In such obscure cases the importance of excluding other conditions before giving opium on account of the diarrhœa is evident. A severe complication might be masked by opium given for pain and diarrhœa.

3. Various abdominal conditions—appendicitis, peritonitis, cholecystitis, liver abscess, painful spleen, phlebitis.

(a) *Pain with appendicitis, peritonitis, and obstruction.* Any acute abdominal condition which causes pain may occur in the course of typhoid fever. Others than those noted may happen, as, for example, intussusception. There were two cases of pain with appendicitis, in neither apparently due to typhoid lesions. In one there was severe abdominal pain present from admission, but there was a sudden definite increase with the onset of the complication. The pain was severe, worse on pressure, and associated with an increasing leucocytosis. Operation showed acute appendicitis. There was one case due to peritonitis. The patient had shortly before undergone a pelvic operation for pus tubes. With infection probably from that source she had severe pain, vomiting, tenderness, and leucocytosis. At the operation some obstruction was found due to adhesions, and the pain may partly have been due to that. Obstruction was a cause of pain in three cases, all after operation, two for perforation and one for liver abscess. The pain in these was severe and paroxysmal, frequently making the patients cry out. In these cases usually only a diagnosis of some acute abdominal complication can be made.

(b) *With cholecystitis.* This occurred in four cases, two of which were operated on. In the other two patients, the seat of pain, tenderness, local muscle spasm, with jaundice in one and leucocytosis in the other, seemed to render the diagnosis fairly certain. All of these complained of fairly severe pain in the upper right quadrant of the abdomen. With this there were great tenderness and muscle spasm. The situation of the pain, with the associated symptoms, would seem likely to prevent error in these cases.

(c) *With liver abscess.* Pain due to this occurred

once. In another case there was no pain whatever. The pain was in the upper right quadrant and was severe and paroxysmal, at times making the patient cry out. It was made much worse by pressure over the right costal margin. There was nothing in its character to distinguish it from that of cholecystitis.

(d) *With a tender spleen.* This was found in ten cases, and was usually most marked on palpation. In three instances at the time of the presence of the pain the spleen was not palpable, though felt later. In none did the spleen seem unusually enlarged. In only one case was a friction rub made out over the spleen. This pain is rarely likely to lead to any doubt as to its origin. Its situation and the increase on palpation usually render it clear.

(e) *With phlebitis.* This was the cause of severe abdominal pain in four instances. When it is stated that in two of these laparotomy was done, its significance will be appreciated and the possibility of the symptoms simulating those of perforation. In these two cases the pain came on suddenly and was very severe; there were marked abdominal symptoms, leucocytosis, and in one vomiting. At the operation no perforation or peritonitis was found, but thrombosis of the internal iliac veins. In the third case the pain came on suddenly after an enema; there were marked tenderness, hiccup, and leucocytosis. The presence of some tenderness in the left femoral region for two days before suggested thrombosis, although nothing was to be felt there. In the fourth case, with much the same symptoms, there had been some previous tenderness in the leg. An autopsy in one case showed thrombosis of the left iliac vein, and subsequent œdema of the leg supported the diagnosis in the other cases. The sudden onset and the character of the pain are very like those of perforation. The marked tenderness, leucocytosis, and perhaps vomiting may all tend to support this view. Careful examination of the vessels in the legs and over Poupart's ligament should be made, and the presence of signs there would be an important point in the diagnosis.

4. Pain with hæmorrhage and perforation.

(a) *With hæmorrhage.* This was associated with pain in 14 cases, among a total of 36 cases of hæmorrhage, so that it appears to be by no means a constant symptom. In nearly all these cases the pain was severe and was complained of by the patient. In some it came on in paroxysms, in others it was more continuous. Its character may suggest perforation, the possibility of which has to be kept in mind. The two complications occurred together in two cases of this series, and in both the mistake was made at first of attributing all the symptoms to the hæmorrhage. Of the thirty cases of perforation since the opening of the hospital to date, April 1, 1901, six have been accompanied by hæmorrhage. In a doubtful case, with pain, the blood examination may show a marked drop in hæmoglobin and red corpuscles before any blood appears externally. This was a valuable diag-

nostic point in one of our recent cases. In one case, with a sudden onset of severe pain, vomiting, abdominal tenderness, and increased pulse rate, the suspicion of perforation was so strong that an exploratory operation was done with negative findings. The occurrence of leucocytosis in some cases of hæmorrhage also adds to the difficulty of diagnosis. The possibility of hæmorrhage and perforation occurring together puts emphasis on the importance of making a thorough examination and excluding, if possible, the presence of perforation in all cases of hæmorrhage—especially those with pain—before giving opium, with its masking effect on the symptoms. There were three of these cases that showed the presence of pain for some days before the hæmorrhage. This was also noted in some of the cases of perforation. Whether this was an accidental coincidence or not is difficult to say. The pain did not continue after the hæmorrhage.

(b) *With perforation.* This occurred in 13 in the series of 500 cases, and in all abdominal pain was present. Pain is probably the most constant and valuable symptom of this complication and demands careful study. In some patients with marked toxæmia no complaint will be made, and the perforation may only be discovered at the autopsy. Of the patients in this series every one made complaint of pain, and in all the pain seemed severe. The mode of onset of the pain is of interest. These cases may be put into two groups as regards this: (1) With a definite sudden onset, of which there were ten, and (2) those cases with pain for some days before the perforation, of which there were three. In the first of these groups the onset was strikingly sudden in several of the cases. The patients had previously been quiet and comfortable, and suddenly were seized with severe pain, which in four was severe enough to make them cry out. In four it was accompanied by vomiting. In three the pain at the onset was referred to the penis. If this mode of sudden onset occurs, it is very suggestive of perforation. It is important that one should, if possible, see the patient at once, for in a few minutes the severity of the pain may be over and the patient comparatively comfortable. The nurses should be instructed to call the house officer at once when any complaint of abdominal pain is made. The gravity of the case may be realized by the sight of the patient at the onset as it may not be later. This has been impressed on us by some of our recent cases. A sudden onset of pain demands the most careful examination of the patient and careful noting of every symptom and all the conditions, as advised by Dr. Osler. An endeavor should be made to exclude all other possible causes of the pain.

The pain did not remain constantly severe in any instance, but was paroxysmal in character, the patient in the interval being perhaps almost completely free from any pain. Should the patient be seen in one of these intervals—as by a consultant—a very different picture may be presented than a short time previously. In such cases perhaps a couple of hours should be spent in frequent

observation of the case. It is only by doing this that it may be possible to properly estimate the amount and character of the pain. The importance of this careful and constant watching has been brought home to us in some of our recent cases. In one patient the recurring paroxysms of severe pain, with some increase in the respiration rate, were the only symptoms of perforation present for eight hours. Then suddenly tenderness and muscle spasm appeared. Looking back over these cases, the remarkably sudden onset, like a bolt out of the blue, has been a very decided feature. But the second group have to be kept in mind, namely, those in which the patients have had pain for some days before the perforation. In these there is no sudden onset with pain, nor may there be any increase in that previously present. There were three of these among this series. Next to the cases without any pain, they are the most difficult to recognize. When a typhoid patient complains of pain for days and shows abdominal symptoms with perhaps a leucocytosis, the onset of perforation is not likely to make much change in the picture. It may only be the resulting general peritonitis that is made out. In these three patients pain was present for five, nine, and ten days before the perforation. All had abdominal features, tenderness and rigidity or muscle spasm, and in two leucocytosis was present. In one of these patients a sudden severe exacerbation of the pain suggested perforation, in the second the onset of vomiting suggested the general peritonitis which was found at the operation, and in the third the perforation was not recognized. The cause of this preperforative pain is difficult to give. One might suggest a local peritonitis, but an operation in two and section in one of these did not support this view. It may merely have been a coincidence, as there is a group of cases to be described later in which pain, leucocytosis, and abdominal symptoms were present for days, without any subsequent perforation.

5. Pain without any discoverable cause.

Under this heading come 70 cases, a surprisingly large number. In almost all the pain was first complained of by the patient. It was, as a rule, not very severe and of short duration. In only eight of the series was pain present for some days, varying from four to two weeks. In three instances the complaint of pain was made in the tubs. It did not persist after the patient was put back into bed. In two it was associated with nausea and in three with vomiting. In all these cases careful examination was made for some cause of pain, but none could be found.

While the majority of these cases showed no special features, yet there is one group to which attention should be directed, as the cases simulate perforation to some extent. The unusual features, in addition to the occurrence of pain, were the presence of leucocytosis and local abdominal symptoms. There were 14 of these cases. Leucocytosis in typhoid fever speaks for a complication, and hence its importance in these cases. Curiously enough,

the number of leucocytes showed little variation, the lowest being 10,000 and the highest 17,000 to the cubic millimetre. The average for the 14 cases was 12,700 to the cubic millimetre. The leucocytosis usually developed suddenly, and in some instances lasted for some days. In addition, most of the cases showed suspicious abdominal symptoms and were under both medical and surgical observation. Two patients were operated on. In one the sudden onset of severe pain, rigidity of the abdominal muscles, tenderness, leucocytosis, and diminishing liver dulness seemed to demand an exploration. On opening the abdominal cavity, a slight amount of free fluid was found, and there were numerous swollen Peyer's patches, the surface over one having a red, "angry" appearance. The patient made a good recovery. In the second case there were much the same symptoms, but nothing was found at the operation. The patient died four days later. In another patient there was sudden severe cramp-like pain in the abdomen, with tenderness and a leucocytosis of 15,000 to the cubic millimetre. With these symptoms the temperature fell over four degrees in eight hours. His general condition was good, but could more worrying symptoms be imagined? The subsequent course showed that the sudden drop in temperature was a termination by *crisis*, and the other features cleared up without any cause being found. Without giving any more of these cases in detail, it may be said that they all were the cause of much anxiety. Two of the patients died, both apparently of intense toxæmia, and at the autopsy no cause for the pain could be found, unless it was due to enlarged mesenteric glands. Abdominal pain has been described as occurring with suppurating mesenteric glands, but whether the ordinarily enlarged glands of typhoid fever can give rise to pain is a question.

What is the cause of the leucocytosis in these cases? There seemed to be a connection, at any rate in some of them, between the leucocytosis and the pain. They came and went together. Perhaps the first possibility that suggests is the occurrence of phlebitis in some of the abdominal or pelvic veins, which might be of small extent. This was kept in mind, but no evidence of its presence was discovered. Careful examination was made to exclude it with the various other causes discussed before. A local peritonitis may be thought of, but what evidence have we that such was present? Neither the patients operated on nor those coming to autopsy showed any signs of it, unless the red, somewhat granular serous surface over an inflamed Peyer's patch could be considered such. Besides, local peritonitis does not seem to occur very often in typhoid fever. This group of cases seems to be worthy of consideration in the general question of the diagnosis of perforation. In the majority of these cases the absence of pronounced local abdominal symptoms, such as tenderness, rigidity, muscle spasm, etc., was of value in the diagnosis. Under examination, there would be little or no change in the local abdominal con-

ditions in most of them. Where these were present, as noted in two cases, an exploration seemed justified.

As to the cause of abdominal pain generally in typhoid fever, little can be said that is satisfactory. In certain of the complications an explanation is evident, but why, for example, should some patients have severe pain with hæmorrhage? Many of the conditions are common to all patients with the disease. Is it, then, largely due to individual peculiarities? The common intestinal conditions, such as distention, constipation, diarrhœa, etc., seem to be a cause in comparatively few cases. A local peritonitis, which is often advanced as an explanation, must be a rare cause, judging from operation and autopsy experience. Is there pain associated with an inflamed serous surface over an inflamed Peyer's patch—which, perhaps, some might term a local peritonitis? In some instances apparently there is, as was found in one of our cases. The patient had complained of pain for some days, with tenderness on palpation, but no other symptoms of importance. With a sudden increase in the pain, muscle spasm, and leucocytosis, some acute abdominal complication seemed probable, and an exploration was done by Dr. Mitchell. No general anæsthetic was given, the abdomen being opened under cocaine. His pain and tenderness were greatest just to the right of the navel. On opening the abdominal cavity, on the intestine just below this point was a large Peyer's patch, with the serosa much inflamed and having a somewhat granular look. The patient's eyes were covered so that he could not see. This loop of intestine was brought out of the abdominal cavity. With the handling of the intestine he made no complaint of pain, but even a gentle touch over this inflamed area made him cry out with pain, which he said was exactly like the pain which he had felt before the operation when pressure was made on the surface of the abdomen just to the right of the navel. An acute appendicitis was found. The appendix was removed and the patient made a good recovery. Yet in other cases, with exploration done under cocaine, the patient made no complaint when the serous surface over the ulcers was handled. Whether deep ulceration may be a cause of pain in some cases is difficult to say. It certainly is not constantly associated with pain, as patients who have been free from pain throughout have been found at the autopsy to have deep ulceration. It is possible that phlebitis may be present more frequently than we suppose. Perhaps lymphangitis may be a cause in some cases. Lennander (9), in a recent article, reports observations on the sensation of the peritonæum, made in patients operated on with cocaine anæsthesia. He considers the visceral peritonæum as being practically insensitive in contrast to the parietal peritonæum. However, in certain cases the visceral peritonæum is evidently very sensitive. While in some cases of abdominal pain in typhoid fever an explanation for the occurrence of pain is evident, yet in many there seems to be no satisfactory way of accounting for it.

SUMMARY.

From the study of these cases the following conclusions can be drawn:

1. About two fifths of the patients are free from pain or tenderness, rather less than one fifth have tenderness only, and pain is present at some time in about two fifths of the cases, but during the course only in about one third.

2. Pain due to some condition other than the specific bowel lesions was present in about 14 per cent. of all cases and in about two fifths of the patients having pain during the course.

3. Pain occurred with hæmorrhage or perforation in about 5 per cent. of all cases and in about 15 per cent. of the cases in which there was pain during the course.

4. Pain was most constantly present with perforation, when it was usually sudden in onset, severe in character, and paroxysmal in occurrence. The pain of perforation was most closely simulated by that occurring in some cases of hæmorrhage, that from phlebitis, and that of unknown origin.

5. In about two fifths of all cases with pain during the course no cause could be found. Should this occur with other abdominal symptoms the condition may much resemble perforation.

SPINAL ANÆSTHESIA BY CATAPHORESIS.

By J. LEONARD CORNING, M. D., LL. D.,
NEW YORK.

I HAVE been conducting some experiments this winter with a view to modification and possible improvement of the technique at present in vogue for inducing spinal anæsthesia. Urged to place on record the nature and significance of these observations, yet lacking both time and energy, just now, to indulge in a lengthy and more formal writing, I take the liberty briefly to set down the following points:

To make the anæsthetic penetrate the membranes without puncturing them, by Cataphoresis.—To this end

I invoked the services of a tube four inches long, terminating at one end in a small metal bulb, pierced to give passage to a tube of smaller calibre, upon passing the latter down through the larger tube. At the other (upper) end of the larger tube is a binding-post for securing the conducting cord (positive pole) of a galvanic battery.

The smaller tube, which projects an inch and a quarter beyond the upper end of the larger tube, is provided with the socket requisite to attach it to a hypodermic syringe (glass). A diminutive metal collar, sliding along the smaller tube between the socket and the upper end of the larger tube, may be kept in place at any point by the aid of a small set-screw. By this device it is possible accurately to regulate the distance to which the small tube shall be thrust beyond the bulbous end of the larger tube (about half a centimetre). The lower end of the smaller tube has no bevel whatever, and is slightly rounded at the edges. The larger (outer) tube is insulated throughout its entire length, save at the bulb, which is bare.

From the foregoing description it is not difficult to divine my intention. Briefly, I proposed to introduce the larger (insulated) tube between the spinous processes of the third and fourth lumbar vertebræ till the metal bulb was stopped by the ligamentum subflavum, then to thrust forward the inner tube sufficiently to pierce the ligament, yet leave the dura and arachnoid unscathed, a thing very easily done, as these membranes, bolstered only by the yielding cerebrospinal fluid, would inevitably give before the rounded end of the small tube, which could at most indent, but never pierce them.

Once having pierced the ligamentum subflavum, I would attach the syringe to the small tube, and inject the anæsthetic upon the dura. This done, I would unscrew the syringe, withdraw the smaller tube, and, securing the positive conducting cord of a galvanic battery to the binding-post of the larger tube—the negative sponge of the battery being already over the abdomen—cause the current to pass. The cataphoretic action thus resulting would, I hoped, materially aid the passage of the anæsthetic through the membranes.

During the early part of last winter I had an opportunity of putting all this to the touch of proof in a man to whom it was thought inadvisable to give a general anæsthetic. I was requested by Dr. T. J. McLoughlin, who evinced a lively interest in what was proposed, to attempt to produce spinal anæsthesia in this patient, then lying at St. Francis's Hospital, Jersey City.

Without entering into collaterals, I will state briefly what I did. With a Graefe knife, I made an incision between the spinous processes of the fourth and fifth lumbar vertebræ, a little to the right of the ligamentum interspinosum, thrusting it down till the ligamentum subflavum was nearly reached. Into the incision thus made I thrust the outer (insulated) tube of the before-mentioned instrument* till its bulb came to rest upon the

ligamentum subflavum—was stopped by it in fact, precisely as intended. The inner tube was then thrust through the larger tube till, the ligamentum subflavum being pierced, the syringe could be screwed on and its piston withdrawn, whereby we convinced ourselves that the membranes had *not* been pierced. The syringe was then unscrewed, filled with a two-per-cent. solution of the hydrochloride of cocaine, and thereafter rescrewed to the tube. Fifteen minims of the solution were then injected, that amount being deposited between the dura and the vertebral canal. The inner tube was then withdrawn (within the outer one), and the binding-post of the outer tube attached by a long conducting cord to the positive pole of a galvanic battery provided with a milliampère-meter graduated in tenths of a milliampère.†

A large sponge, attached to the negative pole of the battery by a long conducting cord, was then applied to the abdomen, and the current turned on till the milliampère-meter showed three tenths of a milliampère. The current was allowed to do its work in this way for upward of twenty minutes before the precursory paræsthesiæ began to be felt. There was then a long time of waiting—perhaps half an hour—before any true anæsthesia appeared, and this was too irregularly distributed to permit of operating.

Not wishing to detain the surgeons and the large number of other medical gentlemen present, I suggested applying the ether cap. This was done, but scarcely were the preliminary steps of the operation—an osteotomy of the foot—taken, when the house surgeon drew my attention to the facts that he had left off giving the ether, and that the patient, now entirely conscious, was suffering no pain whatever. From now on, there was no giving of ether whatever, the subject conversing with those about him quite contentedly and without the least sign of discomfort, although cutting, chiseling, sawing, and suturing were indulged in, according to the technical demands of the occasion. After the removal of the subject from the operating-room to the surgical ward, the anæsthesia of the legs persisted for considerably more than an hour.

Physiologically, then, the undertaking was a success; practically, I do not think it was—not because of the few whiffs of ether given at first, but because of the very long time necessary to induce the anæsthesia and the rather formidable paraphernalia required. My friends, however, have thought the observation of scientific interest, and, yielding to their amicable persuasions, I have taken the liberty of recording it, trusting that others may improve upon it or be saved the trouble of going over the same ground.

In conclusion, I desire to express my sinceré acknowledgment and appreciation of the zeal shown in these efforts by Dr. McLoughlin and the entire staff of St. Francis's Hospital.

THE PATHOLOGY AND BACTERIOLOGY OF URETERO-INTESTINAL ANASTOMOSIS.*

By F. ROBERT ZEIT, M. D.,

CHICAGO,

PROFESSOR OF CLINICAL PATHOLOGY, BACTERIOLOGY, AND HYGIENE
IN THE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL
AND POST-GRADUATE MEDICAL SCHOOL.

URETERO-INTESTINAL anastomosis, or the implantation of both ureters into the rectum, would be a very acceptable procedure to the surgeon in all cases of malignant disease of the bladder, or its neighboring organs,

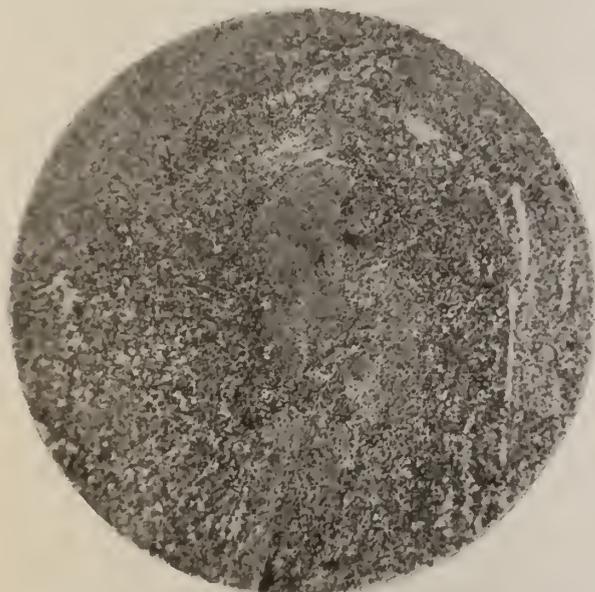

FIG. 1.—Specimen from medullary pyramid. Central necrotic area with colon bacilli in collecting tubules, surrounded by a dense zone of leucocytic infiltration.

in which the bladder must be removed. Maydl's operation, by which the vesical trigonum with its natural ureteral orifices is implanted into the sigmoid flexure, is only applicable to cases of exstrophy of the bladder. Surgeons have for years experimented to produce uretero-intestinal anastomosis with a view of preventing the bad effects attendant upon the lack of the natural orifices, which allows an entrance of the bacteria of the intestine into the ureters and resulting ascending renal infection and pyelonephritis.

The cases upon which this report is based include the various operations recommended and done by Dr. Franklin H. Martin and Dr. Reuben Peterson on 141 dogs, with a view of devising an operation which should do away with the attendant dangers of such operations, and an experimental study of the pathology and bacteriology of the same. I am indebted to the above-named gentlemen for assigning the latter part of this investigation to me.

After more than two years of faithful work in this direction, I am forced to the conviction that, no matter

*Read before a joint meeting of the Chicago Pathological Society and the Society of Internal Medicine, December 10, 1900.

what operation is done, the pathology of ureteral implantation into the rectum is the pathology of pyelonephritis and its sequelæ, if it is permissible to judge from operative results upon dogs. It does not appear from the literature that the conditions for recovery in the human individual are much more favorable with better care and control of the patient and better hygienic surroundings.

The high mortality of ureteral implantation into the rectum, 84 per cent., during the first two days even, is a serious objection, but a more important one yet is the fact that dogs which had recovered from the operation and the resulting pyelonephritis, and were to all appearances in perfect health and vigor again, *all* had granular contracted kidneys. Without exception they all had pyelonephritis shortly after the operation. When killed, from five to thirteen months later, these "cured dogs" were found to have small, hard, contracted kidneys due to induration and cicatrization of the diseased areas following pyelonephritis.

History.

The extensive literature on ureteral implantation has been collected from original sources in a most thorough manner by Dr. Reuben Peterson (1) and Dr. Franklin H. Martin (2).

Ureteral Implantation into the Rectum in Dogs.—Of sixty unilateral and sixty-eight bilateral implantations on dogs reported in the literature, with a mortality of 61 per cent. for the unilateral and 85 per cent. for the bilateral operation, the cause of death is given as—peritonitis in fifty-one, stenosis of the ureteral orifice and hydronephrosis in thirteen, pyelonephritis in twenty-nine, and uræmia in six. Unfortunately, very few of

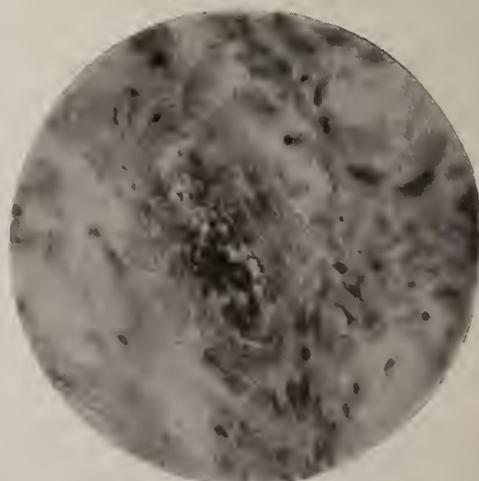

FIG. 2.—Colon bacilli in the blood-vessels.

the experimenters have deemed it necessary to report the pathological or bacteriological findings.

Of the dogs which recovered, not one has been proved to have had healthy kidneys when killed.

Bardenheur (3), Navaro (4), Rosciszewski (5), Giordano (6), Weller Van Hook (7), and Duval and Tesson (8) report that the dogs which recovered from

the operation had pyelonephritis, hydronephrosis with hydro-ureter, and stenosis of the ureteral orifice. Kalabin (9) reports one dog with unilateral implantation of the ureter into the rectum as having interstitial nephritis of the corresponding kidney.

Morestin (10), after ten bilateral and fourteen unilateral implantations, with fatal results in all, concludes that the primary mortality in man should be less than in animals, because of the larger size of the ureters and the possibility of better asepsis.

Giordano (6), after having done sixteen operations, concludes that without obstruction of the ureters no infection of the kidney should occur.

Weller Van Hook (7) did ten unilateral and six bilateral operations. His cases were thoroughly examined pathologically and bacteriologically. All the dogs which recovered from the operation (7) had pyelo-

Smith (14) reports a bilateral implantation with death after fourteen months of pyelonephritis.

Duplay (15) reports two fatal cases of bilateral implantation. Pyelonephritis took place, with death a few months after operation.

Casati (16) had a death from pyelonephritis in thirty-five days after a unilateral operation.

Tuffier (17), Fritsch (18), Krause (19), and Wood (20) report similar cases.

Peterson (1) collected thirty-one cases from the literature (seventeen bilateral and fourteen unilateral). Only nine of the patients recovered (five from the bilateral and four from the unilateral operation), a mortality in man of seventy-one per cent.

If we exclude the four cases of unilateral implantation because the corresponding kidney may have been diseased or inactive, and the patient lived upon his

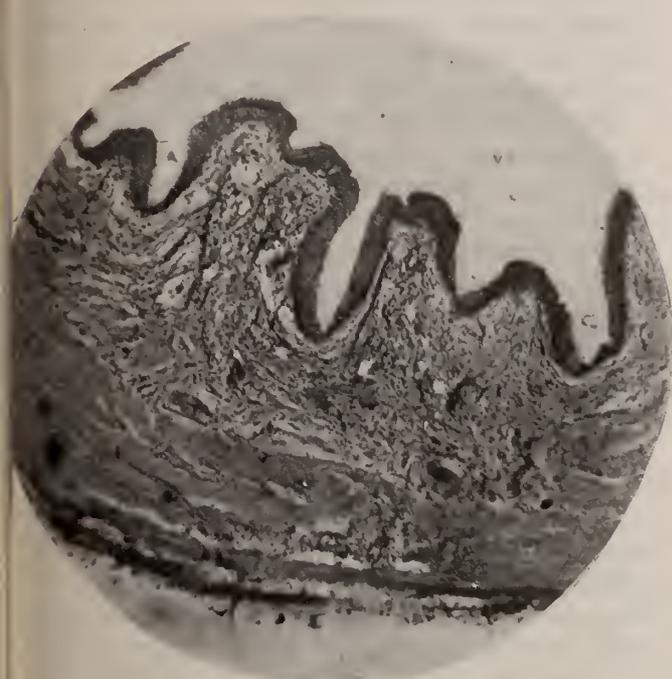

FIG. 3.—Ureter implanted into the rectum. The ureter is comparatively healthy, in strong contrast to the necrotic papillae and severe pyelonephritis of the same kidney.

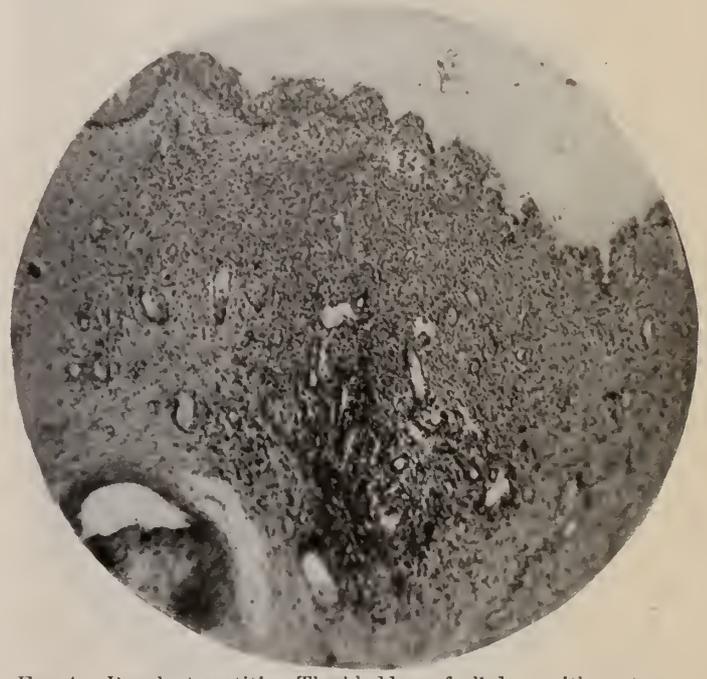

FIG. 4.—Purulent cystitis. The bladders of all dogs with ureters in the rectum are infected by way of the urethra. Small-cell infiltration of the mucosa. Desquamation of covering epithelium.

nephritis. He concludes that implantation of one or both ureters into the rectum is an unjustifiable operation under all circumstances.

Chaput (11), after a series of experiments on dogs with fatal results in all, concludes that experiments on dogs are of but little value as to man, because the bacterial contents of the dog's intestine are more virulent. He fails to bring forward any proof of this assertion.

Frank (12) does not expect any better results in man than in animal experiments.

Ureteral Implantation into the Rectum in Man.—Ureteral implantation into the rectum in the human being was first employed by Simon (13) in 1851. In this case the patient died of pyelonephritis one year after a bilateral operation.

other kidney, there are only five recoveries reported, as follows:

Krause (19), three months and a half.

Peters (21), ten months.

Chalot (22), twelve months.

Beck (23), twenty months. (In this case the patient died in December, 1900, of pyelonephritis.)

Fowler (24), four years and a half.

The first four can hardly be said yet to be fully recovered, as we shall see presently. This leaves only Fowler's case, in which he did a bilateral ureterorectal anastomosis for exstrophy of the bladder in a boy of six years. This patient is still alive, four years and a half after the operation.

Martin (2) concludes that animal experiments will

never solve the problem of urcterorectal anastomosis because:

(a) The care and hygienic surroundings of the animal cannot be so complete as in man;

(b) Gravity, exerted upon the urine of the upright human patient, is lacking in the horizontal animal, thus increasing the danger of infection;

(c) The rectum of the human patient can be kept clean;

(d) Ureteral catheters can drain the ureters for several days after the operation and thus protect the mouths of the ureters from infection when resistance of the tissues is at its lowest;

(e) Compensatory resistance to infection is higher in man.

He thinks the evidence furnished by recorded cases

FIG. 5.—Showing the invasion of uriferous tubules by colon bacilli during the first forty-eight hours after implantation of the ureters into the rectum. The dark portions are bacterial casts in convoluted tubules.

of this operation in the human being "has in it not a little which will stagger the pure theorists."

I have carefully examined his tabulated list of seventy-four cases collected from the literature which he offers as "furnishing the evidence with which to refute the theory of ascending infection in man," and fail to find any material difference in the results from those furnished by his own experiments and those of Peterson on animals. On the contrary, I have been amazed to find in a study of the literature on the subject during recent months how closely the results of my work on Martin's and Peterson's dogs agreed with those in the human being.

We must naturally exclude from Martin's list of the literature of seventy-four cases in the human being all

those in which a Maydl operation was done, to make fair comparisons between animal experiments and the results of his operations on dogs. Only cases of uretero-intestinal anastomosis should be considered.

Chaput's (11) case, in which the patient is well eight years after implantation of but one ureter, furnishes no proof. The patient is living by his other kidney, as several of our dogs did in which a unilateral implantation was done.

Peters's (21) and Krause's (19) cases, in which the patients were well, respectively, five weeks and three months after the operation, can hardly be considered yet as recovered.

Chalot (22) and Kryuski (25) report one case in which the patient was well after one year.

Bergentheuer (26) reports one patient well after a year and a half.

It is very probable that these patients have the same contracted kidneys which our "cured" dogs showed when killed, after having apparently perfectly recovered from the operation done—300 to 405 days before.

This leaves only von Eiselberg's (45) two cases, in which the patients were well after three and four years, and Fowler's (24) patient, well four years and a half after the operation, whose case has already been quoted.

Martin's operative results on the human being, which he reported in the same article (2), also agree with those of his animal experiments. With all his technical skill, acquired by such a large experience in uretero-intestinal anastomosis in animals, his results in the human being are not better than those obtained in animals.

It would seem from all this that we cannot expect any better results in man than in animal experiments.

Implantation of the Trigonum—Maydl (27), for Exstrophy of the Bladder.—To prevent renal infection, Maydl, in 1894, recommended as an operation for exstrophy of the bladder the implantation of the vesical trigonum and its ureteral orifices into the sigmoid flexure. The thirty-six cases collected by Peterson from the literature showed a primary mortality in this operation of nineteen per cent. The subsequent results are as follows: After one year, nineteen living; after two years, ten living; after three years, seven living; after four years, four living; after six years, one living; after seven years, one living.

Pathological and Bacteriological Findings.—Individual reports of some of the findings have already been published, together with descriptions of operations performed by Martin (43 and 44) and Peterson (1). A summarization of them represents a description of the various stages of pyelonephritis and its sequelæ. All the variations of this form of suppurative nephritis have been seen in the dogs operated on—from the earliest beginning of this ascending infection, a few days after the operation, up to the healed condition with induration and cicatrization, the granular, contracted kidneys which are found in all dogs that have recovered from the pri-

mary results of their pyelonephritis. The majority of our cases plainly showed that infection could only have taken place by way of the ureters, the pelvis of the kidney, and the uriniferous tubules, and that the pyelonephritis was caused by the *Bacillus coli communis*.

The earliest changes are found in the papillæ. Extensive necrosis is seen here very early. Soon after, yellowish flame-like rays extend into the pyramids, and finally small abscesses in the form of yellow elevated granules of the size of a pin head; some with and others without a narrow red zone are seen upon the surface of the cortex. Upon section, these can be seen to extend into the medulla. The kidney is enlarged and soft. Sometimes only one or more papillæ and medullary pyramids are involved, and their corresponding area of cortex. If the whole kidney is involved, multiple secondary pyæmic abscesses and endocarditis lead to the death of the animal. Colon bacilli are found in the lumen of the uriniferous tubules, surrounded by a necrotic and fatty zone, outside of which is a zone of leucocytic infiltration (Fig. 1). The interstitial tissues and lumen of the tubules contain enormous numbers of polymorphonuclear leucocytes and extravasations of blood, so severe at times that the structure of the kidney becomes obliterated. In the cortex, fatty degeneration and necrosis of the lining epithelium of the convoluted tubules are found in the neighborhood of the affected regions.

Most of the dogs died of peritonitis due to leakage of urine, or general sepsis and pyelonephritis, during the first ten days. Dogs living a longer time died of pyelonephritis, pyelonephrosis, and pyæmia, or recovered from the pyelonephritis with contracted kidneys. It was not always easy to determine what form of suppurative nephritis was present. A number of the kidney specimens looked more like embolic suppurative nephritis and infection of hæmatogenous origin. Pyæmia and endocarditis were found in some of these cases, and it became questionable whether they had caused an embolic suppurative descending nephritis, or whether an ascending infection or pyelonephritis had caused the pyæmia. It is possible that in some of the cases a blood infection may have been ingrafted secondarily upon an already existing pyelonephritis, because I found colon bacilli in the blood-vessels of some of the sections (Figs. 2 and 3).

Orth (28) describes such cases with many small abscesses, distributed over the whole surface of the organ, as having been caused by the entrance of colon bacilli into the arteries, which then produce infectious capillary emboli in the cortex. Aschoff and Gaylord (29) also state that, when large abscesses have formed, the bacteria, having caused the ascending infection, may enter the blood-vessels of the kidney or enter the general circulation by the lymph-vessels, and thus add a descending to the ascending suppurative nephritis. The distinction is usually made that cocci cause the descending embolic suppurative nephritis, and bacilli (coli and

proteus) the ascending infection, or pyelonephritis, and that in the descending type the bacteria of the small cortical abscesses are in the capillaries of the glomeruli, whereas in the ascending infection they are in the convoluted tubules, having passed up into the cortex from the collecting tubules.

I cannot pass this without a brief discussion of the subject of the *excretion of bacteria by the kidney*. It would seem from our experiments, in which many cases with blood infections occurred, that we should have seen more of the descending infection, or embolic suppurative nephritis; but such was not the case. Several dogs in which only one ureter had been implanted into the rectum died of the pyelonephritis and pyæmia, but had only slight or no parenchymatous changes with colon bacilli in the other kidney and in the blood. There can be but one explanation of this observation: *Bacteria in the blood are excreted by the kidneys and may pass through normal glomeruli without necessarily producing any anatomical lesions.*

With regard to the excretion of bacteria by the kidneys, two essentially different views were held until re-

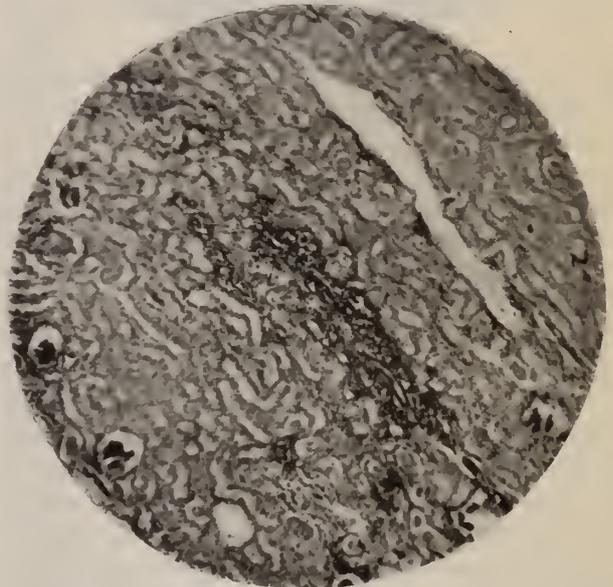

FIG. 6.—Beginning ascending infection within forty-eight hours after implantation of the ureters into the rectum. Hyperæmia, marked leucocytic infiltration, and some cloudy swelling.

cently. One is that anatomical lesions must be present in the kidneys to allow a passage of bacteria from the blood into the urine; the other, that the kidney furnishes a perfect physiological filter for all foreign elements of the blood. The first opinion found its greatest defender in Wyssokowitsch (30), who found staphylococci in the urine six hours and three quarters after intravenous injection, anthrax bacilli in twenty hours, and streptococci in forty-eight hours, always accompanied by anatomical lesions and rhæxis. He found weighty defenders of his views in his teacher, Flügge, and in Birch-Hirschfeld. Extensive experiments by Boccardi (31), Pernice and Scagliosi (32), and Konja-

jeff (33) appeared to support Wyssokowitsch's (30) opinion.

With regard to the second view, which is the generally accepted one to-day, that a physiological excretion of bacteria by the kidneys may take place without

FIG. 7.—Thrombosis of the portal vein in a dog that died, thirty days after ureteral implantation into the rectum, from pyelonephritis.

anatomical lesions, we find that as early as in 1870 Grawitz (34) found hyphomycetes spores in the urine for twenty-four hours without any red blood-corpuscles, after intravenous injection. No anatomical lesions were found.

Fütterer (35 and 36) described the glomerular excretion of tubercle bacilli in 1885, and typhoid bacilli in the urine in 1888. Fütterer concluded that tubercle bacilli were excreted by the normal kidney without causing tuberculosis of this organ, because his observations on a very extensive *post-mortem* material had shown him that in cases in which the other organs were densely covered with miliary tubercles, only few tubercles were found in the kidneys. He argues that in miliary tuberculosis, when the dissemination of the tubercle bacilli takes place, the kidneys must receive a good share of them, and certainly not less than other organs, and we could reasonably expect the kidney to be covered with as large a number of the miliary tubercles as we find in other organs. This can only be explained by the excretion of large numbers of tubercle bacilli by the glomeruli without causing any characteristic lesions.

Fütterer also instigated Schweizer's (37) experiments, which proved that living and dead foreign bodies might be excreted by healthy kidneys. Fine granules of carmin, barium, and stibium were found in the Malpighian bodies and convoluted tubules, and bacteria in the urine, three hours and a half after intravenous injection, without histological changes.

Ribbert (38) found staphylococci in the urine six

hours after injection, without pathological conditions in the kidney.

Baumgarten's (39) and Ernst Meyer's (40) experiments proved that tubercle bacilli could penetrate normal vessel walls (glomeruli) and enter the surrounding tissue.

Orth (28) states that bacteria may pass the glomeruli in pyæmia and produce bacterial casts in the uriniferous tubules, with the cortex and glomeruli remaining normal.

Biedl and Kraus (41) obtained cultures of the *Bacillus coli communis*, *Bacillus anthracis*, and *Staphylococcus aureus* in ten minutes after intravenous injection from the urine.

Fütterer's (42) experiments of last year, in which he obtained culture of *Bacillus prodigiosus* from the urine two and three minutes after intravenous injection, show that an excretion of bacteria takes place in such a short time that anatomical lesions, such as rupture of vessels and degenerative changes, can be excluded, and that a perfectly intact kidney may excrete bacteria by physiological function without anatomical lesions.

Fütterer and I recently undertook some experiments on dogs which go to prove the correctness of this position. Dogs with one ureter tied were injected, by way of the external jugular vein, with 2 cubic centimetres of a twenty-four-hour virulent culture of *Bacillus coli communis* in bouillon, and invariably were found to have pyelonephritis of the ligated side when killed, whereas the other kidney remained normal. Control animals had colon bacilli in the bladder for a few days,

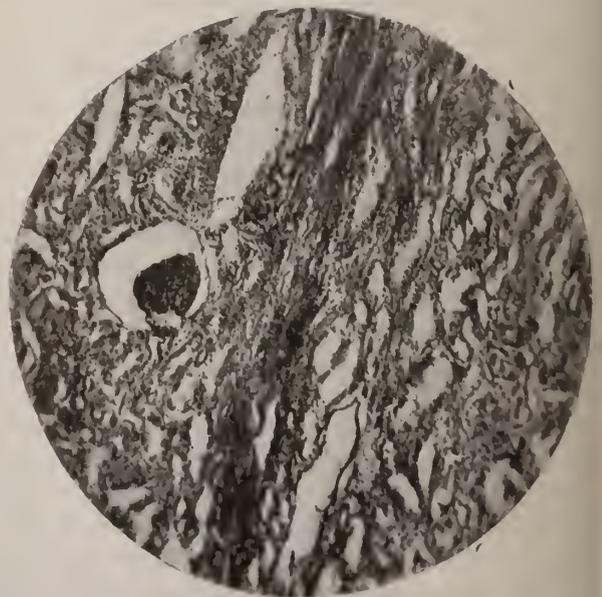

FIG. 8.—Interstitial small-cell infiltration. Dilated uriniferous tubules and capsules. Partly denuded epithelium.

but both kidneys were found perfectly normal when the animals were killed.

The results following the various operations performed are so uniform that I abstain from describing

the operation done. The ureters remain almost normal, although distended at times, and show very little or no leucocytic infiltration, no matter how extensive a pyelitis or pyelonephritis may be present.

After a search of the literature, I believe that Orth's (28) explanation of this phenomenon is the most feasible one. The motility of colon bacilli is not such that we might expect them to wander up the ureter. They simply rise to the highest level of the stagnant urine, due to more or less stenosis at the opening into the bowel, and thus enter the pelvis of the kidney and multiply there and in the collecting tubules.

Purulent Cystitis.—The bladder was always found to be infected by way of the urethra. In all cases in which the bladder had not been removed it was found to contain a purulent fluid teeming with bacteria, mostly *Staphylococcus albus* and *Bacillus coli communis*.

Sections show small-cell infiltration of the mucosa and submucosa, with desquamation of the covering epithelium. Peterson thought this effect was produced by not emptying the bladder of urine at the time of operation. I found, however, the same condition present in all the following cases, in which I took the precaution to squeeze out the bladder thoroughly before closing up the abdomen.

The examination of the dogs operated on includes:

1. Anatomical diagnosis.
2. Cultures from (a) cortex of kidneys;
(b) pelvis of kidneys;
(c) ureters;
(d) bladder;
(e) spleen;
(f) liver;
(g) heart-blood.

3. Direct cover-glass smear preparations from the same organs.

4. Sections of (a) kidneys;
(b) ureters;
(c) bladder;
(d) spleen;
(e) liver;

hardened in alcohol, imbedded in paraffin, and examined for (a) bacteria in tissues;

(b) histopathology.

5. Intraperitoneal inoculation of guinea-pigs with pure cultures of *Bacillus coli communis* obtained by plating out from kidney cortex in eight cases. All the animals died in from twelve to seventy-two hours.

Five dogs which had apparently recovered from the operation were chloroformed and cultures taken, as well as cover-glass smears, from the organs while the animals were alive. Sections of the various organs were placed at the temperature of life in absolute alcohol. This should exclude any possible questions of bacterial invasion of organs soon after death. These five animals were killed in from two to forty days after the opera-

tion, in from one to ninety days, in from one to 210 days, and in from one to 405 days, and all showed recent or old pyelonephritis, as will be seen from the report following.

(To be concluded.)

THE USE OF THE SUPRARENAL CAPSULE IN DISEASES OF THE HEART.

(Second Paper, with a Report of Cases.)

BY SAMUEL FLOERSHEIM, M. D.,

NEW YORK.

THE suprarenal substance is an ideal heart stimulant. No other drug can compare with it for rapidity of action, strength, efficiency, and safety combined.

My results were obtained with three grains of the dried powdered gland, loosely packed in a gelatin capsule.

Preparations.—The dried and powdered gland of the sheep can be obtained commercially. It is efficient and keeps indefinitely. For convenience of administration the powder is placed in a gelatin capsule. Tablets are useless.

Dose.—Three grains of the powder produce an effect. But larger doses, one drachm or more, are not injurious.

Method of Administration.—The mode of administration is important. Three grains of the dried suprarenal powder, loosely packed in a gelatin capsule, are thoroughly chewed, dissolved in the mouth, and swallowed without water. When tightly packed capsules or the tablets are administered, the action is uncertain or less rapid. For children, I usually administer an emulsion by the mouth, which is efficient; three grains of the powder are mixed in a little water in a teaspoon.

It is unnecessary to administer a solution of the suprarenal extract hypodermically, even when the patient is unconscious, as its effects are produced immediately, in less than one minute, when a solution of the extract is dropped into the mouth and absorbed by the mucous membrane of the buccal cavity.

Rapidity of Action.—The action of the extract became apparent in less than five minutes in two hundred cases of heart and lung diseases observed. In some cases the effect was noted within fifteen seconds. The effect continued for from five minutes to three hours or longer.

In one case, Dr. W. H. Bates syringed a solution of the extract into the lacrymal sac, while Dr. G. E. C. Kelly observed its effect on the pulse. While the fluid was flowing down the nasal duct and into the nose, and before all the fluid had left the syringe (about ten minutes), a high-tension pulse was observed to become softer. This effect was noted in less than ten seconds.

The suprarenal extract acts more promptly than other heart remedies, its *maximum* effect being obtained within five minutes, which is a much more rapid action than can be obtained from any of the other known heart remedies.

It also acts better and much more rapidly when it is absorbed before it reaches the stomach, as the juices of the stomach may interfere with the action of the suprarenal.

Physiological Action.—The suprarenal substance is a powerful muscle stimulant. Oliver and Schäfer, Cleghorn, and others, find that the extract increases the tone of all muscular tissue. Cleghorn, in experimenting on the dog's heart, found that the extract acted on the isolated apex in which it was believed that no nerves existed. He also states that the strength of the contractions of the heart was doubled by the suprarenal extract which, he believes, acted directly on the heart muscle.

It is not poisonous and it has no cumulative effect like digitalis. It does not act upon the nervous system.

COMPARISON OF THE SUPRARENAL EXTRACT WITH SOME OTHER HEART REMEDIES.

The Suprarenal Extract is indicated in organic heart disease with a weak, fluttering, intermittent or irregular pulse. It is likewise indicated in cases with dilated peripheral blood vessels, and also when the blood vessels are contracted, in cases with apparently a high-tension pulse and in all the valvular lesions. The reason the suprarenal extract is valuable in many cases of organic heart disease is that it acts directly on the muscle. As before stated, the maximum effect of the extract is obtained within five minutes, which is a much more rapid action than can be obtained from any of the other heart remedies. The action is continued for from five minutes to three hours or longer. The cumulative effect, such as is seen with digitalis, was not observed in a single instance in two thousand cases of diseases of the eye, ear, and nose, reported by Dr. W. H. Bates, or in the two hundred cases of heart and lung diseases which have come under my observation. This is a valuable property of the suprarenal extract, and enables one, without fear of later consequences, to administer the amount necessary to attain the desired result. It is not poisonous. It has no contraindications.

Digitalis is indicated in organic heart disease with an irregular, weak, or intermittent pulse, with dilated peripheral blood vessels, in aortic stenosis, in mitral regurgitation, and in mitral stenosis. It is contraindicated in a high-tension pulse with contracted peripheral blood vessels, in a fatty heart, and in aortic regurgitation. It is also contraindicated where there is gastric disturbance.

The suprarenal extract is indicated in all these conditions. One must be careful in the administration of digitalis, as large doses have caused alarming symptoms. Long-continued administration may suddenly show signs of poisoning, without any increase in the dose, from the cumulative action of the drug. When too large doses of digitalis are taken, the contractions of the ventricles become irregular.

The suprarenal extract has none of these objections.

Strychnine is indicated in organic heart disease with

a weak and irregular pulse. It is a poison, and the dose must be carefully considered. Strychnine does not diminish a high-tension pulse. It is contraindicated in patients having increased motor nerve force and in epileptics. It acts on the nervous system.

The suprarenal substance produces the beneficial effects of strychnine without its disadvantages.

Nitroglycerin is indicated in organic heart disease with a high-tension pulse and contracted peripheral blood vessels, although it is not altogether contraindicated in a low-tension pulse with dilated peripheral arteries. In a low-tension pulse, nitroglycerin does not apparently raise the blood pressure. It is a powerful poison.

The suprarenal powder benefits the same class of cases more efficiently and more rapidly, and the suprarenal powder is not a poison.

Strophanthus is similar to digitalis, with less objectionable properties. It is not so rapid or so safe as the suprarenal extract.

When strychnine or nitroglycerin is administered internally, at least twenty minutes are required for either of them to show its effects. When digitalis or strophanthus is administered internally, either of them requires at least one hour or more before its effects are observed, while the maximum effects are not obtained for four hours or longer.

The suprarenal produces its effects as promptly when administered internally as the before-named drugs do when they are administered hypodermically.

Uses of the Suprarenal Powder.—When the pulse was found to be weak the suprarenal extract made it stronger in all the cases of organic heart disease observed—eighty-two in number. When the pulse was irregular in force and frequency, intermittent, too slow or too rapid, it usually became more like the normal after the administration of the powdered suprarenal.

In cases with a mitral regurgitant murmur, it was observed that the murmur became lessened in volume and intensity, while in a few cases it wholly disappeared after the administration of the suprarenal extract. Other murmurs were lessened, increased, or unaffected. A dilated heart was contracted. When the normal cardiac sounds were indistinct and muffled, they became louder and more easily distinguished after the administration of the extract. The suprarenal powder has also aided in the diagnosis of organic heart disease; when the heart was very weak and the normal heart sounds and murmurs were indistinct and muffled, and after the suprarenal extract had strengthened the heart, the normal heart sounds and the murmurs became easily distinguishable.

The suprarenal extract is a most powerful heart stimulant. The evidence of this is conclusive. For, after digitalis, strychnine, nitroglycerin, and alcohol had failed to benefit, the administration of the suprarenal powder was followed by immediate relief.

Bates has reported a decidedly beneficial action on the pulse of organic heart disease after the instillation of the suprarenal solution into the eye.

It is remarkable that so powerful a substance should have no objectionable properties, and, while it is exceedingly active in cases which *need* benefit, the remedy has apparently absolutely no effect on the normal heart or on the heart of organic disease when its action is *not* needed.

CASES OF ORGANIC HEART DISEASE, IN WHICH THE SUPRARENAL CAPSULE PRODUCED AN APPARENT EFFECT—EIGHTY-TWO IN NUMBER.

CASE I.—The patient, a man, aged sixty-six years, had a mitral regurgitant murmur, the heart acting very irregularly. There was no radial pulse; the heart beats were thirty-nine. After the administration of the suprarenal capsule, the heart's action became regular and the normal cardiac sounds became plainer. The pulse was 63 and had returned at the wrist.

Remarks.—The patient had been in a state of collapse, but recovered without any other treatment.

CASE II.—The patient, a man, aged thirty years, had mitral regurgitation and irregular action of the heart; the pulse was 90, hard, and very irregular. After the administration of the suprarenal capsule, the action of the heart became more regular; the pulse was 90, softer, and more regular.

CASE III.—The patient, a woman, aged fifty-three years, had mitral regurgitation and aortic stenosis, and the action of the heart was weak and irregular; the pulse was 96, very weak, and irregular. After the administration of the suprarenal capsule the mitral murmur became lessened in volume and more localized; the heart was markedly stimulated. The pulse was 91, regular, full, and strong.

Remarks.—The patient felt well after the administration of the drug.

CASE IV.—The patient, a woman, aged thirty-nine years, had mitral and aortic regurgitation; the mitral murmur was loud; the aortic murmur was soft; the heart was much hypertrophied. The pulse was 84 and of fair force; one or two beats dropped every twenty seconds. After the administration of the suprarenal capsule the action of the heart became nearly regular, and the mitral murmur became less audible. The pulse was 84, and more uniform in quality and rapidity; the drops disappeared.

CASE V.—The patient, a man, aged fifty-six years, had mitral and aortic regurgitation; the action of the heart was very irregular. The pulse was 82, irregular, and hard. After the administration of the suprarenal capsule the mitral murmur became lessened in volume and more localized; the aortic murmur became much lessened in volume, and softer; the action of the heart became less labored; the apex impulse became less diffused. The pulse was 80, softer, fuller, and more regular.

Remarks.—The patient had an attack of rheumatism.

CASE VI.—The patient, a woman, aged forty-three years, had a rough mitral regurgitant murmur; there was slight aortic regurgitation; the apex beat was at the seventh rib, one inch and a half to the right of the left nipple line; there was marked cardiac hypertrophy with ginning dilatation. The pulse was 96, irregular, and weak; there were many beats dropped. After the administration of the suprarenal capsule, the heart acted more

regularly; the rough mitral murmur became smoother, lessened in volume, and more localized. The pulse was 88, nearly regular, full, and strong; all the intermittence disappeared.

CASE VII.—The patient, a man, aged thirty-nine years, had slight aortic and mitral regurgitation (Flint murmur); the apex beat was at the seventh rib, midway between the median line of the body and the left nipple line; the heart's action was irregular. The pulse was 109, irregular in force and frequency, and weak. After the administration of the suprarenal capsule, the action of the heart became regular and increased in force; the forcible apex beats became lessened in force; the aortic regurgitant murmur became almost inaudible; the mitral murmur was not heard. The pulse was 106, of good quality, and regular in force and frequency.

Remarks.—The patient had an attack of myalgia, acute bronchitis, and pharyngitis. The bronchitis and pharyngitis were relieved by the suprarenal powder.

CASE VIII.—The patient, a young girl, aged fifteen years, had mitral and aortic regurgitation and a dilated heart; the action of the heart was very irregular and weak; there was no perceptible apex beat seen on inspection. The pulse was 112, weak, and irregular; there were many beats dropped. After the administration of the suprarenal capsule, the mitral murmur became much lessened in volume and intensity, and became localized; the aortic murmur was slightly lessened in intensity; the apex beat was seen on inspection. The pulse was 102, fuller, stronger, and fully regular; all the intermittence had disappeared.

Remarks.—The patient had phthisis pulmonalis, cephalalgia, and anæmia; she was also kyphotic. The cough and headaches were lessened, and the patient felt much improved after taking the drug.

CASE IX.—The patient, a woman, aged thirty-seven years, had a loud, blowing, mitral regurgitant murmur, and an irregular action of the heart. The pulse was 109, weak, and irregular. After the administration of the suprarenal capsule, the loud murmur became less loud and lessened in volume; the action of the heart became regular. The pulse was 109, soft, regular, and full.

CASE X.—The patient, a woman, aged thirty-eight years, had a loud, blowing, mitral regurgitant murmur; the heart's action was weak and irregular. The pulse was 80, weak, very small, and irregular; there was one beat dropped every minute. After the administration of the suprarenal capsule the murmur became much lessened in volume; the normal heart sounds became clearer; the heart acted more strongly and regularly. The pulse was 82, fairly full, regular, and soft.

Remarks.—The patient had taken cardiac depressants; the depressant effects were rapidly overcome by the suprarenal powder.

CASE XI.—The patient, a man, fifty years old, had a loud, blowing, mitral regurgitant murmur, with a very weak and irregular action of the heart; the normal cardiac sounds were muffled. The pulse was 52, very weak, irregular, and trembling; there were many beats dropped. After the administration of the suprarenal capsule the action of the heart became fully regular and stronger; the murmur became diminished in volume, and the normal heart sounds became plainer and more easily distinguished. The pulse was 69, regular, full, and soft; the trembling and the intermittence disappeared.

Remarks.—The patient's headaches were relieved after the administration of the drug.

CASE XII.—The patient, a little boy, aged seven

years, had a double mitral lesion; the normal heart sounds were indistinct. The pulse was 102, slightly irregular, and of fair force. After the administration of the suprarenal capsule, the mitral murmurs became lessened in volume and separated; a distinct difference between them was observed; the action of the heart became fully regular; the normal heart sounds became plainer, and the apex beat was more easily located. The pulse was 102 and regular.

Remarks.—The bronchitis became less annoying and the dyspnoea disappeared.

CASE XIII.—The patient, a woman, forty-three years old, had mitral regurgitation. The pulse was 76, regular, and of good force. After the administration of the suprarenal, the murmur became decreased in volume. The pulse was 76, regular, and not changed.

CASE XIV.—The patient, a woman, aged thirty-four years, had mitral regurgitation with hypertrophy. The pulse was 136, slightly irregular, and weak. After the administration of the suprarenal capsule, the pulse was 109, regular, and strong.

Remarks.—The patient had amygdalitis, which was relieved by the drug.

CASE XV.—The patient, a woman, aged fifty-six, had mitral regurgitation. The pulse was 83, weak, but regular. After the administration of the suprarenal capsule, the pulse was 83, stronger, and regular.

CASE XVI.—The patient, a woman, aged twenty-four years, had a pronounced mitral regurgitant murmur. The pulse was 86, irregular in force and frequency, and weak. After the administration of the suprarenal capsule, the normal heart sounds became more distinct. The pulse was 76, stronger, and regular.

CASE VII.—The patient, a man, sixty-four years old, had mitral regurgitation with a rough aortic second sound. The pulse was 60, regular, and of high tension. After the administration of the suprarenal capsule, the mitral sound became almost inaudible; the rough aortic second sound became smoother; the normal heart sounds became clearer. The pulse was 60, regular, and of lower tension, resembling the normal in tension.

CASE XVIII.—The patient, a man, thirty-eight years old, had mitral regurgitation. The pulse was 83, regular, but weak. After the administration of the suprarenal capsule, the pulse was 81, stronger, fuller, and regular.

CASE XIX.—The patient, a little girl, aged ten years, had aortic stenosis and a hæmic murmur; there were also mitral stenosis and regurgitation. The mitral regurgitant murmur was very loud; the heart was very much enlarged; the apex beat was diffused. The pulse was 120, fairly strong, slightly irregular, and trembling. After the administration of the suprarenal capsule, the mitral regurgitant murmur became softer, lessened in volume, and localized, while the other murmurs and the normal heart sounds became more distinct; the apex beat became localized. The heart was contracted a quarter of an inch on each side; the heaving of the chest with the cardiac impulse was lessened. The pulse was 108, softer, regular, and fuller.

Remarks.—The patient had phthisis pulmonum. The cough was lessened in severity, and the patient felt brighter and stronger.

CASE XX.—The patient, a woman, forty-one years old, had double mitral and aortic lesions. The pulse was 71, irregular in frequency and in force; there were many half beats. After the administration of the suprarenal capsule, the mitral regurgitant murmur became

decreased in volume. The pulse was 71, regular, and stronger; the half beats disappeared.

CASE XXI.—The patient, a woman, forty-eight years old, had double mitral and aortic lesions. The pulse was 70, very irregular in frequency and in force, and very weak. After the administration of the suprarenal capsule, the heart was powerfully stimulated, and acted much more strongly and easily. The pulse was 70, much more regular in frequency and force, and much stronger.

CASE XXII.—The patient, a boy, eleven years old, had a shrill mitral regurgitant murmur; the apex beat was diffused. The pulse was 84, intermittent, weak, and very irregular in frequency and in force. After the administration of the suprarenal capsule, the action of the heart became regular in every respect; the murmur became lessened in volume and less shrill; the diffused apex beat became localized, and the heaving of the chest with each cardiac impulse lessened considerably. The pulse was 72, regular, full, strong, and soft.

Remarks.—The stimulating effects of the drug became apparent within one minute and continued for more than an hour. The patient had inflammatory rheumatism.

CASE XXIII.—The patient, a little girl, two years old, had a mitral regurgitant murmur, enlarged heart, and a diffused apex beat. The pulse was 122, irregular, intermittent, and weak. After the administration of the suprarenal capsule, the murmur and the apex beat became localized; the heart was contracted. The pulse was 112, stronger, nearly regular, and not intermittent.

Remarks.—The patient was very anæmic and weak, but improvement resulted.

CASE XXIV.—The patient, a woman, twenty-seven years old, had mitral regurgitation with a hæmic murmur; there was a diffused apex beat. The pulse was 72, irregular in force and frequency, and very weak, almost imperceptible. After the administration of the suprarenal capsule, the mitral murmur was slightly decreased in volume and the apex beat was localized. The pulse was 76, regular, full, and much stronger.

CASE XXV.—The patient, a boy, eleven years of age, had slight mitral stenosis and regurgitation; compensation was good. The pulse was 101, full, regular, and strong. After the administration of the suprarenal capsule, the regurgitant murmur almost disappeared; at times it disappeared for a longer or shorter period. The pulse was 101.

CASE XXVI.—The patient, a woman, twenty-four years of age, had mitral regurgitation, with an irregular heart's action. The pulse was 96, of fair force, and irregular. After the administration of the suprarenal capsule, the murmur almost disappeared and the heart's action became nearly regular; after a second dose the murmur entirely disappeared. The pulse was 100, stronger, and regular.

CASE XXVII.—The patient, a man, thirty-eight years of age, had aortic stenosis and mitral regurgitation the heart's action was regular, but weak. The pulse was 76, weak, regular, and thready. After the administration of the suprarenal capsule, both murmurs were increased in volume and intensity; the heart's action was stronger. The pulse was 76, stronger, fuller, and softer.

Remarks.—The patient felt much better after the administration of the drug.

CASE XXVIII.—The patient, a woman, twenty years of age, had a very loud mitral regurgitant murmur which was heard all over the chest; there was heaving of the chest with each cardiac beat; the apex beat was in the

sixth interspace, an inch to the left of the left nipple line. The pulse was 128, regular, and hard. After the administration of the suprarenal capsule, the mitral murmurs became slightly lessened in volume and intensity; the heaving of the chest with each heart beat became less marked. The pulse was 102, soft, and regular.

Remarks.—The patient had inflammatory rheumatism, and was relieved of the sensation of the heart beating against the chest, which was the first time that relief had been obtained in three weeks.

(To be concluded.)

THE LAW AND THE INEBRIATE; WITH REMARKS ON THE TREATMENT OF INEBRIETY.*

By JOSEPH COLLINS, M. D.,

NEW YORK.

THE confirmed inebriate needs the aid of his sane brother to save him from the mental and physical decay which is certain to overtake him.

The ordinary means and methods of treating disease are, when applied to confirmed inebriety, not only inadequate, but of comparatively little value. Prolonged abstinence, during which period the vital resistance of the body and mind are enhanced, is the only way of combating the infirmity that gives reasonable promise of success.

This statement summarizes the writer's experience and belief based thereon, and makes it unnecessary to mention or discuss the many "cures" for alcohol and drug inebriety, whose claims the physician and the layman have at one time or another to consider. Any mode of treatment secret, patent, proprietary, natural, supernatural, or scientific, will cure some cases of inebriety, just as any of these measures utilized in the treatment of a neurosis or psychosis of different origin will now and then be successful. But they have been, are, and will continue to be, wholly impotent to make any impression upon inebriety as a scourge to the peoples of the world or to thwart its disease-producing capacity. This gives alcohol and the narcotics a free hand in the production of mental and bodily disease, which they use appallingly. At this date it need scarcely be said that alcoholism is responsible for more insanity, idiocy, and psychical and somatic degeneracy, than any other agency.

Truth it is the most important factor in the causation of mental diseases. If this were not sufficiently grave a charge to lay at its threshold, we need only recall what might be said of it as a social juggernaut and a transformer of morals—things that have been said so often, in language temperate and intemperate, that even sheer reference to it is tiresome. But the reality of it must be admitted. Although the question whether inebriety is a habit or a disease is still debatable, no one can deny that the results of this infirmity constitute disease. Our duty toward disease is plain enough. It is to prevent it and

cure it. No real physician is so unmindful of his high office and rare privilege that he needs to be reminded of his duty in the prevention of inebriety and its effects. In the present status of therapeutics there is but one way to encompass its cure, and that is through prolonged abstinence, during which time the physical strength, mental vitality, and moral tone can be enhanced and the individuality of the victim catered to and nurtured by providing diverting, if not entirely congenial, occupation.

How to bring about this prolonged abstinence is the question that has occupied the attention of sociologists and physicians for many a year. It is universally conceded that in order to reach more than a few inebriates in any community the measure must be compulsory. This can be done only through legislation, and the governments of some countries have endeavored to aid in the solution of the problem by the framing of laws which have for their object the detention of habitual inebriates in institutions or colonies provided for their reception. Before taking any steps looking toward the framing of laws whose enforcement shall provide for the redemption of the inebriate, it seems to me that it is necessary to present a brief up-to-date retrospect of the laws relating to inebriety in this and other countries, to remark on their efficiency or inefficiency, and to call attention to their shortcomings.

The countries whose peoples rank themselves as most advanced in civilization and social economics, Great Britain, Germany, and France, are the ones most derelict in legislation for inebriates. On the other hand, one of Great Britain's colonies, New Zealand, and that little republic, Switzerland, out of which has come so much reformatory legislation of the best kind, have taken the lead.

England has had, since 1879, an Habitual Drunkards' Act. The bill, as originally proposed, contained adequate provisions for effective legislation, but it was necessary to modify it in order to secure its passage, so that from the first it has fallen far short of adequacy to what its framers asked for.

An habitual drunkard is defined as "a person who, not being amenable to any jurisprudence in lunacy, is, notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself, or herself, or to others, or is incapable of managing himself, or herself, or his or her affairs."

Admission to licensed retreats is voluntary only. Written application must be made by the drunkard, stating the time during which he wishes to remain in the retreat. This must be accompanied by statutory declaration by two persons, and attested by two justices, to the effect that the signer is an habitual drunkard and fully understands the meaning of his application. The patient must then enter the retreat of his own accord, but having once entered may not leave until the expiration of the time for which he has signed away his liberty. This term may not exceed twelve months. If he escapes,

the licensee of the retreat must apply to a magistrate for a warrant for his recapture and appearance before a magistrate, who may send him back to the retreat.

Two days after the patient has entered a retreat the licensee must send a copy of the application to the clerk of the local authority and to the Secretary of State. A patient may be discharged at any time by order of the Secretary of State or a judge of the High Court of Justice, or by a local county court judge upon report of any one ordered by him to visit the patient, or by a justice upon a written request from the licensee.

No provision is made under the act for the inebriate who is unwilling to apply for admission to a retreat, or for the pauper. In 1888 an act to amend the original act was passed. The two are known as the Inebriates' Acts, 1879 and 1888. The amendments are in matters of detail, except the removal of the time limit of ten years attached to the first act.

In 1892 a commission was appointed by the government to make inquiry into the results of the Inebriates' Acts and to report on the best mode of treatment for inebriates. This report from the Departmental Committee on the Treatment of Inebriates, presented to both Houses of Parliament in 1893, set forth at length the weaknesses in the acts as they stood and detailed recommendations for effective legislation. The causes assigned for the relative unsuccess of the measures provided were briefly:

1. Want of sufficiently general knowledge of the existence of the asylums.
2. The complicated procedure involved in the admission of patients.
3. The absence of the legal right of committal.
4. The insufficiency of the maximum time for admission (twelve months), and the obstacles in the way of readmission.
5. The difficulty in the way of retaking escaped patients.

Some of these deficiencies are removed by the amendment of 1898, which makes the maximum time of detention two years and allows one justice to suffice as an attesting authority to the signature of the applicant, instead of requiring two. The obstacles in the way of readmission have, in a measure, been removed, inasmuch as a second statutory declaration is not necessary and the justice is not required to satisfy himself that the applicant is an habitual drunkard. A warrant to retake an escaped patient may be issued by any justice.

Despite these additions and improvements, private advices from London inform me that "the act is practically a dead letter, its operation being stopped by the fact of the reformatories not having been provided. Many cases of habitual drunkards come before our London magistrates, but they complain that nothing can be done under the act as scarcely any places are open for the reception of the drunkards."

Far greater progress in legislation for the inebriate has been made in some of the colonies than in England.

The three signal points which commend themselves in the laws existing in Canada and Australia, as in some

States in this country, in contrast to those of England, are:

1. Provision for the commitment of involuntary patients.
2. Simplicity and directness of the method of procedure.
3. Provision for the maintenance of patients who are unable to pay expenses while in a retreat, and the further provision for the enforced payment of such costs by patients who are able but unwilling to meet them.

Australia and New Zealand, perhaps, stand ahead of all other countries in the matter of legislation for inebriates. In South Australia the present provisions are embodied in an act passed in 1881, though as early as 1874 the first Inebriates' Act was passed. Under the last act an incorrigible drunkard is any person who has been convicted of drunkenness three times within a period of six months. Retreats may be licensed by the governor, rules and regulations for the conduct of the establishment, rates of payment, etc., being made by the committee in charge of it, subject to the governor's approval. These rules must also be laid before Parliament according to certain specifications. Any justice of the peace or any one authorized by a justice may visit the retreat and record the condition of the inmates.

Both voluntary and involuntary patients are admitted. In the case of the latter, any person charged with being an incorrigible drunkard before a judge, special magistrate, or two justices of the peace, may, upon the written certificate of two medical practitioners, be committed to a retreat for a period not exceeding twelve months. Such commitment may be made even though the inebriate fails to appear when summoned before the magistrate. An escaped patient may be retaken by any person authorized in writing by the superintendent of the retreat. The judge may direct payment by the inebriate for his board and also the charge of conveyance to the retreat as a judgment debt. After six months' residence a patient may be discharged by the committee of management with the approval of the medical officer. Any relative or any police officer, by direction of a justice of the peace, can obtain a justice's summons calling upon an alleged drunkard to show why a certificate should not be issued that he is an habitual drunkard under the law. This certificate, if issued, remains in force for twelve months. There may be an appeal from any order of justices of the peace to the local court.

Inmates of retreats who are unable to pay for their maintenance are employed at a fair rate of wages, the value going toward the payment of these expenses. A penalty attaches to aiding in the escape of an inmate, and a punishment of from two to three months' imprisonment for insubordination, destruction of property, or wilful disobedience of rules by an inmate.

The Government of South Australia has given £3,000 to the Asylum for Inebriates at Adelaide.

In Victoria, by an act of 1872, provision is made for inebriates, almost identical with that in South Australia.

Committal can be ordered by a county court judge upon statutory declaration by two medical men.

In New Zealand, legislation for the inebriate is included in the Lunatics' Act, 1882. Application may be made to a judge of the Supreme Court for an order for detention by the drunkard himself, or by the parent, husband, wife, child, or friend, in cases where the person has through drunkenness recently wasted his means, failed to provide for his family or threatened violence toward himself or any member of his family. After twenty-four hours from the serving of the notice in writing, the judge may, in the latter case, upon the evidence of not less than two doctors, make a written order for the detention of the drunkard in any asylum or place authorized under the act for lunatics (but in a ward or division where lunatics are not detained) or an institution specially appointed by the colonial secretary for curative treatment, for a period of not more than twelve months. The judge may direct payment by the inebriate, or security for payments. The superintendent may require patients to work under regulations approved by the colonial secretary. The labor is recorded in a book. For refusing to work, a patient may be fined a sum not exceeding £50, to be recovered summarily. The superintendent may employ force to prevent the escape of a patient, or if he fails to return after leave of absence, which may be granted by the medical officer, he may be brought back by order of a resident magistrate. The orders for payments are usually at from twenty to thirty shillings weekly, but in many cases there are no available funds and no payments are made.

In the Dominion of Canada nearly all of the provinces have, by legislation, provided effective measures toward this end.

In Ontario, an act was passed in 1872 to establish a hospital for inebriates. It was modified and extended in 1883, so that it now applies to "any person, male or female, who is an habitual consumer of stimulating or narcotic drugs to such excess as to cause mental or physical derangement or disease."

Admission to hospitals is effected upon written application from the inebriate or upon committal by the Provincial Secretary after inquiry by a judge. In the latter case, such inquiry must be preceded by a petition under oath presented by relatives, or, in default of relatives, by a friend of the inebriate, to the judge of the county of which he is a resident. Committal is for twelve months or less. Poverty is no bar, but those who are able to pay must do so. To secure such payment the property of the inebriate may be sold by the inspector appointed by the lieutenant-governor, subject to review by the county court judge. The lieutenant-governor has power to purchase, equip, and maintain a hospital for inebriates, and the inspector of prisons and asylums has the same power over this retreat as over asylums for the insane.

In Quebec, by act of 1870, any judge of the Superior Court of Lower Canada may pronounce interdiction of

an habitual drunkard, and appoint a curator to manage his affairs and control his person as in interdiction for insanity. In order to regain civil rights, the interdiction must be removed by a judge, which may be done after one year's sobriety. A family council to examine the facts must be called before interdiction be pronounced, but the facts need not be in writing, nor need the drunkard be examined. The judge's decision is final. The curator may place his charge in a licensed home for inebriates and remove him at any time. These homes are licensed by the lieutenant-governor in council and are subject to regulations issued by him. The names of the interdicted are placed upon the general roll of the interdicted. A reputation for drunkenness, based upon common report of the neighborhood, is sufficient to establish a man's status as an habitual drunkard.

On very similar lines, with slight modifications, are the methods sanctioned by legislation for dealing with habitual inebriety in Nova Scotia, New Brunswick, Manitoba, and other provinces.

On the Continent of Europe, Switzerland is the only country that has provided by legislation for the committal of inebriates to special homes for the purpose, though the subject has been repeatedly discussed in France and other countries during the last decade.

In the canton of St. Gall a law was passed in 1891 by which habitual inebriates may be placed in an inebriate asylum for a period of from nine to eighteen months, but for an indefinite period upon a second commitment, either by voluntary application or by direction of the district council, which is the local authority, upon certificate from the medical officer of health. Proceedings may be initiated by a relative or by any public servant. If the subject's personal property is insufficient to defray expenses these are to be met by the public funds. Not only can such charges be applied for, but application can be made for the support of his family during his enforced detention. Other cantons have similar provisions.

In Belgium, drunkenness is regarded as a form of mania, judicially, and under the law a drunkard can be interned in a *maison de santé*.

In Germany and France there are no public asylums for inebriates and therefore no laws on the statute books for their detention. The only measure provided by law for such cases is interdiction, which involves the deprivation of civil rights and the appointment of a guardian.

At the fifth Congrès des médecins aliénistes et neurologistes, held at Clermont-Ferrand in 1892, legislation for inebriates was discussed, and the following resolutions were adopted:

1. That special asylums be founded for the treatment of drunkards.
2. That special measures be taken in regard to habitual drunkards, who constitute a menace to society.
3. That medical "alienists" be consulted in regard to the construction of an asylum for inebriates.

A scheme was presented by the commission of the

Congress to the Chamber of Deputies for the revision of the law of 1838 in regard to public asylums.

There is every reason to believe that France will soon provide laws and sanatoria for the care of her habitual inebriates, but it has not yet been done, as is shown by the following letter of Dr. Pierre Marie:

209 BOULEVARD ST. GERMAIN,
28 Fevrier, 1901.

TRÈS HONORÉ CONFRÈRE:

Je regrette de ne pouvoir vous donner de renseignements sur la question qui vous intéresse, mais nous n'avons en France aucune organisation spéciale pour le traitement des buveurs d'habitude. La seule chose qui existe chez nous c'est une loi punissant l'ivresse; on se contente d'arrêter les gens ivres, on ne les soigne pas, il arrive même trop souvent qu'on les laisse se suicider dans les postes de police.

Le Professeur Joffroy dans son Rapport sur le service des aliénés du département de la Seine pendant l'année 1898 a bien réclamé la création d'asiles spéciaux pour les buveurs d'habitude, mais l'Etat continue à s'occuper plutôt des marchands de vin que de leurs victimes.

Legislation in behalf of the habitual drunkard in the United States has been spasmodic, more or less desultory, and wholly unsatisfactory.

The first effort was made by New York in 1854. The New York State Inebriate Asylum was incorporated in 1857. The object as stated in the charter was "the medical treatment and control of the inebriate." Admissions were either voluntary or by order of a committee on the habitual drunkard. This committee, duly appointed by a justice of a court of record, might commit the drunkard to the custody of the officers of the asylum, there to remain until discharged by the committee. Destitute patients were to be employed in some labor, the payment for which, after expenses for board were deducted, was to be sent to their families, or, if they had none, to be paid to the patients upon their discharge.

The Inebriates' Home, Kings County, was incorporated in 1867. It is empowered to receive patients upon their own application or upon order of the trustees, for a period not exceeding six months. The trustees may choose from those imprisoned in the county jail such as they think fit subjects for the home. Such persons are transferred to the home upon a certificate from the president. A justice may also commit any one who, by return of a commission, is pronounced to be an habitual drunkard and incapable of managing his or her affairs. The maximum time for committal is one year. This home has received contributions from the fees paid for liquor licenses and for violation of excise laws. By the act of 1875, this annual modicum was fixed at twelve per cent. of the license moneys.

Under a special enactment of the New York legislature of 1887, St. Saviour's Sanatorium, at Inwood, N. Y., was empowered to receive and detain females com-

mitted by a magistrate on the certification of inebriety by two registered examiners in lunacy. The operation of the law has been fairly satisfactory, although lately its constitutionality has been questioned.

By act of Illinois, 1867, the officers of the Washington Home of Chicago, incorporated in February of that year, may receive and detain until the expiry of the sentence any person sentenced by the authorities of the city of Chicago for intemperance or any misdemeanor caused thereby. They may also require the inmates to work. The home receives ten per cent. of all drink license fees.

By act of the State of Connecticut, 1874, the court of probate for the district can issue an inquiry into the allegation that a person is an habitual drunkard or dipsomaniac, made in an application of a majority of the selectmen of the town in which he resides. Upon the allegation being proved to be true and upon the attested certificate of two physicians, the individual may be committed to an inebriate asylum in the State for from four to twelve months if an habitual inebriate, and for three years if a dipsomaniac. Patients may be allowed out on probation, and a Supreme Court judge can order discharges upon information of unjust detention.

In New Jersey, any judge can, on the sworn certificate of two physicians of good standing, commit a drunkard to a home or hospital for such a time as the officers thereof deem necessary. In destitute cases the cost of maintenance is defrayed from the poor tax or from the moneys collected for liquor licenses by the county or city from which the inebriate was received.

Massachusetts has a State Hospital for Inebriates, in which the cost of board and treatment, when the patient is unable to pay, is met by the municipality in which he resides.

In Texas, one hundred thousand dollars was recently appropriated by the legislature for the construction and equipment of an institution for the treatment of inebriates.

In Pennsylvania, if there is no committee of an habitual drunkard, an inebriate can be received and detained by the proper officer of the Pennsylvania Sanitarium, incorporated in 1867, upon presentation, by his guardian or friend, of a certificate by two physicians, attested by a judicial officer having power to administer oaths.

A bill, to be introduced at the coming session of the Indiana legislature, provides that any habitual drunkard who is a public charge or likely to become a public charge may, on application to the county judge, either in person or by friend or near kin, making oath to the facts in the case, be sent to an institution in which inebriates are cured (*sic.*) The expense, not to exceed \$100. is to be paid by the county of which the beneficiary is a resident.

Such is a brief survey of the law and the inebriate abroad and at home.

Therapeutical Notes.

For Catarrhal Aphonia.—The *Journal de médecine de Bordeaux* for March 17th quotes the following from the *Quinzaine médicale*:

- R Sodium benzoate. 90 grains;
- Alcoholate of aconite root. 20 drops;
- Cherry laurel water. 45 minims;
- Syrup of tolu, } of each. 450 grains;
- Syrup of codeine, }
- Water. 900 minims.

M. To be taken in four equally divided doses in the twenty-four hours.

A dry compress of cotton, retained with a flannel bandage, should be applied to the throat during the night.

The Prescribing of Sodium Glycerophosphate.—It is often forgotten by physicians that the physical characteristics of sodium glycerophosphate are such as to render this salt unsuited to dispensing in any form but that of a watery mixture. Although a solid, it is of a thick paste-like consistence, and is therefore not to be prescribed in solid form with other powdered drugs; neither is it desirable to prescribe it in pills, capsules, or cachets, since, owing to its deliquescent properties, a large bulk of dry excipient would have to be added. The best form in which to prescribe it is probably in twenty-five-per-cent. aqueous solution, a teaspoonful of which will then contain fifteen grains of the salt. This may be administered in water, alone or combined with other drugs or flavoring agents.

For Constipation in Children.—The *Revista de la Asociacion medico-farmacéutica* for December, 1900, quotes the following prescriptions from the *Journal des praticiens*:

- R Sodium bicarbonate. 180 grains;
- Powdered rhubarb. 10 “
- Sodium sulphate. 480 “
- Essence of peppermint. 20 drops.

M. From half to one level teaspoonful of this powder, fasting in the morning.

Or:

- R Manna. 480 grains;
- Calcined magnesia, } of each. 960 “
- Sublimated sulphur, }
- Honey. 480 “

M. From one level teaspoonful to a tablespoonful dissolved in a cup of hot milk, to be taken night and morning.

Silver Nitrate and Copper Sulphate in the Treatment of Chronic Urethritis.—In his translation of de Keersmaecker and Verhoogen's treatise, entitled *Chronic Urethritis of Gonococcic Origin*, recently published, Dr. Ludwig Weiss inserts the following addition to the authors' remarks on various astringents: "The use of any of these remedies at the proper time would be of great benefit to the patient and a source of satisfaction to the physician. But we must confess that hitherto the indications for their employment have been so vague that it borders almost on intuition to choose the right one. We are, therefore, indebted to Finger, who quite recently expounded the use of nitrate of silver and sulphate of copper in chronic gonorrhœal urethritis. For the recent superficial lesions, because only such are amenable to injections or instillations, he recommends the nitrate of silver; for older ones, the sulphate of copper. He draws

a happy parallel with the treatment of trachoma of the conjunctiva. There the catarrhal symptoms are combated with silver, while the older processes are attacked with the sulphate of copper in substance. The same indications hold good for chronic urethritis, with this modification: In recent cases of chronic urethritis, where gonococci are yet present, nitrate of silver should be employed; in inveterate cases, where no gonococci are present in the filaments, the sulphate of copper will prove effective. The nitrate of silver in one-half- to five-per-cent., the sulphate of copper in five- to ten-per-cent. solutions.

"It is best to begin with the milder percentages, in order to test the reaction of the urethra. If stronger solutions are well borne, we will employ a glycerin solution of them instead of an aqueous one. The glycerin possesses great affinity for moisture, and will imbibe deeper than a watery vehicle. Finger recommends also the use of a lanolin salve to be used through Tommasoli's salve syringe."

The Treatment of Chalazion.—*Nord médical* for March 1st ascribes the following to Strzeminski:

- R Pure iodine. 3 grains;
- Potassium iodide. 9 “
- Lanolin. 1 drachm;
- Vaseline, } of each. 12 grains.
- Distilled water, }

M. This ointment is applied by the patient to the affected part at bedtime, and allowed to remain on all night. It does not provoke pain or stain the skin. It goes without saying that during the existence of the chalazion and after its disappearance, conjunctivitis, blepharitis, and atresia of the lacrymal duct, if present, must also be treated. In tuberculous or "scrofulous" patients general treatment is also called for.

For Dentition.—The *Journal de médecine de Bordeaux* for February 24th gives the following:

- R Citric acid. 8 grains;
- Distilled water. 8 minims;
- Cocaine hydrochloride. $\frac{3}{4}$ of a grain;
- Syrup. 150 drops;
- Syrup of saffron. 150 “
- Tincture of vanilla. 12 “

M. To be rubbed into the gums during dentition.

For Urinary and Fæcal Incontinence in General Paralysis.—M. Athanassio (*Arte medica*, April 7th) recommends the following formula:

- R Tartrate of iron and potassium. 15 grains;
- Tincture of nux vomica. from 225 to 300 drops;
- Decoction of rhatany. } of each. 1,500 minims.
- Decoction of cinchona, }

M. To be taken in equally divided doses in the course of two days.

The Local Application of Turpentine for Neuritis.—Mircoli (*Clinica medica della R. Univ. di Genova*; *Arte medica*, April 7th) highly praises the use of frictions of turpentine in neuritis due to cold, and especially in sciatica. He uses:

- R Venetian turpentine. 30 parts;
- Dissolve in
- Oil of turpentine. 6 “
- And add
- Olive oil. 50 “

The turpentine resin, adhering to the skin, exerts a continuous action after the cessation of the frictions.

NEW YORK, SATURDAY, MAY 4, 1901.

GYNÆCOLOGY AND SURGERY AMONG THE
ANCIENTS.

THERE have been times when we have been tempted to deplore the decadence of scholarship in the medical profession; of literary scholarship, we mean, as distinguished from a study of medical literature merely from the standpoint of utility and for purposes of applied medical science. We have been inclined to look back with regret to the days when great physicians were almost universally great scholars, *i. e.*, learned in much of the learning that was then attainable outside of those things pertaining to the practical application of their knowledge. We have always gladly noted any instance of devotion to such scholarship, and it is with pleasure that during the last years of the century that has closed we have witnessed an unmistakable increase in the bent toward it displayed by the profession at large. To say nothing of members of our craft who have entered upon the paths of general literature, some of them, like Dr. Weir Mitchell, attaining no mean eminence therein, increasing interest in medical scholarship has been illustrated by increasingly numerous contributions to professional journals on matters of medical history, biography, archæology, and folklore. A work suggesting these reflections,* by an Australian physician, will be welcomed by all lovers of scholarly research. It is safe to say that it was a labor of love, for no man who had not all the essential instincts of the scholar would have undertaken such a laborious task; and that fact alone would lead us to expect what we actually find in the work, a perfect storehouse of information concerning the attainments of the ancients in the field of gynæcology. Indeed, the author gives us the keynote of his spirit in the

following felicitous quotation from Robert Louis Stevenson:

"I know not how it is with you:
I love the first and last—
The whole field of the present view,
The whole flow of the past."

In 302 pages, Dr. McKay surveys in its continuity the literature of ancient gynæcology, Egyptian, Hindu, Greek, Alexandrian, Roman, and Byzantine. He deals in detail with the great professors of the art and with the encyclopædists whose labors have preserved for us much of the knowledge of their times and of those which had preceded them—Hippocrates, Celsus, Pliny, Rufus Ephesius, Dioscorides, Soranus, Aretæus, Galen, Oribasius, Moschion, Aetius, Paulus Ægineta, and the Arabian writers from Bagdad in the east to Cordova in the west. From the Papyrus Ebers, of the sixteenth century B. C., to "old Avicenna" (A. D. 980) and Albucasis on the threshold of the Middle Ages, he has sought out, and actually transcribed for our startled interest, almost every original mention that is made of matters gynæcological. The importance of such a work is incalculable. The diseases of women, more than any other subject in medicine, are of interest, not only to the specialist and the distinguished physician, but to every practitioner.

The establishment and legitimization of operations involving abdominal section is regarded as, perhaps, the greatest triumph of nineteenth century surgery. Can we, then, fail to be more than interested, even fascinated, by the following description of the abdominal operation as laid down as a recognized procedure of surgery in the Hindu Upavédas, a supplement, so to speak, to the Brahman Védas? Of these, the Ayur-Véda contains the medical writings, respectively the Charaka-Samhita and the Insruta-Samhita. Dr. McKay says:

"Taking for granted that these works were written 500 B. C., then the following passages are the first mention of such operations; but if these works date later than this, then the Alexandrian surgeons have a prior claim, for we shall see later on that they deliberately operated on the abdominal organs. In the chapter on Enlargement of the Abdomen (Udara) the following passage occurs: . . . 'When the remedies [in obstruction of the bowels] are of no use and the situation of the patient desperate, an operation is recommended, which is to be performed in the following manner: Below and on the left side of the umbilicus, and four fingers' breadth from the linea alba, an incision is to be made four fingers' breadth in length, and the breadth of four fingers of the gut is to be drawn out, and the substance, whether hair, or stone, or a bad secretion, which was the

**The History of Ancient Gynæcology.* By W. J. STEWART MCKAY, M. B., M. Ch., B. Sc., Senior Surgeon to the Lewisham Hospital for Women and Children, Sydney, etc. New York: William Wood & Company, 1901. Pp. xx-302.

cause of the disease, is to be removed. Ghee and honey is to be rubbed over the wound in the intestine, and it is then returned into the abdomen. Apply sutures, and treat the internal wound as recommended in such cases.' ”

Passing to the Alexandrian period, we find that Erisistratus deliberately operated on the liver and spleen in cases of tumor, while Xenophon, of Cos, a follower of Erisistratus, appears to have been the first to ligate vessels as a means of checking hæmorrhage. Later still, we find the following picture of Roman medicine in the time of Trajan (98 to 117 A. D.) :

“Heliodorus, a contemporary of Juvenal, appears to have practised amputation by the flap method, while plastic surgery was everywhere in vogue. Tracheotomy and operations for curing cataract were attempted with success, while lithotomy and lithotripsy were common operations in the hands of specialists. An abscess of the liver would be opened if diagnosed, and the radical cure for hernia and for stricture of the urethra was not uncommon; while specialists operated on the female genital organs, removing small growths from the cervix, sometimes attempting hysterectomy, and performing plastic operations in cases of atresia and other conditions; for the speculum vaginae was in use before the year 79 A. D., in which year Herculaneum and Pompeii were destroyed, for in the ruins of these cities a three-bladed speculum was discovered at the beginning of this century. In obstetrical cases, when the necessity arose, the child was removed by the operation of embryotomy, and Cæsarean section was occasionally practised.”

The pages from 240 to 302, inclusive, are occupied by a categorical résumé of the facts accumulated from the quotations given in the preceding part, the various items being dealt with under three sections, viz., the Anatomy of the Female Genital Organs, Physical Examinations of the Genital Organs (including a summary of the history of the instruments and methods employed), and the Diseases of Women, as known to the ancients.

Many subjects of incidental interest are also considered, among them the conditions as regards morals and licentiousness of various ages, particularly the era of Imperial Rome. The author cites Lauder Brunton (*The Action of Medicines*, p. 553) to the effect that Agrippina, Faustina, and Messalina, each one of whom, though inhabiting a palace, yet frequented the brothel and conducted themselves as common prostitutes, were probably plagued with vaginal eczema; and slyly prods the “chemical blonde” with the reminder that Messalina wore a yellow wig on her visits to the brothels, in com-

pliance with the Roman law that prostitutes should dye their hair either blue or yellow.

Dr. McKay considers in several places the vexed question of whether venereal diseases were known to the ancients. It is an indisputable fact that in the literature of Greece and Rome no passages exist pointing unequivocally to diseases communicable by sexual intercourse. Speaking of the vice and depravity depicted by Juvenal and Martial as existing in Rome, the author says: “Amidst such depravity we should have expected to find venereal diseases thriving apace, yet, strange to say, no author has left us such a description of gonorrhœa as will enable us to say that that disease really existed in those days.” Celsus, it is true, has left us an excellent picture of balanitis, phimosis, and orchitis, but he nowhere states that these conditions were attributable to sexual intercourse. The term *γονόρροια* is used by Rufus, Aetius, and Paulus Ægineta, and, we may add, by Galen—but the context, in some places at any rate, clearly indicates that, not gonorrhœa, but what we now term spermatorrhœa is meant. Various passages bearing upon the question are also discussed from the books of Moses, Herodotus, Juvenal, and Martial, and the author seems to have arrived at what appears to be the inevitable conclusion that venereal disease, or at any rate gonorrhœa, was well known and had its share in the ætiology of women’s diseases even then, but, as Celsus says, *invitissimus quisque alteri ostendit*. We know that, even in the present day, many who are shameless in speaking freely and wantonly of vice are very reticent in alluding to its loathsome consequences. In the light of Havelock Ellis’s tracing of the relation of modesty to the fear of exciting disgust, this is in no way surprising. Martial (xi, 62), however, speaks of a *morbus indecens*. Moreover, in a papyrus recovered in the last decade of the nineteenth century from an Egyptian mummy case, of which some account was published in the *Lancet* for February 18, 1899, there is a passage, unnoticed by the present author, in a fragment by one Herondas, a Greek poet probably of the period of Theocritus, which seems from the context to bear reference undoubtedly to a venereal disease. In this piece, one Metro seeks to learn, from another woman named Koritto, the maker of a phallus used for masturbation. Koritto discovers that her phallus has been lent by Eubule, to whom she herself had lent it, to another woman, Nossis, whereupon Koritto exclaims indignantly,

“*χιλίων εὐντων*
ἐν’ οὐκ ἄν ὅστις λεπρός ἔστι προσδώσω.”

“Though I had a thousand I would not give her another

one, even though it were infected with disease." It may seem that to assign the meaning of *venereal* disease to *λεπρός* is begging the question; but in view of the context it seems to us pretty clear that the kind of disease meant is such a special infection as would be likely to attach to such an instrument used for such a purpose—surely, a venereal disease.

The author asks for indulgence on the score that the book was "written in a country where every book that one wants to refer to has to be brought from Europe, and often one must wait, not for months, but for years, before some of these works can be procured." We refer to this apology as an evidence of the author's earnestness and modesty; it is entirely unnecessary.

The book is fitly dedicated to the late Lawson Tait, whose untimely death deprived the author of valued criticism and aid in revision, and we cannot refrain from quoting the author's tribute to one of the greatest of great men, a tribute which, we feel sure, will meet with a responsive echo in many hearts on this side of the Atlantic Ocean:

"There is but one sad memory connected with this work. Mr. Lawson Tait, my teacher and friend, had from the outset encouraged me to undertake this task, and, with his usual impulsive generosity, had agreed to read it through, and to write an introductory chapter on the subject with which his name must be forever connected; for who will deny that he has added to the advancement of operative gynecology more than any one who has preceded him? This man was a genius, and if ever man took a knife into his hand who understood his work, this was the man. He had a brain that was omniscient; he came to his work primed with the experience of the difficulties of 3,000 cases of abdominal section; he dealt with each case with a master's hand, not with the empiric touch that so many display. Those who knew him intimately knew him to be a genius; and when the tongue of envy has ceased, and age has paid its just tribute to this man, then, and not till then, will gynecologists acknowledge their real indebtedness to this great and marvellous surgeon."

OUR SUBSCRIBERS' DISCUSSIONS.

IN our department of News Items, in the article headed Special Notice to our Subscribers, in this issue of the *Journal*, we briefly outline a new feature which, we believe, will be of great value to our readers. Primarily, our object is to obtain a number of expressions of opinion, always on some subject of everyday interest to the general practitioner, from the "rank and file" of

the profession, those who do the great bulk of family practice. As a rule, such practitioners have very decided convictions founded on their own personal experience, convictions for which they are able to give very good reasons. They are apt, however, to be too modest and reserved in the matter of bringing their opinions to the attention of their fellow physicians. They are prone to saying that they "know nothing of the art of writing." It is for this reason that, in the friendly competition which we expect to establish, we have decided that literary style shall have no weight in deciding the awards.

There might at the first glance seem to be no good reason for our declining to award the prize to an individual more than once in any one year. There is, however, what we look upon as an excellent reason; it is to handicap those who, possessed of some literary facility and to some extent skilled in the art of "brushing up" in a subject by resorting to libraries, might otherwise have an undue advantage over the plain, practical physicians who, while lacking these facilities, are still likely to be more experienced and better able to interpret their own experience aright. It is for the same reason that we exclude persons engaged in work on medical journals.

The amount of the prize is purposely made moderate. Large prizes have their usefulness—and great it is—in drawing forth essays that can only be the fruit of prolonged and laborious investigation, a minute acquaintance with literature, and very careful thought; to call forth practical expressions from practical physicians—and that is the particular object we have in view in these discussions—we believe a small award, frequently repeated, will be more efficacious.

THE DANGER OF FLANNELETTE.

THE *Lancet* for March 30th comments editorially upon the danger of flannelette as a material for clothing in consequence of its extreme inflammability. It is said to ignite "with the most dangerous ease, burning with a hot bluish flame not unlike the flame of burning alcohol and once a-light it is well-nigh impossible to extinguish it." The burning to death of a child, six years of age from the ignition of its flannelette night dress, in spite of the efforts of the mother to extinguish the flames, forms the text for this comment. The *Lancet* has tested the material again and again and finds that "it takes fire instantly . . . a hot blue flame shooting along the surface and increasing most rapidly in size and in intensity." The dangers of celluloid for articles of attire have been frequently pointed out, but it would seem to us that if the *Lancet's* findings are substantiated, flannelette

nelette, owing to its much more frequent use and the larger masses employed, in some instances enveloping nearly the whole body, is likely to prove a far more generally dangerous article of wear.

RECKLESS CAR SPEEDING.

THE serious accident to a Fifth Avenue stage, in which six persons were seriously, if not in some instances fatally, injured by the crashing into it, on April 30th, of a Madison Avenue car, should direct the attention of the proper authorities to the recklessness with which cars, and other vehicles, for that matter, are constantly driven over the more important and thronged street crossings. It is only fair to say that in the instance referred to the testimony of eye witnesses gives credit to the motorman for doing all in his power to avoid or at least minimize the catastrophe. We do not desire to prejudge the merits of this or any case in which a proper investigation will apportion the responsibility, but we desire to express our strong opinion that some regulation requiring a speed no greater than that of a horse's walk should be officially ordered for all the important crossings, and that the onus should be laid upon some one of enforcing it.

THE PATHOLOGICAL INSTITUTE OF THE NEW YORK STATE HOSPITALS.

IN consequence of legislative crippling of the institute, including the enforced retirement of the director, Dr. Ira Van Gieson, his entire staff of associates have resigned. Nothing could better demonstrate the short-sighted nature of the policy which, against the protest of a great number of medical men and others distinguished in matters of research, has been pursued toward the institute.

THE CHANCE OF SUCCESS IN PRACTICE IN THE FAR WEST.

THE old mistake of taking it for granted that almost any graduate of an Eastern medical school had only to go to the far West to find a remunerative practice awaiting him has, we believe, been well-nigh corrected. It must still be made in a considerable number of instances, however, for Dr. W. James Howells, of Spokane, writes to us cautioning young graduates against it. He says that they will find in the State of Washington a sufficient number of physicians, as many as one for every four hundred inhabitants in the large towns, and that they are men of good attainments who keep pace thoroughly with the progress of medicine. This we do not in the least doubt. At the same time there is always the hope of pitching upon a community that is destined to grow rapidly, and that it is, we take it, rather than any false sense of superiority to his Western brethren, that generally induces a man to go from the East to the far West.

News Items.

Society Meetings for the Coming Week:

- MONDAY, *May 6th*: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.
- TUESDAY, *May 7th*: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society; Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).
- WEDNESDAY, *May 8th*: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Pittsfield, Massachusetts, Medical Association (private); Philadelphia County Medical Society.
- THURSDAY, *May 9th*: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y. (annual); South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.
- FRIDAY, *May 10th*: Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.
- SATURDAY, *May 11th*: Obstetrical Society of Boston (private).

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending April 27, 1901:

DISEASES.	Week end'g Apr. 20		Week end'g Apr. 27	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	22	13	20	7
Scarlet Fever.....	729	37	669	44
Cerebro-spinal meningitis.	0	4	0	6
Measles.....	280	10	330	9
Diphtheria and croup.....	272	45	290	58
Small-pox.....	38	10	56	8
Tuberculosis.....	248	185	287	204

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending April 27, 1901:

- ARNOLD, W. F., Surgeon. Detached from duty at Olongapo, Philippine Islands, and ordered to the *New Orleans*.
- DENNIS, J. B., Assistant Surgeon. Detached from the Naval Academy, Annapolis, and ordered to the *Chesapeake*.
- ROGERS, F., Medical Inspector. Ordered to the *Brooklyn* for duty as fleet surgeon of the Asiatic Station.
- SMITH, C. G., Assistant Surgeon. Ordered to the *Vermont*.
- STOKES, C. F., Surgeon. Ordered to the Cavite Naval Station, Philippine Islands, to await the arrival of the *Solace*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from April 20 to April 27, 1901:

- BUSHNELL, GEORGE E., Major and Surgeon, United States Army, is granted leave of absence for fourteen days, to take effect upon the expiration of his present sick leave.
- GILL, CHARLES R., Captain and Assistant Surgeon, is granted leave of absence for two months on surgeon's certificate of disability.
- GRAVES, LEONARD K., Captain and Assistant Surgeon, is granted leave of absence for one month.
- RAYNOR, WILLIS J., Captain and Assistant Surgeon, United

States Volunteers, is granted leave of absence for one month, to take effect on or about May 10, 1901.
 VAUGHAN, MILTON, Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.
 WILLIAMS, A. W., First Lieutenant and Assistant Surgeon, will proceed to New York to report as to the cause of the death of J. P. Hatch, General, United States Army.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague, were reported to the surgeon-general during the week ending April 26, 1901:

Smallpox—United States and Insular.

Newcastle, Delaware.....	Apr. 1-15.....	4 cases.	
Jacksonville, Florida.....	Apr. 13-20.....	6 cases.	
Chicago, Illinois.....	Apr. 13-20.....	17 cases.	
Cynthiana, Kentucky.....	Apr. 17.....	6 cases.	
Lexington, Kentucky.....	Apr. 13-20.....	4 cases.	
New Orleans, Louisiana.....	Apr. 13-20.....	10 cases.	1 death.
Winona, Minnesota.....	Apr. 13-20.....	2 cases.	
Manchester, New Hampshire..	Apr. 13-20.....	7 cases.	
Jersey City, New Jersey.....	Apr. 14-21.....	4 cases.	
Cincinnati, Ohio.....	Apr. 12-19.....	7 cases.	
Cleveland, Ohio.....	Apr. 13-20.....	46 cases.	
Pittsburgh, Pennsylvania.....	Apr. 13-20.....	1 case.	
Steelton, Pennsylvania.....	Apr. 13-20.....	3 cases.	
Nashville, Tennessee.....	Apr. 13-20.....	1 case.	
Wheeling, West Virginia.....	Apr. 13-20.....	1 case.	
Manila, Philippines.....	Mar. 2-9.....	8 cases.	
San Juan, Porto Rico.....	Apr. 6.....	13 cases.	

Smallpox—Foreign.

Prague, Austria.....	Mar. 23—Apr. 6	8 cases.	
Antwerp, Belgium.....	Apr. 6.....	3 cases.	1 death.
Hong Kong, China.....	Mar. 2-9.....		6 deaths.
Paris, France.....	Mar. 31—Apr. 6		10 deaths.
Gibraltar.....	Apr. 1-7.....	2 cases.	
Southampton, England.....	Apr. 6-13.....	3 cases.	
Glasgow, Scotland.....	Apr. 6-13.....		5 deaths.
Leith, Scotland.....	Mar. 31—Apr. 6	1 case.	
Bombay, India.....	Mar. 19-26.....		12 deaths.
Calcutta, India.....	Mar. 16-23.....		144 deaths.
Karachi, India.....	Mar. 9-16.....	12 cases.	8 deaths.
Madras, India.....	Mar. 16-22.....		10 deaths.
Progreso, Mexico.....	Mar. 31—Apr. 6	4 cases.	
Merida, Yucatan, Mexico.....	Apr. 11.....		Prevalent.
Rotterdam, Netherlands.....	Mar. 31—Apr. 6	1 case.	
Odessa, Russia.....	Mar. 31—Apr. 6	13 cases.	1 death.
Corunna, Spain.....	Mar. 31—Apr. 6		1 death.
Vigo, Spain.....	Mar. 1-31.....		1 death.

Yellow Fever.

Panama, Colombia.....	Apr. 8-15.....	8 cases.	
Cape Haitien, Haiti.....	Mar. 23-30.....	1 case.	1 death.
Coatzacoalcos, Mexico.....	Apr. 1.....		Prevalent.
San Salvador, Salvador.....	Mar. 31.....	4 cases.	3 deaths.

Cholera.

Hong Kong, China.....	Mar. 2-9.....		1 death.
Bombay, India.....	Mar. 19-26.....		4 deaths.
Calcutta, India.....	Mar. 16-23.....		65 deaths.
Madras, India.....	Mar. 16-22.....		1 death.
Singapore, Straits Settlements.	Feb. 26—Mar. 2		5 deaths.

Plague—Insular.

Manila, Philippines.....	Mar. 2-9.....		8 deaths.
--------------------------	---------------	--	-----------

Plague—Foreign.

Hong Kong, China.....	Mar. 2-9.....		16 deaths.
Bombay, India.....	Mar. 19-26.....		886 deaths.
Calcutta, India.....	Mar. 16-23.....		1,040 deaths.
Karachi, India.....	Mar. 19-26.....	239 cases.	192 deaths.
Singapore, Straits Settlements.	Feb. 26—Mar. 9		3 deaths.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending April 25, 1901:

GIBSON, L. P., Acting Assistant surgeon. Granted leave of absence for seven days.
 GLENNAN, A. H., Surgeon. To proceed to Tallahassee, Florida, for special temporary duty.
 KING, W. W., Assistant Surgeon. To proceed to Guayanilla, Porto Rico, for special temporary duty.
 MCINTOSH, W. P., Surgeon. To proceed to Ducktown, Tennessee, for special temporary duty.
 MATHEWSON, H. S., Passed Assistant Surgeon. To proceed to Ponce and Guayanilla, Porto Rico, for special temporary duty.

MEAD, F. W., Surgeon. Department letter of January 11th, granting him leave of absence for sixty days, is amended so that said leave shall be for one month and twenty-four days.
 NYDEGGER, J. A., Passed Assistant Surgeon. To proceed to Cape Charles Venture, Virginia, for special temporary duty.
 PATTUS, W. J., Surgeon. Department letter of January 11th, granting him leave of absence for two months, is amended so that said leave shall be for one month and twenty-seven days.

RODMAN, J. C., Acting Assistant Surgeon. Granted leave of absence for seven days from April 24th.

WATTERS, MARK H., Hospital Steward. Relieved from duty at Chicago and directed to proceed to St. Louis and report to the medical officer in command for duty and assignment to quarters.

WERTENBAKER, C. P., Passed Assistant Surgeon. To represent the service at meeting of the Texas Medical Association, Galveston.

Changes of Address.—Dr. Aaron Denenholz, to No. 85 East Tenth Street, New York; Dr. Joseph E. Lumbard, to No. 1945 Seventh Avenue, New York; Dr. Henry S. Norris, to No. 10 West Forty-ninth Street, New York.

A Physician's Bequest for the Temperance Cause.—Dr. Charles Dana, of Tunkhannock, Pa., who recently died in Florida, appropriated the sum of \$2,000 to be used in furthering the cause of temperance and aiding the prohibition movement.

The New Bureau of Bacteriology and Pathology.—Commissioner Daniel Lewis, of the State Department of Health, has appointed Dr. George Blumer, of the Bender Laboratory, of Albany, director of the new Bureau of Bacteriology and Pathology. It will be one of the most important bureaus under the Health Commissioner.

French Savant Studying New York's Birth Rate.—Jules Siegfried, ex-Minister of Commerce of France, in this country to study municipal government and industrial conditions, visited the Health Department at New York on April 22d. M. Siegfried was greatly interested in the statistics of births and deaths. The birth rate in France is decreasing to an alarming degree, and inquiry on the subject as to the cause has already been made by the French Government.

A St. Louis Physician Celebrates his Golden Wedding.—On April 22d Dr. and Mrs. Charles Tuckett, of St. Louis, celebrated the golden anniversary of their wedding. The doctor is seventy-five years old and his wife is seventy-three. They are the parents of ten living children. Dr. Tuckett has been a practising physician in St. Louis for over fifty years. He is as active as most men at fifty years of age. He takes a daily ride on his bicycle and is as young in spirit as any of his children.

Special Notice to our Subscribers.—Under the title of Subscribers' Discussions, we are about to introduce a new feature into the *Journal*. As the title indicates, it will consist practically of discussions by our subscribers. We shall announce the topics in advance, for the most part in the form of questions. The question for the first discussion is as follows: *What is the Best Way of Treating the Stump of the Umbilical Cord?* Whoever among our subscribers answers this question in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested

that the answers be short, no one answer to contain more than six hundred words. We shall publish the substance of such of the answers as seem to us most likely to prove interesting to our readers, and we reserve the right to publish any of the answers as original communications, but most of them will appear under the head of Subscribers' Discussions.

Only subscribers to the *New York Medical Journal* will be entitled to compete, and all the members of our own editorial staff are disqualified, as are also all persons known to be engaged in medical journalism. Moreover, this prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. Answers to the first question must reach us on or before June 10th, and we shall announce the award as soon thereafter as practicable. It is our present intention to give out these questions once a month, and they will all be on subjects of interest to the general practitioner. For further information, see the editorial article entitled Our Subscribers' Discussions.

St. Louis Medical Society of Missouri.—At the meeting held on April 20, 1901, papers were read on Pessimism in Cancer, by Dr. G. Wiley Broome, and on Some Complications of Syphilis of the Skin and their Treatment, by Dr. Martin F. Engman.

The Missouri Medical Association will meet at Jefferson City on May 21st, 22d, and 23d. Sessions will be held in the hall of the House of Representatives. Local committees have in preparation several receptions and other entertainments for the visitors.

The Society of the Alumni of the Sloane Maternity Hospital held its fourth annual dinner at the New York Athletic Club, on April 26th, under the presidency of Dr. Samuel M. Brickner. Among the speakers were Dr. James W. McLane, Dr. Edward B. Cragin, Dr. Eugene Coleman Savidge, Dr. James D. Voorhees, and Dr. Charles A. Elsberg. Dr. Walter M. Brickner delivered a mock obstetrical lecture. Dr. H. P. de Forest was elected president for the current year.

The German Medical Society of the City of New York.—The programme for the next meeting, to be held on Monday evening, May 6th, at the Academy of Medicine, includes the exhibition of patients, specimens, instruments, etc.; a demonstration of stereoscopic Röntgen-ray photographs, by Dr. C. H. Jaeger; one of a new amygdalotome, by Dr. Max Toeplitz; one of a case of congenital coloboma of the upper eyelid; one of a case of costopleurectomy and one of a case of melanosarcoma, by Dr. Carl Beck; and one of specimens of gynaecological diseases of general interest, by Dr. F. Foerster; also a paper on Chancre of the Nasal Mucous Membrane, by Dr. W. Freudenthal.

The American Congress of Tuberculosis will hold its second annual meeting at the Grand Central Palace, in the city of New York, on May 15 and 16, 1901, in joint session with the Medico-Legal Society of New York. A dinner will be given to the members and guests. It is proposed to open a museum of pathology, bacteriology, and public health, with an exposition of electrical and other instruments and of all appliances used in any way in arrest or treatment of the disease.

Delegates to the American Congress of Tuberculosis.—The governor of Colorado has appointed the following physicians to represent that State at the congress to be held in the city of New York May 15 to 17, 1901: Dr. J. N. Hall, of Denver; Dr. W. B. Davis, of Pueblo; Dr. B. P. Anderson, of Colorado Springs; Dr. J. Tracy Mellvin, of Saguache; Dr. R. F. Graham, of Greeley, and Mrs. W. S. Decker, of Denver. The governor of Kentucky has appointed the following: Dr. J. N. McCormick, of Bowling Green; Dr. M. K. Allen, of Louisville, and Dr. Chester Mayer, of Louisville. The governor of Vermont has appointed the following: Dr. Charles S. Caverly, of Rutland; Dr. Henry D. Holton, of Battleboro, and Dr. Truman R. Stiles, of St. Johnsbury. The Nicaraguan Minister at Washington has appointed the following Nicaraguan physicians to represent Nicaragua: Dr. Louis H. Debayle, 21 Irving Place, New York, and Dr. Juan B. Sacasa, Columbus Hospital, New York. The governor of Missouri has appointed the following: Dr. E. L. Priest, of Nevada; Dr. R. L. Wills, of Neosho; Dr. Frank J. Lutz, of St. Louis; Dr. Wm. F. Kuhn, of Kansas City; Dr. J. T. McClanahan, of Boonville; Dr. J. G. Martin, of Kahoka; Dr. G. A. Goben, of Kirksville; Dr. S. A. Proctor, of Doniphan; Dr. C. H. Fulbright, of St. James; Dr. S. H. Rigg, of Middletown; Dr. W. E. Shelton, of Appleton City; Dr. S. C. Davis, of Warsaw; Dr. E. H. Chinna, of Rocheport; Dr. W. B. Davis, of St. Joseph; Dr. C. W. Chastine, of Plattsburg; Dr. R. L. Hamilton, of Richmond; Dr. W. L. Ray, of Fulton; Dr. U. S. Wright, of Fayette; Dr. I. T. Hall, of Potosi; Dr. J. L. Eaton, of Irondale; Dr. Wm. H. Crandell, of Birchtree; Dr. N. J. Petijohn, of Brookfield; Dr. W. L. Crawford, of Sedalia; Dr. A. C. Bernays, of St. Louis; and Dr. J. P. North, of Jefferson City. Georgia also will send twelve delegates; Iowa, eight; West Virginia, five, and a large number of States, three each.

The Indiana State Medical Society will hold its fifty-second annual session at South Bend, Ind., from May 15th to 17th inclusive. The following is the programme: May 15th: 1 p. m., meeting called to order by Dr. G. W. McCaskey, president, Fort Wayne; 8 to 12 p. m., entertainment of visitors by St. Joseph County Medical Society. May 16th: 8 a. m., morning session; 1 p. m., afternoon session; 8 p. m., evening session, address by Dr. G. W. McCaskey, Fort Wayne; address by Dr. John A. Wyeth, New York City; 10 p. m., reception. May 17th: 8 a. m., morning session; 1 p. m., afternoon session. The officers are: President, G. W. McCaskey, M. D., Fort Wayne; vice-president, A. M. Hayden, M. D., Evansville; secretary, F. C. Heath, M. D., Indianapolis; assistant secretary, J. B. Berteling, M. D., South Bend; treasurer, A. E. Bulson, M. D., Fort Wayne. Committee on Arrangements: Chairman, J. B. Berteling, M. D., South Bend; H. T. Montgomery, M. D., South Bend; C. A. Daugherty, M. D., South Bend; Chas. Stoltz, M. D., South Bend; C. C. Terry, M. D., South Bend. Reception Committee, St. Joseph County Medical Society: President, F. P. Eastman, M. D., South Bend; vice-president, G. W. Van Benschoten, M. D., South Bend; treasurer, C. M. Butterworth, M. D., South Bend; secretary, H. F. Mitchell, M. D., South Bend. The New Sheridan Hotel, the Hotel Johnson, and the Columbia Hotel offer special rates of \$1.50 a day. The Hotel Nickel is on the European plan.

In Memory of Dr. William H. Draper.—At a special meeting of the medical board of St. Luke's Hospital,

New York city, a memorial notice of the death of Dr. William H. Draper was adopted reciting the facts regarding his connection with the institution for the past forty-four years and concluding with the following eulogy: Dr. Draper possessed intellectual, social, and moral qualities that made him in many ways an ideal physician. He was a careful and thorough diagnostician. His sound judgment gave him the confidence of his patients and his professional brethren, while his kindness of heart and a peculiar charm of manner won him hosts of friends. His distinguished career will be remembered with pride by the profession which he adorned, but those who enjoyed the pleasure of a long friendship with him will always feel that the man himself was the chief attraction. The sterling principles of his character, his uprightness, his loyalty, and his loveliness were the qualities which made his friends love him even more than they admired his great ability as a scientific physician.

Obituary Notes.—Dr. James S. Carradine, of 45 West Twentieth Street, New York City, died on Tuesday, April 23d, at the age of sixty-two. Dr. Carradine was born at Yazoo, Mississippi, and graduated from the medical department of the University of Pennsylvania. He served as a surgeon in the Confederate Army throughout the civil war, after the close of which he engaged in the practice of his profession in New York city. He was a member of the New York State Medical Association and of the Medical Society of the County of New York.

Births, Marriages, and Deaths.

Born.

IRWIN.—In New York, on Sunday, April 28th, to Dr. and Mrs. S. Nelson Irwin, a son.

Married.

CONGDON—HALL.—In San Francisco, on Thursday, April 18th, Dr. C. E. Congdon and Miss Isabelle Hall.

CURRY—HAMILTON.—In Zanesville, Ohio, on Saturday, April 27th, Dr. Joseph James Curry, United States Army, and Miss Helen Hamilton.

DUKE—WALSH.—In Washington, on Thursday, April 18th, Mr. J. Clarence Duke and Miss Beatrice A. Walsh, daughter of Dr. James F. Walsh.

FINCKE—BROWN.—In Brooklyn, on Thursday, April 25th, Dr. Charles L. Fincke and Miss Mattie T. Brown.

KEENAN—MAGUIRE.—In San Francisco, on Tuesday, April 16th, Dr. Alexander S. Keenan and Miss Laura Maguire.

LAMBERT—GURNEY.—In New York, on Tuesday, April 23d, Dr. Walter Eyre Lambert and Miss Grace Gurney.

MESMER—HOFFMAN.—In Buffalo, on Tuesday, April 16th, Dr. John M. Mesmer and Miss Elizabeth Gray Hoffman.

ROBB—SMITH.—In St. Louis, on Thursday, April 18th, Dr. Malcolm Robb and Miss Teresa B. Smith.

WELLS—HORN.—In Washington, on Thursday, April 18th, Dr. S. J. Wells and Miss M. M. Horn.

Died.

BUCKLER.—In Baltimore, on Saturday, April 20th, Dr. Thomas H. Buckler.

CARRADINE.—In East Orange, N. J., on Tuesday, April 23d, Dr. James S. Carradine.

COGSWELL.—In Haverhill, Massachusetts, on Sunday, April 21st, Dr. George Cogswell, aged ninety-three years.

COX.—In Philadelphia, on Friday, April 19th, Dr. George W. Cox, in the sixty-first year of his age.

GRAHAM.—In Philadelphia, on Tuesday, April 23d, Dr. Percy M. Graham, in the forty-first year of his age.

INGLIS.—In Denver, on Tuesday, April 23d, Dr. Roy Inglis, of Jersey City.

LITTLE.—In Toronto, Canada, on Thursday, April 25th, Dr. T. H. Little, in the fortieth year of his age.

MORRIS.—In Birmingham, Alabama, on Tuesday, April 23d, Dr. Edward Watts Morris, in the thirty-sixth year of his age.

STEWART.—In Peoria, Illinois, on Friday, April 12th, Dr. James T. Stewart.

WOODBURN.—In Indianapolis, on Tuesday, April 23d, Dr. J. H. Woodburn, in the seventy-ninth year of his age.

Obituaries.

WILLIAM HENRY DRAPER, M. D., LL. D.,

NEW YORK.

DR. DRAPER died at his home, in New York, on Friday, April 25th, in the seventy-first year of his age. The immediate cause of his death was pneumonia. He was a native of Brattleboro, Vt., but came to New York early in life. He graduated from Columbia College in 1851, and from the College of Physicians and Surgeons in 1855. He subsequently served on the house staff of Bellevue Hospital. In conjunction with the late Dr. Henry B. Sands, he soon engaged in that subsidiary form of medical instruction known as "quizzing," and Sands and Draper's quiz speedily became renowned among the students of the college of Physicians and Surgeons. Soon after this period Dr. Draper was appointed a physician to the New York Hospital, where his clinical instruction was of the greatest value. In 1869 he was made clinical professor of diseases of the skin in the College of Physicians and Surgeons. In that capacity, too, he was exceedingly instructive to the students and to the many practitioners who attended his lectures. He held the chair for many years, and afterward was made professor of clinical medicine. In addition to his service in the New York Hospital, which he kept up until within a few years of his death, Dr. Draper was connected as a consulting physician with St. Luke's, Trinity, the Roosevelt, and the Presbyterian hospitals. He was at one time the president of the New York Academy of Medicine, and throughout the active period of his professional career he showed a lively interest in the affairs of that body.

Dr. Draper was not a frequent or a voluminous contributor to medical literature, but his writings, like his oral teaching, were marked by an uncommon nicety of diction and by a directness that made his meaning always unmistakable. His voice was pleasant to the ear, his presence was fine, and what he had to say was sure to prove instructive. He was one of the most refined men in the profession, besides being very handsome. His teaching of dermatology is doubtless the best remembered of his work. He was an excellent interpreter of Hebrew and his followers, while not neglectful of the St. Louis school; at the same time he was himself an acute observer. Much of his thought during the greater part of his professional life was given to the varied manifestations of gout, and especially to the dietetic treatment of that disease.

Dr. Draper was not a talkative man, but he was one of unusual amiability and very entertaining. He was proficient in music and exceptionally well informed in general literature and the fine arts. Although the demands of his practice were very great, he managed to devote a considerable portion of his time to Columbia University, of which he was a trustee, and to various other institutions with which he was connected in either a professional or an advisory capacity. His life counted for not a little in furthering the welfare of New York in an unobtrusive way, and the influence of his example will long be felt in the medical profession.

Pith of Current Literature.

Medical News, April 27, 1901.

The Study of Internal Medicine. By Dr. William Osler.—The author concerns himself with the question, "How shall a young man prepare himself to rise in the medical profession to a position in which his brethren lean upon his judgment and rely upon his decision?" He endeavors to answer it. In regard to going abroad, he believes that it is not necessary, though it is very helpful. The opportunities afforded in this country are not to be despised. After a few years, when the young physician needs a rest and a change, let him invest six hundred dollars in a summer semester in Germany, working quietly at one of the smaller universities and absorbing the spirit of patient investigation that is the genius of the German mind. "How shall the young man gain even his dry bread during the first few years of his professional career?" By picking up the crumbs that fall from the practice of the older men who can always put something in the hands of an able youngster, by fees from classes, journal work, private instruction, work from the schools, night work, surplus work in busy seasons, by taking poor or chronic patients that the older man cannot spare time to attend, by keeping office hours for the scanty summer practice of the wealthy physician who is taking his holiday; in short, by taking every sort of medical practice that comes to hand, for to see disease is the main thing, and a man must be willing to treat disease where he can find it, even though he barely ekes out a living while he is gaining his experience. At the end of twenty years, the author asserts, the man who has worked wisely and well should have a first-class reputation in the profession and a large circle of friends and patients. He will not have capital in the bank, but he will have interest-bearing funds in his brain pan. He may awake some day perhaps quite suddenly, to find that twenty years of quiet work, done for the love of it, has a very solid value.

The Relation of the Student of Medicine and the Recent Graduate to the Field of Surgery. By Dr. George Ryerson Fowler.—The author details the steps in the rise of the successful surgeon, and he demonstrates that, in the field of surgery, a full and complete knowledge of all the resources of the medical art is essential to the successful practice of this branch. The value of hospital work is enlarged upon, and the desirability of work abroad is impressed upon the aspirant. Sincerity and earnestness of purpose will place a man in the field of surgery, a worker. He may or may not become the originator of difficult or brilliant surgical procedures, but if he attains to good judgment, as based upon a cultivation of powers of observation and proper discrimination, combined with the experience which will certainly come to him, he will be trusted by his colleagues. When the profession trusts him, the public will have confidence in him, and when these have been reached he will have become a surgeon.

The Medical Man in the Navy. By Dr. W. K. Van Reypen.—The author, in an interesting article, gives information of a character that is often sought for. Upon passing the preliminary examinations, the applicant, who must be between twenty-one and thirty years of age, is appointed assistant surgeon, with the rank of lieutenant (junior grade). As a matter of fact, there are always some vacancies. The newly appointed assistant surgeon receives, at sea, \$1,650; on shore, \$1,402.50, besides

which there are allowances of \$288 per annum. The newly appointed surgeon formerly entered with the rank of ensign, and by regulation was placed in the junior officers' quarters. Now, entering with the higher rank, he becomes at once a senior officer, with all the privileges incident thereto, including quarters to himself. This makes possible the privacy and comforts so valuable and desirable in life while afloat, and places the medical officer from the commencement of his career in a position consonant with his age, habits of thought, and responsibilities.

The Municipal Health Department System, and more Especially in Reference to its Advantages and Disadvantages as an Opening for the Young Medical Graduate. By Dr. Arthur Guerard.—The author approves of the system, and though he admits that the obstacles in the way of appointment are undoubtedly great, they are not insuperable. In regard to the work itself, he believes that there is nothing which a young graduate can undertake at the present time that will give him a broader field of vision in his profession, especially at the beginning of his career, or more opportunity to do "the greatest good to the greatest number," while certainly benefiting himself, than the study of sanitary science and preventive medicine under the modern municipal health department system.

The Advantages in Examining for Life Insurance. By Dr. Brandreth Symonds.—This work is not for a lazy or careless man. It calls for a high grade of medical knowledge and it demands the strictest integrity. But to the honest, bright, up-to-date practitioner, examining for life insurance offers great inducements. A good examiner must keep himself constantly informed in the progress of medical science, and he should be constantly in touch with the practice of his profession. A physician should never give up his practice simply in order to make examinations for life insurance.

The Outlook for the Young Physician in State Hospital and Sanitarium Work. By Dr. Carlos F. MacDonald.—The author believes that the medical service in State hospitals for the insane, especially in the State of New York, offers to the young physician a most inviting field both for the clinical study of mental disease and in the matter of pecuniary compensation and allowances, which, in comparison with the pay and allowances of medical officers in other eleemosynary institutions, are on a very liberal scale. The salaries range from nine to twelve hundred dollars per annum and maintenance, for junior assistant physicians, up to four thousand five hundred dollars per annum, with maintenance for self and family, for medical superintendents.

The Medical Man in the United States Marine-Hospital Service.

Medical Record, April 27, 1901.

Experiences with Tracheotomy. By Dr. John Rogers, Jr.—In a series of seven cases reported by the author there are four laryngotomies and ten tracheotomies without a death that can be ascribed to the operation, though performed in great haste. Cocaine should always be used when the patient is controllable; but children or patients who cannot be kept quiet require chloroform, and in no instance, according to the author, does it cause trouble. Division of the cricoid, if the cannula has to be worn for any length of time, invariably leads to subsequent bad cicatricial contraction which can be cured only by prolonged intubation. Laryngotomy, ex-

cept for tumor, is absolutely useless. If the stenosis is not chronic, and there is hope of a speedy cure by a simple tracheotomy and the wearing of a cannula for a couple of weeks, and also if a careful dissection is possible, the low operation is to be preferred. But in chronic cases, in which the stenosis must afterward be overcome, and in cicatricial stenosis, the low operation is exceedingly troublesome, and the high operation is preferable.

Recurrent Vomiting of Nervous Origin. By Dr. Louis Fischer.—In a case reported by the author the patient is a female, fourteen years of age. The condition seems to improve under the following therapeutic measures: (1) Lavage, after which she improves for a week or more; (2) morphine or opium in small doses; (3) sodium bromide, ten to twenty grains, repeated every few hours; (4) hyoscyamine hydrochloride, one one-hundred-and-twentieth of a grain for a dose, three times a day. In addition, faradaization, massage, and cold baths, showers, diet, iron, and general restorative treatment, including hypophosphites and cod-liver oil, have been tried. Rich nitrogenous diet (concentrated foods), rest for the stomach, with ice locally, and an abdominal support (bandage), have been ordered.

Tobacco as a Factor in Glycosuria. By Dr. Heinrich Stern.—The author finds that tobacco may influence the pre-established pathological output of urinary glucose in the following ways: (1) By protracting the duration of transitory glycosuria, and by imparting to alimentary mellituria a certain degree of chronicity; (2) by increasing the quantity of dextrose in the twenty-four hours' urine, in the transitory as well as the chronic forms of glycosuria; (3) by transforming the lighter degrees of chronic glycosuria into the graver forms. These results he attributes, in great part, to the presence of carbon monoxide in the fumes of tobacco, it being a product of the imperfect combustion. He remarks that, as much less carbonic oxide originates from tobacco smoked in pipes, he has observed tobacco glycosuria only in smokers of cigars and never in those who consume tobacco in pipes exclusively. It is an established fact that, in chronic carbonic-oxide poisoning, glucose is very often found in the urine.

Pityriasis Versicolor of the Face. By Dr. William S. Gottheil.—The patient is a young colored man, and the points of interest about the case are the appearance of the lesions as circular, grayish-white discolorations upon a dark surface, instead of yellowish or reddish-brown stains upon a light one, and that they appeared upon the face only. The patient was rapidly cured by washing the affected area several times daily with 1:3,000 solution of bichloride in tincture of green soap.

An Extreme Case of Simple Anæmia. By Dr. Rolfe Floyd and William J. Gies, Ph. D.—This very interesting article embodies the results of a careful study of the case in question, and a comparison of the case with a typical case of pernicious anæmia. The authors conclude that, to obtain a satisfactory classification of the anæmias, it will be necessary, besides counting and studying the peripheral blood, (1) to understand the life history of the blood cells, which can be accomplished only through study of the physiology and pathology of the blood-making and blood-destroying organs; (2) to investigate more thoroughly the interrelations between the normal and diseased processes occurring in the blood and those occurring in the other body tissues; (3) carefully

to correlate the results of such studies with those obtained by clinical experience.

Albuminuric Retinitis in Pregnancy: Premature Labor; Death in Utero of Twin Child; Puerperal Convulsions; Hemiplegia; Acute Mania: Death. By Dr. Joseph N. Study.

Boston Medical and Surgical Journal, April 25, 1901.

Remarks on Anæsthesia—General, Local, and Spinal. By Dr. Maurice H. Richardson.—The author calls attention to the fact that we are apt to forget, in making comparisons, that the dangers of general anæsthesia have been demonstrated in almost countless cases. A danger which is regarded by many of us too great to justify the use of chloroform does not comprise, even in the most unfavorable statistics, more than one death in five hundred cases; in ether, a much smaller ratio. The author does not believe that spinal cocainization will present as small an immediate danger as the general anæsthesia of chloroform—a danger which he regards as prohibitory. When ether is given carefully there is no distressing anxiety as to the outcome, and the author feels that his patient is as safe as he can be.

Experience in Search of a Cure for Asthma in the Far Southwest, with Observations of the Comparative Value of Different Sections in Respiratory Diseases. By Dr. Robert Bell.—A few practical points in sending patients to the far southwest. Be careful to send them in the first stage of their disease. Second-stage and third-stage patients may have life prolonged, but rarely recover. They should spend the early months of their sojourn in resting and living as much as possible in the open air. If a patient is highly nervous, or liable to hæmorrhage, select a place of moderate altitude. It is important that the patient should remain in the West for many months after his cough has ceased, and until he has regained and held his weight.

Chorea during Pregnancy. By Dr. F. S. Sewell.—In regard to the frequency with which chorea complicates pregnancy, the author mentions that a study of the records of the Boston Lying-in Hospital shows that in eleven thousand cases there have been thirteen cases of chorea. Eleven of these cases were in primiparæ, who gave a history of previous attacks during childhood. One of the others was in a multipara in her third pregnancy, and she gave no history of previous attacks, either in childhood, or at the birth of her other children. The last case was in a secundipara, who had chorea in childhood but not in first pregnancy. In ten of the patients the movements entirely disappeared within a week of delivery, and in the other three, the movements were very slight at discharge.

Notes on X-light. By William Rollins.—The author believes that the most important discovery to be made in x-light tubes is to find how to keep the character of the light constant. Meanwhile, the best way to excite an x-light tube is to use surges of millions of volts and many horse power, each surge lasting for not more than a millionth of a second.

A Special Form of Phlegmon of the Neck. By Dr. F. P. Emerson.

Journal of the American Medical Association, April 27, 1901.

Notes on Adrenalin and Adrenalin Chloride. By Dr. E. Fletcher Ingals.—The author's experience bears out his own previous conclusions and those of other au-

thorities on the value of the suprarenal gland in diseases of the throat and nose.

Hypospadias. By Dr. C. H. Mayo.—The author proposes a combined operation for the relief of this condition, with these advantages: (1) A urethral tube of thin elastic skin nearly approaching mucous membrane, yet having no hair surface to occasion later complications; (2) a perineal drain for the bladder, with a self-retaining Jacob's female catheter; (3) a silkworm drain for the urethra; and (4), in being a method capable of application to the worst types of hypospadiac cases.

The Pollution of Streams and the Purification of Public Water Supplies. Comparative Efficacy of Slow Sand and Mechanical Filters. By Dr. George M. Kober.—The author has prepared a table showing the average number of deaths from typhoid fever in several American cities, before and after filtration. From this table it would seem that, while sand filters accomplish a reduction of 78.5 per cent. in the number of deaths from typhoid fever, the establishment and use of mechanical filters have coincided with a reduction of only 26 per cent. in the number of deaths from this cause.

Floating Kidneys in Children. By Dr. I. A. Abt.

Advances in Obstetrics during Last Half Century. By Dr. A. H. Halberstadt.—The author finds that, while medicine and surgery have prodigiously advanced and therapeutics has become almost revolutionized, obstetrics continues in the trend of a former half century. In regard to the use of anæsthetics, the author states that, fortunately, most physicians regard an anæsthetic as directly indicated in unnatural labors, and rarely attempt version or craniotomy without it; but unless some desperate emergency exists, a morbid apprehension of some mythical possibility seems to seize the mind and govern their action, and a humaneness, for which as physicians and surgeons they may be proverbial, deserts them in the very hour when the tenderest sympathy and promptest care should demand the consummation of a possible painless and happy conduct by that boon which, to a parturient, falls but little short of what may well be termed a special therapeutic indication.

When should Patients be Advised to Eat Everything? By Dr. Boardman Reed.—We should not do this until we have thoroughly cured their diseased digestive organs and freed them from the lithæmic condition. Unhygienic habits should be reformed in eating and drinking, as in work and play. Oxygenation must be made to bear its proper ratio to alimentation.

Poisoning from Auto-intoxication. By Dr. T. D. Crothers.—The points the author emphasizes are: 1. Alcohol in any form, taken into the body as a beverage, is not only a poison, but produces other poisons, and associated with other substances may develop toxins. Alcohol is also an anæsthetic and not a tonic or so-called stimulant. It increases the waste products of the body and diminishes the power of elimination. It also destroys the phagocytes of the blood, and thus removes and lessens the protective power of the blood cells. 2. Whenever alcohol is used continuously as a beverage, for its medicinal effects, favorable conditions and soils for the cultivation and growth of poisoned compounds are created. These may be neutralized by other conditions and not be apparent in the derangements of the functional activities which follow. Where disturbance and derangements of the nutrient and functional activities of the body are associated with the use of alcohol, their transient character and disappearance by the removal of spir-

its suggests the causes. 3. The functional and organic symptoms of derangement appearing in those who use spirits in moderation or excess, which quickly disappear by abstinence and eliminative measures, are clear indications of self-intoxications from this source. Obscure symptoms of the nervous system in persons who use spirits should always be examined in relation to the toxic origin from this source. Also grave nutrient disturbances should suggest the same cause with the same treatment. 4. The treatment of all such cases, in which alcohol is used in any form, should be by antiseptic and eliminative measures, and the supposition should always include the possibility of poison by chemical products formed in the body.

Proposed National Bureau of Materia Medica. By Dr. F. E. Stewart.

Hospital Cars for Railway Service. By Dr. W. L. Estes.

A Rule for Combining Crossed Cylinders. By Dr. Harry S. Pearse.

Philadelphia Medical Journal, April 27, 1901.

Scurvy in Infants. By Dr. Louis Starr.—The author disposes of the question of ætiology by his assertion that the direct cause of scurvy in infants is continued deprivation of fresh food. The different proprietary preparations of infants' foods the author regards as first in potency among the faulty foods. The scorbutic condition is produced gradually after weeks and months of improper feeding. The distinguishing features are, the development in infants from six months to two years old, after the prolonged use of unsuitable food, of extreme hyperæsthesia and immobility of the limbs; swelling of the thigh above the knee-joint and of the leg above the ankle joint; fusiform enlargement of the lower third of the shaft of the femur and tibia; deep purple discoloration, swelling and sponginess of, and hæmorrhage from, the gums surrounding erupted teeth; general cachexia and anæmia; and, finally—the test feature—rapid disappearance of symptoms and complete recovery following the adoption of an antiscorbutic diet, and—the negative symptom—non-involvement of the joints. The essential treatment is the employment of a food composed of cow's milk, cream, water, and milk sugar, properly proportioned to the age of the infant, and given, so far as the cream and milk are concerned, in the natural, fresh state, *i. e.*, not passed through the separator and not sterilized. The juice of fresh ripe fruit, orange juice especially, is a useful addition to the diet. Twenty-six illustrative cases accompany the article.

Notes on Leucæmia, with a Report of Three Cases. By Dr. Charles S. Jewett.—The author believes that, bearing in mind that the characteristic blood changes of leucæmia are qualitative rather than quantitative, it is possible in any well-marked case to determine from the blood examination alone, both the existence of the disease and its variety. In the earlier stages this result may not be obtainable, and certain well-developed cases show, during their progress, as a result of complications or of therapeutic measures, such marked remissions in the leucæmic peculiarities of the blood composition that an examination during one of these remissions would fail to show the true character of the disease. In such cases repeated blood examinations may be necessary in order to clear up the diagnosis. The author believes that many cases of leucæmia in this country are overlooked.

Observations and Tabulated Report of the Results of One Hundred and Fifty Operations for Appendicitis. By Dr. Leon Brinkman.—Operations were performed in the acute cases as follows: 4 within ten hours after onset; 11 after fifteen hours; 11 after twenty-four hours; 4 after thirty-six hours; 5 after forty-eight hours; 13 after three days; 3 after four days; 5 after five days; 1 on the sixth day; 2 on the seventh day; and 1 on the twelfth day. Of the chronic cases, 2 were operated on during an acute exacerbation, and 3 directly after the attack had subsided. The most common complications met with were: Perforation in 33 instances, localized abscesses in 35, abscess in the appendix in 4, and abscesses in the omentum in 1. Ten of the acute cases were followed by hernia and four by fæcal fistula.

Points Connected with the General Ætiology and Pathogenesis of Diabetes Mellitus. By Dr. Heinrich Stern.—The author asserts as a fact that, in the United States, at least, the mortality statistics afford us the most reliable method of obtaining certain general ætiological data of diabetes. In accordance with his belief the author has studied the mortality statistics of New York city, pertaining to diabetes mellitus, for a period of eleven years up to 1891, and in this article are given a few of the data and the conclusions derived therefrom.

Lancet, April 20, 1901.

Carcinomatous Stricture of the Duodenum. By Dr. H. D. Rolleston.—The author reports the case of a man, aged fifty years, who suffered from a carcinomatous stricture of the duodenum. Complaint was made of epigastric pain and vomiting. The vomitus was copious, more fluid being brought up than had been taken by mouth (gastrosuccorrhœa). After such copious vomiting the urine was suppressed. The vomitus contained bile, showing the obstruction to be below the biliary papilla in the duodenum. The urine contained much indol and creatinin. The patient gradually sank, and after developing pyæmia, died of exhaustion. The case presented the features of recurrent attacks of severe vomiting. The abdomen was never distended, so it was assumed that there was obstruction in the small intestine, but as no tumor could be felt at any time the diagnosis was not thought to be sufficiently assured to justify an exploratory operation. That the obstruction was not absolute was shown by the passage of fæces containing bile. At the autopsy there was found a tight stricture of the third part of the duodenum just where the mesentery crosses over it. Microscopically, the growth was a carcinoma with columnar cells. Primary carcinoma of the duodenum is much more localized than sarcoma and usually tends to produce an annular stricture. It is a disease of late middle or advanced life. The first part of the duodenum is rarely affected. The second part of the duodenum is that usually involved, while carcinoma of the third part is the least frequent of all the three varieties.

Autopsychorrhhythmia or Repetition Psychoneurosis. By Dr. C. H. Hughes.—Psychorrhhythmia is a tendency of the mind, more or less resistless, to repeat continually and nonvolitionally its once volitional actions even at inopportune time and place. It is a habit volitionally induced which has passed into a morbid automatic impulse associated with brain overstrain or excitation. The form of insanity to which autopsychorrhhythmia tends is that in which imperative conceptions predominate or have predominated in the initial stage of the mental disease. In aggravated form it is an imperative, resistless impulse to repetition of psychological impression in

the form of verbal expression. There may also be a tendency to imitative acts. The pathological lesion is evidently in the mind area of the brain cortex. It is a psychological and not purely psychomotor involvement, a psychical lesion shown in peculiarity of psychomotor expression.

Correspondence between Cholera and the Prevalence of Comma Bacteria in Well Waters of Gujarat during the Famine of 1900. By G. Lamb, M. B.—The author has investigated this subject, his results being as follows: Thirty-three well waters in fourteen different localities were examined. In eight of these localities comma-curved bacteria were found, while in the other six they were absent. In seven of the first-named eight localities, cases of cholera were still occurring daily. On the other hand, in all the six localities where no comma-curved bacteria were detected, there were no cases of cholera occurring at the time when the water samples were examined. The practical advantages to be derived from examinations of the water of any given locality are: 1. In a place vacated on account of cholera, the examination of the water may help to determine the date when it becomes safe to return to the place. 2. In a place where there are only a few sporadic cases of cholera a similar examination may give warning if a serious outbreak or recrudescence is threatening. 3. In a locality where cholera is epidemic the bacteriological examination of the water-supply may reveal those sources which are dangerous.

When to Operate in Perforative Peritonitis. By A. C. Roper, F. R. C. S.—In this article the author reviews the causes and symptoms of perforative peritonitis, and the indications for operation. These last are: (1) The condition of the patient—the pulse, the temperature, and the aspect; (2) the condition of the abdomen; and (3) the presence or absence of a swelling. A condition of profound shock often obtains at the beginning of these cases, during which any operative interference should be avoided. The patient has a better chance for recovery if first rallied with strychnine, brandy, and opium. Such a condition of shock should be the only cause of delay in operating upon a case of perforated gastric ulcer. Opium should be given to relieve the agonizing pain at the beginning of an attack, but if persisted with, usually obscure the diagnosis and increase the distention. Opium is better than morphine as it is less of a bowel paralyzer.

Recurring Attacks of Catalepsy Alternating with Violent Mental Excitement. By Dr. W. G. Stone.

On the Causation and Treatment of Profuse Epistaxis in People beyond Middle Age. By Dr. G. Coates.—The author reports an interesting series of five cases of profuse epistaxis not caused by a blow or injury, but coming on without any apparent cause in adults aged fifty years and upward. The attacks were sudden in their onset, and profuse, generally lasting from half an hour to an hour or more, and tending to recur for several days. In all, the sequence of events which led up to the epistaxis was essentially the same, namely: (a) Long-continued arterial pressure; (b) some sudden cardiac failure; (c) over-filling of the whole venous system, the weakened heart not being able sufficiently to empty the engorged veins against the high pressure in the arterial system due to contracted arterioles; (d) leakage from an over-filled vein. The most scientific treatment is, of course, to empty the over-filled veins; this can be done by relaxing the contracted arterioles and capillaries, for which nitroglycerin is quite effective. When the arteri-

oles are dilated and pervious, then comes the time to administer strychnine or strophanthus. In spite of everything, plugging may have to be resorted to in some cases. It should always be remembered that such profuse epistaxis as is here described is often a symptom of commencing valvular disease.

A Case of Recovery after Operation for Diffuse Peritonitis from Perforation of the Appendix. By C. A. Morton, F. R. C. S.—The author reports the case of a man, aged forty-four years, suffering from diffuse peritonitis, showing how dangerous a recurrent case of appendicular inflammation may be, and that severe peritoneal infection may be present with a pulse hardly raised above normal, a very slight rise of temperature, and a complete absence of vomiting and of those signs of general prostration which are so frequently associated with septic peritonitis.

The Open-air Treatment of Phthisis at Home. A Short History of a Case. By F. W. Bartlett, M. R. C. S.—The author reports the case of a woman, aged thirty-eight years, suffering from pulmonary tuberculosis. At the time that treatment began she had been ill for three or four years; there was well-marked consolidation and cavity formation at the apex of the left lung, and there was an evening rise of temperature. There were also signs of beginning disease of the right lung. The open-air treatment at home was decided upon, and a shepherd's van was placed in the garden of the patient's house. The side of the van facing south was removed, shutters for stormy weather were attached, and a small stove and flue placed in one corner. Treatment was commenced in winter (February) and the patient spent the whole of the time between breakfast and sunset in the van, either on a couch or in a chair, with the exception of half an hour for dinner in the middle of the day. When the weather was favorable, she took short walks. During the first three months one minim of creosote was taken three times a day, and occasionally an anodyne cough mixture was administered. Her condition began to improve within a week of her taking up this outdoor life. In the first seven weeks she gained seven pounds. Twelve months later the patient was plump and well-conditioned; cough and expectoration had almost disappeared; the physical signs of disease over the left lung had greatly abated, and the signs of commencing disease at the right apex disappeared, as had the tubercle bacilli from the sputum.

No. 6 General Hospital, Johannesburg. By Dr. A. Watson.

Clinical Notes on the Wounded in South Africa. By J. W. Smith, M. B.

The Princess Christian Hospital in South Africa. By G. V. Worthington, M. B.

Veld Sores. By Dr. A. Ogston.—The "veld sore" appears to be a disease peculiar to South Africa. It resembles epidermic vesication, but is not a vesicle. The epidermis is elevated into a semi-translucent swelling, often with ill-defined margins averaging about one-quarter of an inch in breadth. These margins are vesicular

only in appearance and do not exude serum when punctured. A small spot in the centre, however, soon forms a blister filled with clear fluid, which at once bursts, and bursts so soon that it is rarely seen entire. Where it gives way an ulcer is seen involving the true skin and increasing in extent as the margins go on spreading peripherally. Around the outermost margins is a halo of diffuse erythematous redness, never very intense and seldom causing inflammation of the lymphatic vessels and glands. The sores occur mostly on the hands and forearms, but also on the feet and legs. Their usual size is that of a shilling or less; they are often multiple. Suppuration is not a characteristic of the veld sore. The vesicular-looking margins yield no pus, and the open centre of the ulcer very little. Crusts from the serous discharge tend to form on the latter. A breach of the epidermis seems to be necessary for the origin of the disease. The fluid from the periphery contains enormous numbers of an organism, a micrococcus resembling the gonococcus in appearance; it is, of course, not one of the pyogenic organisms. No conveniences for cultural study of this *Micrococcus campaneus*, as the author calls it, were obtainable. He thinks it the cause of the disease, and that it is probably an inhabitant of the vegetation and soil of the veld. The cases were treated by clipping away the whole of the epidermis involved, and applying an antiseptic (carbolic) dressing.

Some Observations on Veld Sore. By W. H. Harland, M. R. C. S.—The author's description of the veld sore corresponds, in the main, to that given by Ogston in the preceding article. He states, however, that a certain amount of lymphangitis and enlargement of the epitrochlear and axillary glands almost invariably accompanies the sore. Constitutional symptoms, as elevation of temperature, headache, and constipation, are often present. The treatment is simple; incisions are made in the papule or pustule, if necessary, and in most cases the frequent application of boric or carbolic fomentations, with rest of the affected limb, together with the administration of a mild aperient, usually causes the sore to lose its painful character, gives it a healthy appearance, and removes the attendant adenolymphangitis and constitutional symptoms. A feature of the lesion is the scarring which ensues, the scar remaining smooth and bluish for a considerable time after healing. No microscopical or bacteriological examinations of the fluid from the sores were made.

Report on 295 Cases of Enteric Fever, General Hospital, Tin Town, Ladysmith. By Dr. D. Melville.—**The Rose Rash.** In about 40 per cent. of cases no rash was found, and in about 20 per cent. the rose spots were found thickly scattered over the trunk and the extremities, while in the remaining 40 per cent. the usual distribution was followed. The cases in which the thick rash was found all seemed to come from one locality. The presence, absence, or excess of the eruption seemed to have no bearing on the severity of the attack.

Diarrhœa. Only 5 cases had any diarrhœa, and, in these, lead and opium pills acted like a charm. Constipation was constant and hard to deal with.

Cerebral Symptoms. As a rule the delirium was of the rambling or muttering type, giving rise to no anxiety. In 2 cases there was violent mania, one case ending fatally.

General Symptoms. These were all of the usual character associated with enteric fever.

Inoculation. Of the 295 cases, 30 were inoculated, the remaining 265 being unprotected. The uninoculated

cases compare very favorably with the inoculated. The complications were more numerous, the duration of the fever longer, and the death rate higher in the inoculated. The death rate of the inoculated was 6.67 per cent.; of the uninoculated 1.89 per cent., giving a total mortality of 2.38 per cent.

Hæmorrhage. This occurred in 17 cases (5.77 per cent.), 16 being in uninoculated cases. In several cases the loss of blood was severe.

Péritonitis. Perforation, which occurred in 3 cases, all of which terminated fatally, was the cause of death in 43 per cent. of fatal cases. In each case it was due to errors of diet.

Pneumonia. This complication became very common in the month of June. There were 11 cases in all, one of which ended fatally.

Thrombosis. This occurred in 5 cases, or 7.4 per cent. of complications. Embolism did not result in any instance.

Relapse. Relapse occurred in 23 cases. In no instance was there a second relapse, and all the patients made satisfactory recoveries.

Malarial Type. There were 5 of these cases, all of which quickly subsided on the administration of quinine.

"Typhoid Toes." There was 1 instance of this curious condition; the history of the case is given in full.

The low death rate in these cases is attributed to the use of carbolic acid internally and to sponging, together with excellent nursing.

Enteric Fever in South Africa: Effective Sterilization of Excreta. By Major H. A. Cummins, R. A. M. C.—The author reports the results of some bacteriological tests of the efficiency of disinfecting typhoid excreta, etc., by boiling in a large cauldron with crude carbolic acid. The experiments show that many bacteria survive for half a minute, while after one minute only one species remained. At two minutes all forms of life had become extinct.

Venesection in the Treatment of Gunshot Wounds of the Chest. By Captain F. J. W. Porter, R. A. M. C.—The author reports the case of a man, shot through the right chest, on whom he performed venesection, drawing off about ten ounces of dark blood from the median basilic vein; the patient's condition immediately improved and he made an uninterrupted recovery. The author thinks the patient would have died but for the venesection. His heart was unable to drive the blood through the undamaged lung, and was relieved by the reduction of the volume of blood in circulation.

Presse médicale, April 6, 1901.

Tuberculosis of the Kidney. By M. A. Brault.

Blastomycetes in Human Pathology.—M. F. Curtis takes issue with M. Wlaeff as to the possibility of producing epithelial tumors, in the histological sense, by means of the *Saccharomyces tumefaciens*. He has never found this blastomycetes in a non-ulcerating cancer. He maintains that it is impossible to produce an anticancerous therapeutic serum when the ætiologic factors are unknown.

Anomalous Forms of Paludism.—M. A. Billet says paludism is a protean disease. It shows normally, in the absence of an epidemic, the intermittent type of fever (quotidian, tertian, or quartan), but in times of epidemics, it most often appears as an irregular fever, remittent or continuous, with unusual symptoms, and it speedily brings about paludic cachexia. The hæmato-

logical examination is then the only certain guide to a correct diagnosis. The triple hæmatological characteristics of malaria are: (1) The constant presence of the hæmatozoön of Laveran; (2) the appearance of dark pigment, especially localized in the large uninuclear leucocytes; (3) a more or less pronounced uninucleosis in the leucocytes.

April 10, 1901.

Variable Physical Signs in Mitral Stenosis.—M. Ernest Barié says that the physical signs of mitral stenosis vary with the nature and extent of the anatomical lesions and with the stage of the disease. He analyzes the sounds of the heart in this chart:

Physical Signs.	First Degree of Mitral Stenosis.	Second Degree of Mitral Stenosis.	Third Degree of Mitral Stenosis.
	Snapping at opening of mitral valve.	None.	Very frequent.
Diastolic thrill.	{ Deep tone. Harsh timbre.	{ High pitch. Higher timbre. }	None.
First sound.	Striking.	Hard.	None.
Second sound.	Reduplication at aortic recession.	Accentuation of second pulmonary sound.	Reduplication at pulmonary recession.

Progrès médical, April 13, 1901.

Organic Sera in Therapeutics.—M. Edmond Vidal reviews the work done with organic sera developed in laboratories, inoculated into animals, and then tried upon human beings. He says that, with the exception of diphtheria antitoxine, no serum has yet shown results which would permit an extension of their use upon man. The so-called antitoxic sera act upon neither the germ nor upon the toxine developed by it, but upon the cells of the organism which carry on the fight against the bacterial enemy. The sera of immunized animals have therefore not a specific action, but a tonic influence which is exerted generally throughout the body. The therapeutic value of these sera has therefore not yet been definitely determined.

Gazette hebdomadaire de médecine et de chirurgie, April 7 and 11, 1901.

Treatment of Fractures of the Leg. By M. Du-jarier.—A clinical lecture.

Local and Circulatory Leucocytic Reaction in a Case of Grave Icterus.—M. Paul Caziot says that in a case of grave icterus, with acute hypertrophy of the liver, he found the hyperleucocytosis, both locally and in the circulation, quantitatively equal. Qualitatively, after the sixth day, a circulating uninucleosis might be demonstrated, while at the moment of death this had changed to a marked multinucleosis.

Wiener klinische Rundschau, April 14, 1901.

Some Phenomena of Hereditary Syphilis.—Professor J. Neumann says that, in his experience, children born of luetic parents, who did not show at birth or within the usual time, evidences of syphilis, have remained free from all evidences of the disease later. He regards it as unproved that grandchildren can show luetic disease from grandparents, as the chances of acquired syphilis in these cases can never be excluded; further, these cases have never presented in adult age those forms of syphilitic disease which are recognized as hereditary.

Hæmorrhage after Tonsillar Operations.—Professor Seifert reports two cases in which the bleeding was completely and promptly checked by tamponing the cavities. Properly carried out, he regards this as the safest method

of treatment, so that operative methods, such as circular suturing of the tonsils or ligature of the external carotid, are not necessary.

Acute Cocaine Intoxication. By Dr. Ernst Barth.

Centralblatt für Gynäkologie, April 6, 1901.

Four Cæsarean Sections with Horizontal Incision of the Fundus.—Dr. L. Heidenhain reports these cases. The horizontal incision of the fundus allowed of easy extraction of the child, and uterine contraction was excellent. The suturing was done with thin silk.

Treatment of Retroflexions.—Dr. A. Schücking describes his method of performing vaginal fixation. He scarifies the angle of anteflexion—artificially produced—passes a ligature through the broad ligament of one side close to the insertion of the round ligament, behind the uterus, and out through the other broad ligament. The ligature is left in place for ten days.

Centralblatt für innere Medicin, April 6, 1901.

Guaiaicol Treatment of Acute Gonorrhœal Epididymitis.—Dr. Berthold Goldberg has been much impressed with the analgetic effects of guaiaicol in the treatment of this condition. He prepares an ointment as follows:

R Guaiaicol. 5 parts;
 Lanolin, } of each. 10 "
 Resorbin, }

After a sitz-bath, the salve is applied to the painful parts, which are then covered over with linen, then with absorbent cotton and rubber tissue. A suspensory is worn over this dressing. The patient is instructed to take from forty-five to sixty grains of salol a day. The general condition, the pain and the swelling markedly improve in a short time. No pulmonary or cardiac impairment has been noted.

April 13, 1901.

Demonstration of Mercury in the Urine.—Dr. Bruno Bardach reports a delicate and accurate test, too complicated to be here described.

Centralblatt für Chirurgie, April 6 and 13, 1901.

Treatment of Irreducible Maxillary Dislocations. By Dr. Kramer.

Absorbable Intestinal Button of Magnesia.—Dr. V. Chlumsky reports the invention of a button of magnesia which he has found to be absorbed in from eight to ten days. It is easily and quickly applied.

Wiener klinische Wochenschrift, April 4, 1901.

Ætiologic-bacteriologic Diagnosis.—Professor E. Neusser speaks of the great importance of bacteriological diagnosis, its influence upon prognosis, and the scientific dignity it lends to internal medicine by its aid.

Botryomycosis in Man.—Dr. R. v. Baracz has found, in a case of botryomycosis of the finger, not only the *Botryomyces*, but also the *Streptococcus* and the *Staphylococcus albus* and *flavus*. He therefore differs with Poncet and Dor, who assert that the disease is caused only by the fungus *Botryomyces*. The author thinks the condition should be named polypoid fibroma myxomatodes.

Intestinal Hæmorrhage after Reposition of Incarcerated Hernia. By Dr. Josef Preindlsberger.

Wiener medicinische Blätter, April 4, 1901.

Treatment of Pernicious Anæmia (conclusion).—Dr. Alfred Stengel says that the mere administration of arsenic and bone-marrow are not sufficient in these cases. Massage must be employed to stimulate the circulation. Horizontal rest in bed, which makes least demands upon the heart, is also to be encouraged. Rectal infusions of salt water are recommended to stimulate peristalsis and to improve the circulation, and it may be advisable in some cases to administer the salt water subcutaneously or intravenously. The cause of the disease must be attacked when possible.

Drug Treatment of Nervousness. By Dr. H. Siegel.

Münchener medicinische Wochenschrift, April 2, 1901.

Version and Immediate Extraction in Contracted Pelves.—Dr. Walter Albert reviews the results achieved in sixty cases, unselected, occurring in the Dresden clinic in which, in cases of contracted pelvis, version followed by immediate extraction was performed. The mothers ran an uneventful course in 93.3 per cent. of the cases, and 81.3 per cent. of the children were dismissed living. The results are far better than when version is performed and a waiting policy is pursued, or when high-forceps operation is done.

Biological Proof of the Presence of Human Blood. By Dr. A. Dieudonné.

Localized Stasis in Cardiac Disease.—Dr. O. Rosenbach has found experimentally that iodine and its salts are rapidly absorbed, and in large quantities, by transudations, while quite the reverse is true of exudates. He regards this as a valuable "functional diagnostic" measure in distinguishing between the two.

Diseases of Chronic-acid Workers. By Dr. F. Hermann.

Multiple Fat Necrosis. By Dr. Paul Ostermaier.—A clinical article.

Aneurysm of the Ascending Aorta Treated by Gelatin-injection.—Dr. Karl Barth reports such a case in which the dyspnoëic symptoms, the vertigo, and the pain in the chest, back, and arm, became markedly diminished, and the tumor in the right infraclavicular region became much smaller and harder. The difference in the radial pulses also became less marked. He thinks the method has many decided objections.

Riforma medica, March 8, 1901.

Urea and Metabolism in Children. By Dr. Albano Bonfa.—The amount of urea per kilogramme eliminated by children diminishes with age, but always remains larger than the corresponding amount in adults. The total daily elimination of urea remains practically constant from the second to the tenth year, and varies between 8.5 and 10.5 grammes; while, in the adult, it is 21.5 grammes. The average percentage of urea in the urine is lower in children. The proportionate amount of urea is greatest in the first years of life, and always exceeds more than twice the proportional amount in adults. The activity of nitrogenous metabolism in children, as expressed in figures denoting the quantity of urea per kilogramme of body-weight, varies inversely as the weight of the child. The weight of a child varies as the amount of nitrogen consumed in metabolism. In children affected with gastro-enteritis the amount of nitrogen consumed is lower than in normal children. In fever there is an

increase in the nitrogenous metabolism and the amount of urea is increased.

March 9 and 10, 1901.

A Case of Multiple Myeloma (Kahler's Disease?). By Dr. T. Venturi.—Bozzolo gave the name Kahler's disease to a condition in which multiple myelosarcomata in the bones were associated with an abundant amount of albumoses in the urine. Kahler first described a case of this kind in the *Prager medicinische Wochenschrift*, in 1889. The author reports a case of the same kind in a man aged thirty-one years. The sarcomata invaded the spinal cord, and the patient died within three months. The autopsy showed multiple myelogenous sarcomata in the bones of the trunk and cranium, as well as secondary deposits in the cord and in the lungs.

Gazzetta degli ospedali e delle cliniche, February 10, 1901.

On Acute Rheumatic Polyarthrititis. By Dr. E. Maragliano.—The author presents the histories of three patients with acute rheumatic polyarthrititis and concludes that the joint affections in these instances were due to the invasion of the common germs of suppuration. He discusses the proposition of Singer, of Vienna, who, in 1898, formulated this statement of the aetiology of polyarthrititis: "Acute rheumatic polyarthrititis is a special variety of pyogenic infection." The author admits that there is a form of polyarthrititis caused by pyogenic germs, but this affection has a clinical picture peculiar to itself. Researches conducted in the author's clinic by Dagnino, an American, showed the presence of a special type of staphylococci in the exudates and in the blood of patients with arthrititis. Injected into animals, pure cultures of this germ caused arthrititis, pericarditis, and endocarditis.

On Flaiani's Disease. By Dr. Cesare Regolo Rabaioli.—Flaiani, a Roman physician, described exophthalmic goitre in 1800. The author says that this affection deservedly is known by the name of the Italian observer. (Flaiani's name is very rarely associated with exophthalmic goitre, the names of Graves and Basedow, as a rule, being used in its designation.) The author reports a case of this disease in which he used iodides and electricity with fair results. He condemns the use of thyroid gland extract, which has been given on the theory of hypothyroidization, and studies the toxicity of the urine in these patients by a series of experiments on animals.

A Contribution to the Study of the Pathogenesis of Delirium in Infectious Diseases. By Dr. Ugo Arturo Betti.

A Method of Treatment for Cases of Acute Rheumatic Polyarthrititis. By Dr. Francesco Zagato.—In a case of articular rheumatism with effusion in the knee-joint, the author aspirated the fluid under antiseptic precautions, removing about sixty cubic centimetres, and injected a two-and-one-half-per-cent. carbolic-acid solution into the articular cavity. The fluid did not return, and the recovery was very rapid.

Electrotherapy in Exophthalmic Goitre. By Dr. Angelo Lamari.—Galvanization of the vagus and the sympathetic was employed, the anode being placed upon

the inner margin of the sternocleidomastoid muscle, the cathode on the sternum. Two or three milliampères were used for from four to eight minutes twice daily. After the fifth sitting a mild faradaization of the thyroid gland was added. The patient had forty applications of electricity. After thirty sittings the symptoms of exophthalmic goitre were very markedly improved, and they disappeared completely at the end of the treatment.

Vratch, March 3 (March 15, New Style), 1901.

Five Hundred Operations on Cataracts. By Dr. S. N. Korginevsky.—The author's results were as follows: In 348 cases, good vision; in 61 cases, fair visual capacity; in 17 cases, weak vision; in 25 cases, no vision. In 22 cases the acuteness of vision had not been noted.

A Case of Recurring Extra-uterine Pregnancy. By Dr. D. D. Sandberg-Debele.—Recurring extra-uterine pregnancy is very rare, and Kuester found only two cases in which a second extra-uterine pregnancy was observed among 107 cases of this form of gestation. The author observed a case in which there were two successive extra-uterine pregnancies, both with rupture, in a woman aged thirty-four years. This was the only case of its kind among 134 cases of extra-uterine pregnancy collected during a period of ten years. Kuester stated that laparotomy and the removal of the ruptured tube were preventives against a recurrence of the extra-uterine pregnancy. This is not always the case, as the author shows, for an extra-uterine pregnancy almost never recurs on the same side. Some French authors have suggested the removal of the appendages on both sides on this account, but this proposition has not met with favor.

A Case of Diabetes Mellitus in a Nursling. By Dr. N. A. Orloff.—The author states that this case is the seventh on record in which sugar was found in the urine of a nursing baby. Of these seven cases the present is nearest to genuine diabetes mellitus. It is difficult to decide whether, in the other cases of glycosuria in infants, there was really diabetes mellitus or only an abnormally large quantity of lactose excreted by the kidney. The infant whose case the author reports was four months old. His urine showed distinctly the presence of sugar. In addition, he had an umbilical hernia, and a crop of furuncles. He lost rapidly in weight and nursed poorly. The child died on the twelfth day of the disease. The autopsy showed an enlarged third ventricle filled with serous fluid, bronchopneumonia, acute enteritis, and oedema of the meninges.

A Case of Diabetes in a Boy Aged Three and a Half Years. By Dr. V. I. Noskoff.

Poisoning by Cream Tarts in Kharkoff (continued). By Dr. P. N. Laschenkoff.—The author gives the results of an examination of certain cream tarts which had been bought at a bakery in Kharkoff and had caused poisonous symptoms in a number of people. A bacteriologic examination of the layer of cream covering these tarts revealed the presence of *Staphylococcus pyogenes aureus*. Examinations of the same form of tarts prepared in the same bakery at another time, showed that there were no staphylococci in the cream. The author's conclusion is that the cause of the poisoning by these cream tarts was the presence of germs of suppuration which developed toxins in the intestinal tract and thus gave rise to enteric disturbances. (*To be continued.*)

New Inventions, etc.

AN IMPROVED FORM OF APPARATUS FOR THE

IRRIGATION TREATMENT OF GONORRHŒA.

By HENRY P. HAMMOND, A. M., M. D.,

SLINGERLAND, N. Y.

THIS apparatus is the result of an attempt to devise a more simple and cleanly irrigator, and one more handy and reliable in manipulation, than those in common use.

of an inch wide, cut half way through. A curve in the bottom of the loop fits the curve of the inside of the tube. Rubber tubing from the reservoir passes under this loop, which compresses it, thus shutting off the flow. The tubing carries the usual glass tip. The instrument fits naturally to the hand and responds instantly to pressure on the spring, thus giving perfect control of the flow.

The irrigating basin is triangular, one corner being rounded to fit the curve of the legs when the knees are spread. This corner is about nine inches high and has a hole three inches from the top, to admit the penis. At the other two corners the basin is four inches deep. The rounded corner thus acts as a shield to protect the patient from any spattering, the fluid being caught in the basin below. It is very easily cleaned and is much more convenient than rubber aprons or towels.

A percolator is used as a reservoir, and is supported by an incomplete metal band that has a lug opposite its opening, into which is firmly fastened at right angles a brass tube eighteen inches long. This slips over a rod four feet long, fastened two inches from a wall by two brackets at its ends. The rod has a longitudinal slit behind, in which a pin in the tube runs, preventing its turning on the rod. The percolator being filled and placed in the ring while the tube is at the bottom of the rod, the tube is grasped by its lower end and the whole slid up the tube, where it is held by a catch in the rod resembling an umbrella catch. The reservoir may thus be raised the length of the tube above one's reach.

This apparatus does not differ in its use from those commonly employed, and no description, therefore, need be given.

AN INSTRUMENT TO ENTER DEEP-SEATED PUS CAVITIES.

By FREDERIC GRIFFITH, M. D.,

NEW YORK,

SURGEON BELLEVUE DISPENSARY.

IN the technique of operations for opening collections of pus in the lungs, the liver, or the kidneys, there is a point at which surgeons hesitate. It is the common practice to locate deep-seated fluid collections with a hollow needle and syringe connected by small rubber tubing containing a glass joint, that the operator may know at once when he has reached fluid.

To enable the surgeon to open the cavity without fear of losing the lead of the needle, I have devised a grooved director with an eyed tip.

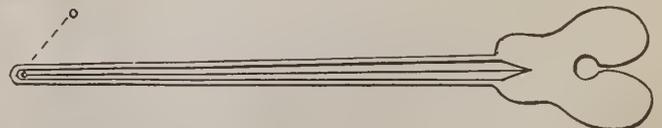

The instrument is used by passing the point of the exploring needle through the eye (O).

When the fluid cavity is found, with the needle as a guide, the director can be at once entered. Withdrawing the needle, the opening may be readily enlarged by passing a knife-

Apparatus for the Irrigation Treatment of Gonorrhœa.

Attention is especially directed to the shield and cut. The form devised consists of a four-inch metal shield at the end of a tube five inches long and one-half inch in diameter. A stiff spring, four inches long, is fastened at one end to a lug attached to the tube near the shield. Near the other end carries a loop of stiff wire, which encircles the tube. The tube at this point has a transverse slit, one-eighth

O is a hole from $\frac{3}{32}$ d to $\frac{1}{16}$ th of an inch in diameter, made in the bulge of the tip.

point, scissors, or forceps, along the groove of the instrument. A probe may be also used as a guide for the instrument.

805 MADISON AVENUE.

Proceedings of Societies.

NEW YORK OBSTETRICAL SOCIETY.

Meeting of March 12, 1901.

The President, Dr. H. J. BOLDT, in the Chair.

Sarcoma of the Ovary.—Dr. BACHE MCE. EMMET presented a specimen. The tumor had been removed two weeks before from a multipara, forty-nine years old. A brother of hers had had cancer in the abdomen, and a sister had had a tumor of the lower abdomen. Within the last three or four years the mass had grown until it was of the size of a football. It was attached by its own ligament, and had a few thread-like adhesions. There was no derangement of the general health, and the woman had not suffered. The tumor proved to be of the round-celled variety. As the growth was essentially local, and the attachment so small, the speaker felt like encouraging the patient to feel no apprehension. He was aware, however, of the fact that there might be a return of the malignancy in a few years.

Dr. BRETTAUER remarked that he had seen a case several years before in which he found and removed a tumor of about half the size of the one presented, of the same variety. At the time of operation the patient complained of a hacking cough, and a diagnosis was made of metastasis. The patient recovered from the operation, but died three months later, apparently from the pressure of a large metastatic growth within the chest.

Dr. VINEBERG could recall two cases of spindle-celled sarcoma in which he had operated—one two, the other three, years before. Both patients were now in good health. Last summer he had operated upon a patient, and the tumor had proved to be a round-celled sarcoma. It was now more than nine months since the operation, and as yet there had been no recurrence.

The CHAIRMAN said that one of the patients whose cases he had reported had died shortly after the operation, and that the second had a recurrence in the abdominal wall which he had operated upon a year later.

Dr. WALDO said that the last patient referred to by the chairman was alive and well two years after, without recurrence. He had operated in a case several years before, and during the past year he had opened the patient's abdomen again, but had found the growth too extensive to remove.

Ectopic Gestation.—Dr. GRANDIN presented a specimen removed from a patient twenty-three years old, who had had two children, the latter two years before. She menstruated every four weeks, the flow lasting from seven to ten days. She menstruated last on February 15th, the flow lasting twelve days. On March 1st she again began to flow and continued to do so. There were no colicky pains or any data to suggest pregnancy. There was a mass behind and to the left of the uterus. Under ether anæsthesia the uterus was everted. There was no enlargement. A posterior vaginal section gave exit to blood and clots. An abdominal section was done for the removal of the ruptured left tube. There was almost a quart of clots and blood in the peritoneal cavity.

Carcinoma of the Intestine.—Dr. WELLS presented a specimen. The history was as follows: A woman, thirty-nine years old, noticed a small swelling in her abdomen a year before, since which time it had increased in size, and the patient had had progressive emaciation and loss of strength. For a week previous to February 14th she had suffered from continuous vomiting. There was

at this time a slightly nodular movable tumor of the size of a large orange occupying the lower right quadrant of the abdomen. An operation was considered to be advisable on account of the persistent vomiting, and on the 16th the abdomen was opened and the tumor, a carcinoma at the cæcum, near the ileocæcal valve, was removed, together with nine inches of large and small intestine, glands, and mesentery. After the operation there was no vomiting, whereas before the operation the patient had vomited everything that was introduced into the stomach. When the patient was taken off the operating-table the pulse was 120; the next day it dropped to 94, since which time it had been normal. When the patient entered the hospital her temperature was 100° F.; on the second day after the operation it was 101.8° F.; then it fell to 99° F. and was normal, and remained so, after the fifth day. The after-treatment had been by hot normal saline solution, a pint being given by the rectum every four hours, and a fortieth of a grain of strychnine hypodermically every four hours. As there was no vomiting, or nausea, or distention, she was allowed after the first day one or two ounces of beef juice every two or three hours. On the 18th she expelled gas and a little fecal matter. On the morning of the 19th she had a motion of over a quart of fecal matter and, later in the day, one of twenty ounces more. Since that time there had been daily movements of the bowels.

The resection of the cæcum and small intestine was done with the aid of O'Hara's forceps, so easily and so quickly and with after-results so pleasing, that the speaker wished to present the forceps to the attention of the society. There were two straight forceps, made light but strong; one was placed vertically on the intestine at a point where it was intended to make the section, the tips being carried exactly down to the mesenteric border; a second instrument was placed in the same manner at the second point of section; the gut was then divided close to either forceps and removed. The two instruments were brought together and held by a small clamp. This held the intestinal ends in apposition so that the suturing could be done accurately, easily, and quickly. Little handling of the gut was necessary, and there need be no contamination of the peritoneal surface by the intestinal contents. The method employed with these forceps represented a distinct advance in the technique of resection of the intestine. The speaker had used the Murphy button and had operated by other methods, but considered this to be, if not the quickest, the safest and simplest.

Dr. EMMET said that he had had a case similar to that reported almost a year before. He removed the carcinomatous mass and did an anastomosis by the Maunsell method, which he then described.

The Prevention of Postoperative Adhesions of the Peritonæum.—Dr. GEORGE G. WARD, JR., in a paper thus entitled, remarked that one who came into contact with patients after they had been subjected to peritoneal operations must surely be impressed with the fact that we had still much to learn before we could invade the peritoneal cavity without leaving that delicate membrane in a crippled condition in a large percentage of cases, as was shown by continued pain, constipation, and in some cases such bands of adhesion that a subsequent operation was necessary. He called attention to the fact that more was required for the welfare of the patient than simply to be able to open the abdomen, remove an organ or growth, and suture the wound without loss of life from hæmorrhage or sepsis.

It was known that adhesions were frequently found even in simple, uncomplicated cases. Thomson, after careful experiments, had found that omental and intestinal adhesions followed perfectly aseptic coeliotomies, and that parietal adhesions occurred when the abdominal wound healed by first intention. The evil results of the formation of adhesions varied from slight symptoms of no importance to the most fatal of postoperative sequelæ, intestinal obstruction. The danger of this last complication alone would render the prevention of the formation of adhesions of the utmost importance, especially as the condition was not a rare one, as all abdominal surgeons would testify. The proportion of deaths from this cause was between one and two per cent. One was apt to infer that the danger of intestinal obstruction was imminent only during the period of convalescence immediately following the operation, but, unfortunately, there were many cases on record in which the band had caused obstruction months or even years afterward. Then, again, there were cases of obstruction in which the diagnosis of "peritonitis" or "intractable vomiting" was made.

It was a well-observed fact that obstruction rarely occurred except where the loop of intestines had become fixed by adhesions in an abnormal position, the normal relations of the coils having been disturbed by the operation's interference. When obstruction under these circumstances did not occur, severe pain might result, requiring a second laparotomy for its relief.

The amount of pain from an adhesion might be out of all proportion to its size and strength, and frequently patients were treated for disturbances of various organs, the true cause being peritoneal adhesion. Chronic constipation was another annoying sequel, and in a form which admitted of no relief by correction of habits, as the mobility of the bowels was prevented by adhesions. The ætiology of the condition must first be considered, in order that treatment looking toward prevention might be studied. Adhesions between serous surfaces took place by the exudation of plastic lymph which acted as a cement substance, and the production of it had been excited by some disturbance of the normal condition of the membranes.

Adhesions between two raw surfaces, or between a raw surface and a serous surface, were brought about by the natural process of the repair of tissue, there being a cell proliferation from the endothelial and the connective-tissue cells, with the formation of a network of new blood-vessels arising from each of the coaptated granulating surfaces. These adhesions formed rapidly in the case of peritoneal surfaces, quite firm bands being formed in from six to twelve hours. As far back as in 1840 Gross had found that in dogs the intestines could become extremely adherent in a few hours.

Some investigators maintained that adhesions were produced by infection in all cases, while other observers asserted that adhesions could come about without infection, at least experimentally. From a series of experiments Walthard had concluded that long-continued contact with air so damaged the serosa that the superficial layer of cells died, and that, if two serous surfaces subjected to this exposure were in contact for a long time, adhesions formed between them, and, if they were not in contact for a long time, there occurred only a spongy exudation.

As to the way in which the air acted, Walthard's conclusion seemed justifiable, that the damaging influence of the air did not depend only upon its carrying infection and dust, but also upon the fact that air in a state of dry-

ness caused necrosis of the superficial layer of serous cells by cooling, with resultant contraction of the blood-vessels and diminished nutrition. The same author believed that after long contact with air the resisting power of the peritonæum was so diminished that the number of microscopic organisms necessary to bring about a fatal peritonitis was greatly reduced.

Walthard's deductions were, so far as possible, proved clinically in a series of one hundred and forty-six laparotomies for various causes. The serosa at the site of operation was kept moist with gauze wet in hot saline solution. No wiping or drying out of the cavity was allowed, and in no case was there sepsis or pseudo-ileus. Flatulence disappeared on the first or second day, while, when dry asepsis was used, flatulence lasted until the fourth or fifth day. The practical inference from his observations would be that dry asepsis and a dry toilet of the abdominal cavity should be abandoned, and that moist asepsis and, so far as possible, protection of the peritonæum from air contact should be practised.

Causes of adhesion might, then, be divided into two classes, namely, that of sepsis and that of traumatism. Sepsis might be virulent or mild. In the first instance, there was the adhesion formed as a result of general peritonitis with lymph and fibrous exudation. If mild, it might be in circumscribed areas, only sufficient to produce a localized inflammation with a plastic exudate. Likewise in traumatism, there might be severe and mild types. In the former the peritonæum had been stripped off or destroyed, while in the latter the superficial layer of cells only had been destroyed. This necrosis of the endothelial cells might be caused by excessive manipulation, chemical irritation from the use of antiseptic solutions in the abdominal cavity, or desiccation from dry-air contact, cold, and prolonged exposure. We might lay down the statement that the formation of peritoneal adhesions after operation was directly proportionate to the amount of sepsis, traumatism, dry-air contact, loss of heat, and raw surface present.

The fact that denuded surface and pedicle stumps were early recognized as one of the most frequent causes of intestinal obstruction from adhesion had led to many suggestions as to the prevention of this complication. Martin had advocated brushing over denuded areas and stumps with sterilized olive oil just before closing the abdomen, and Stern had covered the raw surface with collodion.

Dr. Robert T. Morris was cited as using aristol to prevent adhesions, because the powder was insoluble in serous fluids and quickly formed a protective covering with the coagulated lymph which could not be brushed off. He based his belief upon experimental work on rabbits. Baum had made experiments in which he covered raw areas with catgut, goldbeater's skin, and prepared animal peritonæum. Kelly advocated the fixing of the uterus by suture in a position of retroflexion, in order to close the cavity of the cul-de-sac of Douglas, and thus prevent prolapses and adhesions of the intestine. Werth advised filling the bladder with boric-acid solution after operating, to prevent the intestines from falling into the cul-de-sac when raw surfaces had been left in that region.

One of the most valued procedures in prevention was the abandonment of the mass ligature for the individual ligation of the vessels in a pedicle, and the covering of its raw surface by suturing the peritonæum over it, as advocated by Stimson in a paper read before the American Surgical Association in 1889. Senn suggested the covering of raw surfaces, wherever possible, with omentum.

As sepsis was a well-known cause, it was scarcely necessary to say that the most absolute adherence to the rules and technique of surgical cleanliness must be followed.

The less we impaired the vitality of the tissues by prolonged exposure, etc., the less infection there would be; therefore, we must avoid traumatism, and keep up the use of moist heat, so that the home-guard army of leucocytes might be kept alive and vigorous, in order that they might be able to repel the bacterial army of invasion which was threatening the organism. The time element in an operation was of the greatest importance, the surgeon's skill being aided by trained assistants and the best environment. Unnecessary traumatism might be avoided in many cases by the Trendelenburg posture, and the intestines should be freely emptied before the operation. The peritoneal surface should be kept covered with gauze sponges wet in hot normal saline solution and the air of the operating-room kept at the highest point of saturation.

The incision should be as small as possible and all blood clots should be removed before closure of the abdomen. The intestines and omentum should be replaced in their normal position as far as possible. The best means of doing this was to fill the abdominal cavity with hot saline solution, which allowed the intestines to float and assume their proper relations and position.

In the after-treatment the most notable measure was the early employment of cathartics to provoke active peristalsis and thus prevent adhesions. This was often hard to do, and the writer made early use of the copious high enema in conjunction with the cathartic. The use of oxygen to inflate the intestines, as recently advocated by Cleveland, must be of great value and should be resorted to as an early rather than as a late measure in the exaggerated Trendelenburg posture. The patient should be encouraged to change her position frequently during the early hours after the operation, in order to break up newly formed adhesions and so that the intestines might be more likely to assume their proper relations. Free motion should not be prevented by a tight abdominal dressing.

Dr. EMMET said that where there was much exposure of the peritoneal surface or abrasion of the peritonæum he used the saline solution as recommended in the paper. He believed in the use of aristol and had had good results with it. He took exception to moving the patient early after the operation, for the reason that he did not believe gases could be dislodged until the bowel had regained its peristaltic tone, and that then it was time to use cathartics and enemata. He thought that early moving of the patient from side to side made her restless and uncomfortable.

Dr. MALCOLM MCLEAN said he had long dwelt upon the importance of moisture in the operating-room and the necessity of a high temperature there. He never operated in a room where the temperature was below 85° F., and usually it had a temperature in the neighborhood of 90° F., with plenty of moisture. He used the cautery merely to whiten or coagulate the tissue, not to char it.

Dr. J. RIDDLE GOFFE believed in changing the patient's position as often as she felt uncomfortable. He thought that gauze in the pelvis prevented adhesion by causing a tremendous outpour of serum, separating and lubricating the surfaces, thus accomplishing the same object as was obtained by filling the abdomen with salt solution. In regard to moving the bowels, he believed that this should be done early, although he was not so insistent about this as formerly. If there were indications

that the patient should not be disturbed, he waited three, four, or five days before pushing active measures.

Dr. WALDO believed that in some cases cathartics added to the depression which already existed, and that the bad effects were out of proportion to the benefits received from early peristaltic action.

Dr. JANVRIN said that, in his opinion, raw surfaces should be covered with peritonæum as far as possible, but where this was impossible they should be touched with pure carbolic acid. He believed in small incisions and in handling the intestines as little as possible. He had used hot saline solution in the abdominal cavity for twenty-five years. The late Dr. Peaslee had used what he called "artificial serum," consisting of a drachm of common table salt to a pint of hot water, for washing out the abdominal cavity, fifty years ago, and to him must be given the credit of first using what was now called "normal saline solution." The speaker had simply extended its field of usefulness for the purpose of preventing adhesions. For such a purpose he left in the cavity about two quarts of the solution, as the best preventive of adhesions. He did not rely upon early movement of the bowels by catharsis, as he had done formerly. He rarely found difficulty in getting good results with high enemata. Failing in this, he gave small doses of morphine, which quieted the nervous irritation and pain.

Dr. BRETTAUER said he agreed with the previous speaker that early catharsis was not only not necessary, but often harmful, as it was impossible to prevent adhesions by causing peristalsis. He found that better results followed operating in the summer time, with the temperature often 100° F. or higher.

Dr. WARD said that the use of gauze in the pelvis to prevent adhesion was a surprise to him, as he was of the opinion that gauze was an ætiological factor in its production. He had also seen morphine used to excellent advantage where catharsis had failed. He preferred giving a high and copious enema early in cases in which the patients had been subjected to severe operations, rather than push the cathartics.

Letters to the Editor.

SEPTIC INFECTION OF UTERINE ORIGIN.

751 MADISON AVENUE, NEW YORK,
March 18, 1901.

To the Editor of the New York Medical Journal:

SIR: Dr. Boldt, in reply to my letter in your issue of March 16th, states that he regrets I should make his paper a basis for personal controversy. There was nothing more remote from my intention than to bring a personal element into the discussion. Dr. Boldt well knows that when I have a personal grievance I address the person directly and do not resort to the columns of a medical journal to state it. The matter on which I addressed you, it seemed to me, had a scientific bearing, and in expressing myself I took particular pains to avoid anything which might be construed as being of a personal nature. In my present communication I shall take the same pains to base my remarks solely upon matters which, to my mind, have a scientific interest, ignoring the personal tone that permeated Dr. Boldt's reply.

The doctor states that I had no facts upon which to base my statement, that in the sentence to which I took exception he had reference to "my papers on puerperal sepsis which have appeared in various journals during

the past three years." I admit that the only facts I had were those furnished me by my sense of hearing in the closing remarks of the doctor in the discussion which followed the reading of his paper at the Obstetrical Society. If my papers were not meant, it might be of general interest to know to what papers he alluded, so that the general profession may be warned against their baneful influence and teaching. Or did the doctor resort to the strategy of setting up a man of straw so as to have something to use as a target and to knock down?

I frankly confess being guilty of the charge the doctor makes that the gray matter of my brain is unable to comprehend the meaning of the term septicæmia (for which I have substituted the term acute bacteriæmia) in his sense, as it is also unable or unfit to comprehend the logic that prevails in his paper on Septicæmia; Acute Bacteriæmia, etc. That the gray matter of other people's brains has shown the same incapacity was evidenced by a specimen which Dr. Boldt himself exhibited at the very next meeting of the Obstetrical Society following that at which his paper had been read. The specimen was an apparently normal uterus (no microscopical examination had been made), removed from a patient suffering from puerperal sepsis. The indications for the hysterectomy were at total variance with those the doctor himself had laid down in his paper at the meeting before, showing that he did not fully comprehend his own teaching. The patient, moreover, died in spite of the doctor; but he thinks my patient "may have got well, not because of her physician, but in spite of him." I have no fault to find with my patients when they get well in spite of me. On the contrary, I am very much grieved and disheartened when they die in spite of me. But, to be serious, Dr. Boldt's specimen showed how easy it is to criticise another man's case, and how difficult it is to determine your indications from a bacteriological examination of the blood.

Dr. Boldt finds fault with me for not showing the same scientific attention to my patient, ill with puerperal sepsis, in which I removed a gangrenous tube and ovary, as did Albert de Pourtales in his case, to which I made reference in my paper. I take some pride in the fact that I did not show my patient the same scientific attention (a lengthy post-mortem report), for my patient recovered and I have since delivered her of a healthy female child at full term.

The doctor continues to dwell on the fact that one of my specimens, the septic uterus with retained placental residue, was criticised because it was held by some who saw the specimen that I should have been able to remove the residue with the fingers or curette. Well, as a matter of fact, I had curetted the uterus; but, as was evident after the operation, I did not remove all the placental tissue—an event which has happened to others as well as myself. I did not see the patient until three days later, when all the symptoms pointed to an early fatal termination. I felt confident that the source of infection was the uterus, which I removed, and the patient recovered. On cutting open the uterus, the placental tissue was found at the fundus and at the left horn, and the whole endometrium was in a condition of septic inflammation. The case resembled in every respect that reported by Sipfel (*Centralblatt für Gynäkologie*, Vol. xviii, p. 667), which Dr. Boldt quotes in approval. It is evident that distance, in the minds of some, throws a certain halo, also, around things medical.

The most carping critic could not take any exception to my second specimen, which was a puerperal uterus

studded with small abscesses varying in size from that of a pea to that of an almond. It was removed from a patient whose temperature was 106° F. and whose pulse was 160. She recovered.

The third specimen was a lacerated uterus removed from a woman over forty years of age, who was suffering from diffuse puerperal septic peritonitis. The uterine walls showed some streptococci, though the organ as a whole showed no marked changes. I stated that I removed the uterus because it seemed to me the best way to carry out thorough drainage, because of the woman's age, and because of the fact that she had a contracted pelvis, necessitating a high forceps operation, with the result of a dead child and a badly lacerated uterus. She also recovered.

My fourth case, also ending in recovery, was the one already referred to, in which I removed a gangrenous tube and ovary, resulting from a sepsis which had originated in the uterus and later extended to the right tube and ovary. Albert de Pourtales's case ran a somewhat similar course, but because it was in Bumm's clinic—the home of bacteriological investigation of puerperal infection—interference was delayed until, after repeated curettings, streptococci were found in the lochia. The patient by this time had become moribund, but was nevertheless subjected to an abdominal hysterectomy, with a fatal termination a short time afterward. Hence the scientific post-mortem attention which the patient received and which has called forth such admiration from Dr. Boldt.

Dr. Boldt endeavors to explain his "change of front" in reference to septic peritonitis by seeking cover under the mantle of terms. He tells us now that when he said "diffuse septic peritonitis" he had reference to the chronic form. This is an adjective which he forgot to use in his original paper, written with such evident care and deliberation. Let us read his description of the form of peritonitis in which, according to him, an operation was contra-indicated: "I have operated upon a goodly number of women ill with acute puerperal septic peritonitis, hoping to save one or another, but so far in vain. The condition found is a large, flabby uterus, the Fallopian tubes congested, but not containing pus, the ovaries macroscopically normal, the intestines distended and the peritoneal surface more or less congested, no adhesions at any place—in short, a septic peritonitis" (*Medical Record*, April 16, 1898, p. 571). In his recent letter the doctor would make a distinction between "acute septic peritonitis dependent upon the rupture of an ulcer or an appendicular abscess, etc.," and that caused by puerperal sepsis. Wherein lies the difference, he does not tell us. Do similar micro-organisms act differently upon the peritonæum when they enter that cavity through other portals than the uterus? This is a strange opinion, coming from one who speaks as an authority upon bacteriological questions.

As I stated on a former occasion, I am fully in accord with the teaching that each case should be investigated from a bacteriological standpoint when feasible. But this investigation, to be of any service, nay, in order not to be misleading, should be carried out only by an expert bacteriologist, and even then not too much weight should be attached, with our present knowledge in that direction, to the bacteriological findings. So far, my experience with such investigations has not been satisfactory. I have called in the aid of experienced pathologists, and before they could furnish me with definite data, the patients have passed into a moribund state in which it

would have been folly to perform an operation. What the future will determine in this direction is as yet an unknown quantity which Dr. Boldt, enthusiastic bacteriologist as he is, must admit. For the present, the safer teaching is that every case of local sepsis, no matter how mild at the outset, should be carefully watched, for we can never be certain that it will not develop into a serious sepsis (or call it what you will) which may be a menace to life.

HIRAM N. VINEBERG, M. D.

Book Notices.

A Text-book of Gynæcology. Edited by CHARLES A. L. REED, A. M., M. D., President of the American Medical Association (1900-1901); Gynæcologist and Clinical Lecturer on Surgical Diseases of Women at the Cincinnati Hospital; Fellow of the American Association of Obstetricians and Gynæcologists; Fellow of the British Gynæcological Society; Corresponding Member of the National Academy of Medicine of Peru, etc. Illustrated by R. J. HOPKINS. New York: D. Appleton & Company, 1901. Pp. xxvi-900.

THIS is a variorum book, but the diversity of authorship has been so cleverly managed by Dr. Reed that there is no overlapping of articles, for he has turned his contributors' words into the third person, at the same time managing not to mask the identity of any one of his collaborators. This seems to us to be a unique and most commendable feature. Another novelty lies in the use of quotations from the text as legends for the illustrations, after the manner of books of fiction. Nearly every one of these legends contains the name of the contributor concerned, so that the reader need never be at a loss to know to whom to attribute the idea illustrated. Nobody but a master of medical writing and a master of men could do these things without muddling the text and giving offense to his collaborators, but Dr. Reed has most skilfully avoided both these errors. The fact that he has succeeded in doing so marks him as a leader, and for that reason, in addition to its other points of excellence, the book will surely take a prominent position among our text-books of gynæcology.

The list of collaborators is as follows: Dr. J. W. Ballantyne, Edinburgh; Dr. J. H. Carstens, Detroit; Dr. Murdoch Cameron, Glasgow; Dr. Henry C. Coe, New York; Dr. John G. Clark, Philadelphia; Dr. F. X. Dercum, Philadelphia; Dr. Walter B. Dorsett, St. Louis; Dr. L. H. Dunning, Indianapolis; Dr. Frank P. Foster, New York (erroneously credited with the title LL. D.); Dr. Samuel G. Gant, New York; Dr. Hobart Amory Hare, Philadelphia; Dr. Malcolm L. Harris, Chicago; Dr. Maximilian Herzog, Chicago; Mr. R. J. Hopkins, New York; Dr. Joseph Taber Johnson, Washington; Dr. Wyatt G. Johnston, Montreal; Dr. Matthew D. Mann, Buffalo; Dr. Thomas Charles Martin, Cleveland; Dr. Lewis S. McMurtry, Louisville; Dr. Dan Millikin, Hamilton, Ohio; Dr. Henry P. Newman, Chicago; Dr. William Warren Potter, Buffalo; Dr. A. Ravogli, Cincinnati; Dr. Charles A. L. Reed, Cincinnati; Dr. Hunter Robb, Cleveland; Dr. James F. W. Ross, Toronto; Dr. A. W. Mayo Robson, Leeds; Dr. J. L. Rothrock, St. Paul; Dr. W. Japp Sinclair, Manchester, England; Dr. Horace J. Whitacre, Cincinnati; and Dr. E. Gustave Zinke, Cincinnati.

Although the work deals largely with operative procedures, as is necessarily the case with any comprehensive book on gynæcology, more space proportionately is

devoted to affections that do not call for operations than is common with text-books. For this Dr. Reed is highly to be commended. It shows, like the general tenor of the book, that the editor recognizes the primacy of general practice. At the same time he puts the necessity of specialism in a remarkably clear way. "Specialism in medicine," he says, "has an ethical basis which cannot be ignored. . . . There is no practitioner but knows and does some things better than he knows and does others, and he is to that extent a specialist. If, however, he were to concentrate his attention exclusively upon those things which he knows best and to ignore those things of which he knows least, his intelligence would move only upon convergent lines. This is indeed the inherent mischievous tendency of specialism, and one which the gynæcologist, as other specialists, should never cease to resist. The sphere of the gynæcologist's labors has already resulted in a broadening of his activities. His constant experience with intraperitoneal conditions has resulted in his expansion into an abdominal surgeon, a fact recognized, not alone by the general consensus of the profession, but, specifically, by the creation in medical schools of professorships of 'gynæcology and abdominal surgery' or of 'abdominal and pelvic surgery.'"

Dr. Reed and his collaborators have covered the ground of the diseases peculiar to women quite comprehensively. We note only two omissions, that of vaginismus and that of coccygodynia; but, as we have not read every page, perhaps it is only from the index that they are missing. The book is one of uncommon originality and one destined, we predict, to become a favorite with the profession. From the mechanical point of view, the volume shows the usual excellence of the Appletons' work, and special mention must be made of the satisfactory quality of Mr. Hopkins's drawings.

A Manual of Surgical Treatment. By W. WATSON CHEYNE, M. B., F. R. C. S., F. R. S., Professor of Surgery in King's College, London, etc., and F. F. BURGHARD, M. D., and M. S. (Lond.), F. R. C. S., Surgeon to King's College Hospital, etc. In Seven Volumes. Volume IV. The Treatment of the Surgical Affections of the Joints (Including Excisions) and the Spine. Philadelphia and New York: Lea Brothers & Company, 1900. Pp. xx-370.

THE authors, in answer to criticisms of former volumes, reiterate the statement made in their first preface, that only such methods as have been found best in their hands have been mentioned. The same general plan adopted in the earlier volumes is consistently carried out in the one before us; we further find practically the same arrangement. The first division includes the surgical affections of the joints, and it is subdivided into sections on the injuries of joints and on diseases of joints in general. Under the head of injuries to joints we naturally find the various forms of dislocations described, and the description of their appropriate treatment follows. The introductory chapter opens with remarks and advice of a general nature, applicable to all forms of dislocations; later, each individual dislocation is fully outlined in a succinct and graphic manner. Our attention is particularly arrested by the eleventh chapter, in which we find a description of the dislocations occurring at the shoulder joint. Here the authors ably consider the advisability of operative intervention in cases in which reduction has not been accomplished, drawing sound and just conclusions.

The surgical affections of the spine are fully consid-

ered; yet there are many interesting facts pertaining to fractures of the vertebræ which we do not find mentioned. A separate chapter has been given to the thermal treatment of rheumatoid arthritis, furnished by Dr. Leslie Walsh, which materially adds to the attractiveness of the book. In conclusion we note an appendix on scoliosis, taken by permission, verbatim, from the book of Dr. Percy Lewis on *The Relief and Cure of Spinal Curvature*. We have spoken most highly of the former volumes of this work, and find no reasons for treating the present one less cordially.

Der Stand der Volksheilstätten-Bewegung im In- und Auslande. V. Bericht. Herausgegeben von Dr. med. G. LIEBE in Braunfels. München: Seitz & Schauer, 1900. Pp. 85.

THIS volume constitutes the fifth report of the efforts made for the sanatorium treatment of tuberculosis in Germany and other countries. It is very complete and of interest to those who are occupying themselves with this phase of medical endeavor.

Klinische und pathologisch-anatomische Studien zur Aetiologie des Uterusmyoms. Von ELIS ESSEN MÖLLER. Akademische Abhandlung. Berlin: S. Karger, 1900. Pp. 106.

THE author has made an exhaustive clinical study of a large number of cases of uterine myomata. He regards their origin as partly embryonal, but not entirely. Some predisposing "irritation" must start the growth of the tumors. This he finds in a great variety of elements, no single one contributing to the sudden development of the neoplasm. Along these lines, he thinks, the question will ultimately be decided. Close anatomical study of the material has gone hand in hand with the clinical work, and the author touches upon most of the interesting phases of the subject of uterine fibroids. The monograph will repay reading.

Experimentelle Untersuchungen über die Einwirkung des Eserins auf den Flüssigkeitswechsel und die Circulation im Auge. Von V. GRÖNHOLM, früherem Assistenten an der Universitäts-Augenklinik in Helsingfors, Finnland. Hierzu 2 Tafeln mit Curven I-XI. Leipzig: Wilhelm Engelmann, 1900. Pp. 620 to 711.

IN this monograph, which embraces mainly experimental work, the author concludes that the main influence of eserine upon the normal eye is the diminution of the intra-ocular pressure, preceded by a temporary increase due to the hyperæmia evoked by the drug. The decreased pressure results from the contraction of the intra-ocular vessels. The author goes minutely into the details of his experiments, showing the grounds on which he bases his conclusions.

Miscellany.

Pernicious Anæmia; Its Antiseptic and Serum Treatment.—At a recent meeting of the Royal Medical and Chirurgical Society of London, Dr. William Hunter (*Lancet*, March 30th) related the case of a man (who was exhibited before the society) aged thirty-seven years, whose symptoms—breathlessness, palpitation, and progressively increasing weakness—had come on very gradu-

ally two years before. The case had previously to coming under observation been regarded as a case of gastric catarrh on account of the discomfort in the stomach. The most prominent symptoms were a constant pain in the stomach and mouth, which was liable to exacerbations, coming on about every three weeks and lasting two or three days, after which the mouth and tongue became each time very sore and the tongue sore. The gastric symptoms consisted of pain in the stomach, nausea, and retching, which were worse when the organ was empty. A curious tingling and numbness of the fingers was complained of occasionally. The history was a very typical one as regards the oral sepsis, extending over eight or ten years, followed eventually by gastric pains. The gradual onset of the anæmia with weakness and with recurrent attacks of gastric disorder and glossitis were also very characteristic. On admission there were four groups of symptoms: (1) Weakness and extreme anæmia and their usual effects, the red corpuscles were only 27 per cent. of the normal and hæmoglobin only 35 per cent., there was also poikilocytosis; (2) hæmolytic symptoms—viz., urobilinuria and a lemon color of the skin; (3) oral and gastro-intestinal symptoms—viz., sore tongue, dental necrosis, suppuration of the gums at one part (which had existed for ten years), and gastric pains; and (4) toxic symptoms—viz., tingling and numbness of the fingers and irregular pyrexia. The treatment consisted of oral and gastric antiseptics, the teeth were scraped, some were extracted, and a mouth wash was used. Mercuric chloride was administered constantly. On July 9th, 13th, and 23d three injections of antistreptococcic serum were administered. After the first the red corpuscles rose to 36 per cent., after the second to 52 per cent., and in the course of three weeks the red corpuscles rose to 65 per cent., the hæmoglobin to 72 per cent., the hæmolysis (as evidenced by the color of the urine) was arrested, and the patient's health slightly improved. The injections were followed by febrile reaction, that after the first was very marked. The temperature during the first week after admission had been variable, between 99° and 97.5° F., but after the injections it became steadier and about normal. The patient was so much better that he went for a time into the country. On September 26th, liquor arsenicalis was added to the other treatment. The improvement continued, the patient gained over 14 lbs. in weight, and on December 20th the red corpuscles had risen to 94 per cent. and the hæmoglobin to 100 per cent. The only symptom remaining was occasional numbness in the fingers. The case, Dr. Hunter remarked, must be regarded as a typical one of pernicious anæmia in its mode of onset and clinical history and the four groups of symptoms present. The case was the first he had been able to treat on the lines he had recently recommended—viz., complete and long-continued oral and gastric antiseptics. These aimed at the removal of the infective cause of the disease and of the septic conditions of the mouth and stomach which favored its operation. Nevertheless, the infection still remained on the tongue and showed periodic tendency to break out afresh. On several occasions the soreness of the tongue had returned, accompanied each time by feelings of illness and increased signs of hæmolysis in the urine, but each time they were checked by strong antiseptic measures. The results clearly showed the beneficial effects of serum treatment, at the same time confirming the infective nature of the disease. The first two doses were 10 cubic centimetres, afterward 5 cubic centimetres were given. In view of the reaction it would be advisable in future to begin with only 5 cubic-centimetre doses and to see that

the temperature was not variable and erratic at the time of the injection. In reply to criticisms, Dr. Hunter said that he had since seen ten cases exactly like the typical case of pernicious anæmia that he had described. The diagnosis was not to be based upon the blood changes alone, but upon the association of these with four definite groups of symptoms—viz., anæmia, hæmolytic changes in the urine, oral and gastro-intestinal symptoms, and fever with other toxæmic symptoms. As to the separation and identification of the organism, the streptococcus was only an associated bacterium and it was not hæmolytic. He had not yet isolated the true specific organism.

Chronic Renal Disease and Insanity.—Dr. W. Baxter Gow, medical superintendent of the asylum at Wellington, N. Z. (*New Zealand Medical Journal*, February), draws the following conclusions from his investigations:

1. That granular kidneys are more frequent in the insane than in the sane.
2. That in the insane they do not give rise to the usual physical signs and symptoms.
3. That the frequency has a distinct connection with the mental condition of the patients. The condition favoring the occurrence of granular kidney is that of motor excitement.
4. That, according to Dr. Craig, a low blood pressure is found in similar cases, whereas in melancholia and delusional insanity the blood pressure is raised. In these latter a normal or merely congested condition of the kidney is found.
5. That in general paralysis the kidneys are sometimes granular, sometimes congested, but they probably vary with the condition of the blood pressure, which has, up to the present, not been satisfactorily investigated.
6. That the cause of the lowered blood pressure, or the lowered blood pressure itself, is probably the real cause of the increased frequency of granular kidney in cases of motor excitement.

Earth Eating.—We have on more than one occasion referred to the practice of earth eating. In our issue for January 5th we published a letter by Dr. Thomas W. Davis referring to the prevalence of the custom in certain districts of the Southern States, and asking for further information thereon. Dr. Rutherford (*Postgraduate*, April; *Indian Lancet*, Vol. xvii, p. 234), referring to the prevalence of earth eating all along the west coast of Africa, says:

"I met with it first at Babni, where there occurs a deposit of yellow clay, containing about fifty per cent. of iron, a considerable quantity of mica, and some quartz particles, but there is evidently a considerable quantity of organic matter in it. The clay is prepared for consumption by making it up into balls about five inches in diameter, and is then baked over a slow fire. When quite dry and ready for use, a small portion is broken off and placed in the hollow of a smooth leaf, and then reduced to a powder between the finger and thumb. The leaf is then gently shaken, to make the harder and more gritty particles fall aside. These are carefully removed, and the residuè is then transferred to the mouth, masticated and swallowed." According to W. Reade, too, says the *Postgraduate*, the Wandingoes of West Africa eat earth, but it is more as a medicine to produce purging. "I saw," he says, "on the thatch of a house pieces of yellow earth which is used for food. . . . I could easily understand it being eatable, as it possesses a most piquant and agreeable odor." On a part of the Gold Coast the blacks eat the red earth from which the giant ant-hills of those parts are made, possibly because it contains a

certain amount of formic acid and so tastes very like acid drops.

Marriage—"with Modern Improvements."—The *Lancet* for April 13th says: A medical correspondent forwards to us a mysterious circular which was recently sent to him, as he thinks it might be of interest to us. The circular is printed in three languages—namely, German, French, and English. The English portion runs as follows:

"Since it may be that this circular could render any great service to any person, I publish it in that way.

"A very rich count and of high position, forty years old, looks by special motifs, a lady of high classe and first rate education as wife, strangers preferred. She must have (principal condition).

"He obliges himself either to pay a great fee or to make a considerable donation for the nomination. My name secures the greatest discretion in this earnest matter."

The "principal condition" is, it will be observed, left out; however, an enclosed slip informs us that further details can be obtained from a ship captain giving an address in Trieste. All sorts of explanations might be given of the omitted passage as to the wife. The German version says simply "she must." Possibly the very rich count is like the prince in so many folk tales—generally compelled to go about in the shape of a boar or serpent or some other unpleasant animal and wishes to be certain that his wife should be a lady of equable mind, or, like the gnome in Mr. W. S. Gilbert's story, his beauty and stature may depend upon his not washing. There is, however, a slip of green paper which perhaps explains matters. On this are printed three lines as follows:

In der Hoffnung (auf Kind)

En ciente dun enfant

Interesting state (w. child).

We presume the very rich count wants an heir, if not from his own loins, then from those of some one else.

The Necessity for Drinking Sufficient Water.—Dr. W. T. Moffet (*Illinois Medical Journal*, February; *Woman's Medical Journal*, March), quoting Fowler, who says that the kidneys act as regulators of the water supply of the blood, taking from it any excess, and when there is an insufficiency, demanding only enough to dissolve the solid constituents of the urine and to facilitate their discharge from the body, asserts that it is too often a fact that this regulating function of the kidneys is rendered void by the continued failure to imbibe sufficient water to satisfy the needs of the tissues and fluids of the body. He thinks that many cases of renal inadequacy and self-intoxication, with all the symptoms which may depend upon these conditions, are largely due to a deficient use of pure cold water. With the free use of water elimination will often take care of itself. Drinking cold water increases arterial tension, reduces bodily temperature, increases peristalsis and biliary secretion, and aids digestion. There is a large class of chronic troubles that are associated with constipation, renal insufficiency, and inactive skin. On inquiry it will be found that a large percentage of these cases drink water sparingly, many none at all. All the tissues suffer, toxins accumulate and the whole organism is poisoned—the patient has self-intoxication. Dr. Moffet has known obstinate cases of constipation and eczema to be cured by the free use of water. Most of these patients appear to entertain a distaste for water.

ATONIA GASTRICA AND A NEW METHOD OF TREATMENT.*

By A. ROSE, M. D.,

NEW YORK.

A NUMBER of pathological conditions of the stomach are caused by insufficient activity of its muscular fibres, diminished activity of its walls, elongation of the suspending ligament of the lesser curvature, the lesser omentum, and gastroptosis.† These disorders may be associated with insufficiency of motor functions and retention of the contents of the stomach beyond the legitimate time; and all these conditions have one thing in common, they are manifestations of relaxation—relaxation of muscular fibres, of the ligament, of the walls, of the stomach.

Some authors name this disorder *myasthenia gastrica*, which, translated, means disease of the gastric muscles; others use the term *mechanical insufficiency of the stomach*, but this latter name indicates only one of the symptoms. There can be no doubt that gastric relaxation, *atonia gastrica*, is the best name.

The words *atonia* and *asthenia* have been employed as meaning weakness, while in reality *atonia* means relaxation, and *asthenia* sickness.

Mechanical gastric insufficiency can by no means be rightly used as a synonym for gastric atony. Gastric insufficiency is the disproportion between the capacity of the muscular forces of the stomach and the demand of labor on these forces. Such insufficiency may occur in a healthy stomach in case the mass of the ingested food is too large, or the nature or condition of the ingesta is unsuitable. By motor insufficiency, we may understand such stagnation as is caused by resistance at the pylorus. Atony may cause insufficiency, but atony is not insufficiency itself; atony may exist without insufficiency in cases in which the resistance at the pylorus is below the normal. On the other hand, atony may be caused by insufficiency, which occurs sooner or later in the case of ectasia of the stomach. Here, relaxation develops as a consequence of over exertion.

A healthy stomach maintains the position of its lower border constant in all positions of the body; not so the atonic stomach. The latter changes its position with the different positions of the body. While the patient is in the upright position, the lower border, that is, the

larger curvature, as well as the pylorus, is sunk down; in the recumbent position, both will rise, and changes from right to left take place according to different positions of the body. Buch (1) explains this change of position as being due to elongation, that is, relaxation, of the suspending ligament of the lesser curvature, and he thinks that while there is no *atonia gastrica* without relaxation of this ligament, neither is there any *atonia gastrica* without *gastroptosis*.

Dr. G. R. Lockwood (2) says: "The descriptions in the books of the symptoms of *gastroptosis* are hopelessly obscure and chaotic . . . characteristic and diagnostic points are few and misleading." Indeed, the symptoms in *gastroptosis* are manifold and numerous, but if we keep in view that there is only one factor, and that this factor is relaxation, we have a characteristic and diagnostic point, and one which, as we shall see, is not misleading, but indicates at once a rational method of treatment, which in most, if not in all, cases, will cause the symptoms to disappear or to become modified. But Dr. Lockwood is right; discussions on *gastroptosis* have been very lively during recent years, and the opinions of the different authors in regard to its *ætiology* differ. They also differ with regard to a number of morbid conditions which have been connected, correctly or incorrectly, with *gastroptosis*. This lively controversy has been the means of enlarging our knowledge in this field. The reader gave a summary of what he thought to be of importance in the literature on this subject, in a paper published about a year ago (3), and he may be permitted to recapitulate from this paper what relates to the relaxation theory.

There can be no doubt that it is of paramount importance to speak first of the *ætiology* of *gastroptosis*, for the knowledge of the *ætiology* in a given case will serve as a guide for therapeutical action. Cases of *gastroptosis* are of importance in everyday practice. The pathological changes in these cases are subject to special therapy, which is as rational as it is in most instances successful. *Gastroptosis* may form part of general *splanchnoptosis*, but it may exist by itself, may happen without coexisting *nephroptosis*; at any rate, it is *gastroptosis* which, in most instances, principally demands our attention, and, most fortunately, the therapy directed against *gastroptosis* is also the therapy of *splanchnoptosis* in general. The displacement of the stomach and other abdominal organs is often an acquired condition, but recent investigations have furnished evidence that a congenital disposition commonly plays a most essential part.

According to different *ætiological* conditions, we have to distinguish different forms of *gastroptosis*. The overlooking of such a distinction between various kinds of *gastroptosis* of diverse origin has given rise to many differing explanations. The different forms of *gastroptosis* have, according to their *ætiology*, distinct significance.

*Read at the meeting of the Gastro-Enterological Society at Washington, May 1, 1901.

†I write *gastroptosis* instead of, as I formerly did, *gastroptosis*. A Greek friend, who had seen my paper with the title *Gastroptosis*, wrote to me:

Τὰ εἰς—σις—ξις καὶ ψις λήγοντα θηλυκὰ ὡς δευτέρον συνθετικὸν, ὅταν μὲν τὸ 1^ο συνθετικὸν εἴνε πρόθεσις, μένουσιν ἀμετάβλητα, οἷον πρόπτωσις, περίπτωσις, διάγνωσις· εἰ δὲ μή, τρέπονται, ἐν τῇ συνθέσει εἰς—σία, οἷον εὐπραξία, ἀπραξία, παλιγγενεσία, ἱερογνωσία οὕτω καὶ γαστροπτωσία·

That is, a feminine noun which ends in *sis*, *xis* and *psis* as the second component remains unchanged when the first component is a preposition, as, for instance, *proptosis*, *periptosis*, *diagnosis*; but if the first component is not a preposition, then in composition the ending is changed into *sia*, as *eupraxia*, *apraxia*, *pallogenesia*, *hierognosis*, and also *gastroptosis*.

Gastroptosis in adults of both sexes may be the manifestation of constitutional defects and anomalies, and, first of all, of paralytic thorax, chicken-breast, or funnel-shaped breast. We find displacement of the stomach in men or nulliparæ of tender and lean habit with narrow, long, precociously ossified thorax, wide intercostal spaces, and frequently Stiller's stigma of fluctuating tenth rib; in short, it is found in persons with typical phthisical habit. Indeed, gastroptosis is very frequently present in phthisical patients, and it is rare in strong and robust people except when caused by trauma or by peritonitic adhesions. There are, exceptionally, cases of movable spleen and kidney, even gastroptosis of purely local nature, happening in robust individuals; in such cases the subjective painful symptoms may be missing. On the other hand, gastroptosis is frequent in poorly nourished individuals and among the feeble saleswomen who are forced to be standing for eight hours or more during the day.

The reason why patients with long, narrow thorax are specially subject to gastroptosis is this: In such patients the diaphragm occupies a position lower down than normally, on account of the increased vertical diameter of the lungs. In cases of emphysema of the lungs and exudation in the pleural cavity there is still a lower level of the diaphragm. In these conditions the organs situated below the diaphragm cannot find sufficient space in the hypochondrium and are obliged to descend. In the constitutional form it is not often that the spleen and liver are sunk down. The kidney, in men with gastroptosis of the constitutional form, is less often felt than in cases of the constitutional form in women.

Among my cases there were three in which the symptoms of gastroptosis had been relieved completely; there was no more abnormal splashing sound until the patients had intercurrent diseases; one of them suffered from severe attacks of malaria, and the two others had influenza. When I saw them again after these affections, gastroptosis had developed anew, and the splashing could be easily elicited over a large area, exactly as was the case before their first treatment. In all diseases which cause muscular weakness in general, like typhoid fever, atony of the stomach will develop itself.

Acquired, especially rachitic, changes of the skeleton may cause relaxation of the abdominal viscera. Stratz (4) has thus described such conditions: When the sacrum is not sufficiently broad, the spinæ ilii anteriores superiores stand too wide apart and the vaults of the ilium are flattened; in some cases the width of the spinæ may be larger than the width of the cristæ, and all this causes the distance between the points of insertion of the abdominal muscles to be greater, and thus their support to be weakened.

The downward displacement of the stomach is associated with change of its form. It assumes in the higher degrees of such displacement, either the shape of a loop with its convexity down, or a vertical position, similar to

that of the foetal period; or, again, a vertical direction has developed by the sinking down of the pylorus to such an extent that the pylorus stands nearly vertically below the cardiac orifice.

Far-down displacement, marked changes of form, and real disfigurements of the stomach, are found in some cases of kyphosis and scoliokyphosis. Fleiner describes a case in which the splashing sound could be produced immediately over the symphysis, while the apex beat of the heart was felt in the axilla. In this case, however, notwithstanding these anomalies in the situation of the viscera, there existed no marked disturbance of the gastric functions.

Next to the constitutional, there are other causes due to local and, as a rule, mechanical disorders, and these disorders may exist in the stomach itself or outside of it.

Permanent motor insufficiency produces gastroptosis, as also do tumors of the pylorus or of the lesser curvature, which are weighing on the stomach. In the latter instances the expelling power of the organ may remain intact.

Gastroptosis may be caused by hernia—hernia of the mesentery, for instance; above all, hernia in the linea alba may give rise to gastroptosis. In these cases also the expelling power of the stomach may remain intact.

Tumors of the spleen and liver may also cause gastroptosis; another group of cases owes its existence to enlargement of the abdominal space. The largest contingent of these is furnished by the postpuerperal types of gastroptosis, and these have been called Landau cases, because Landau first described them thoroughly. This form of gastroptosis may exist without giving rise to symptoms. If a woman has given birth to many children, there occurs a physiological relaxation of the abdominal walls, which leads to a physiological descent of the viscera of moderate degree without symptoms. The Landau form will be well pronounced in cases of women in whom the spine, in its lumbar region, is abnormally curved forward (rachitic affection), and who, during pregnancy, are obliged—in order to keep the balance—to bend backward while the uterus is forced forward to an abnormal degree.

Men, after having been released from obesity by heroic diet or treatment, may acquire gastroptosis. Gastroptosis, in these instances, puerperal as well as after obesity cure, is the result of adaptation to space.

The activity of the abdominal muscles aids in a manner not sufficiently explained in fixing the abdominal organs in their physiological position. Relaxation of this apparatus forms, therefore, the first ætiological momentum in puerperal and in *post-obesitam* enteroptosis. It is true that relaxation of the abdominal muscles is to a certain degree compensated by increased expansion of the intestine, but a complete compensation is hardly ever established. Women who do not receive proper attention immediately after confinement may acquire or suffer increase of pre-existing gastroptosis.

Glénard's whole theory of splanchnoptosia is based on the relaxation of the suspensory ligaments of the intestines, especially that of the transverse colon, and Stiller, the discoverer of the floating tenth rib, says that splanchnoptosia or enteroptosia is a descent of the atonic dilated stomach, of the colon, especially the transverse portion, the kidney (the right or both kidneys), exceptionally of the liver or the spleen; a descent which has developed mostly in tender age, in consequence of general relaxation, especially of the peritoneal suspensory ligaments in individuals with congenital general dyspeptic neurasthenia, tender muscles, lean habit, and slender bone structure manifested in the higher degrees by a floating tenth rib.

The same author remarks: "Boas takes pains to formulate the diagnosis between splanchnoptosia and nervous dyspepsia, but one can plainly see that he is not successful; the same is the case with his attempt to distinguish gastric motor insufficiency from nervous dyspepsia." Splanchnoptosia and nervous dyspepsia are, according to Stiller, identical, and gastric motor insufficiency is its constant, and often only, symptom. As we have seen, there are cases of splanchnoptosia without dyspeptic symptoms, and these are not so very rare, and thus Stiller's view is applicable only to the great majority of cases, or rather it applies only to cases which have been described as nervous dyspepsia.

The question about the relation of typical enteroptosia to all its nervous and dyspeptic attributes and to the well-known picture of nervous dyspepsia, has been answered by Glénard to the effect that in reality there is no nervous dyspepsia, since the symptoms are produced by anatomical changes of abdominal organs.

For a long time the corset and the strings with which the skirts are fastened around the waist were said to play an important rôle in the genesis of the affection, but now their guilt in causing the evil has been adjudged as being only of moderate measure. In those cases which would be most significant to decide this question as to what part the corset and the skirt strings are playing, *i. e.*, in young girls and nulliparæ, it appears that frequently a tight-fitting corset has never been worn because it could not be tolerated. Certain it is that tight lacing, tight attachment of skirt strings, will aggravate an existing gastroptosis, because the compression of the abdomen from the sides is apt to cause displacement of the right lobe of the liver toward the middle, and thereby to cause pressure on the pyloric portion of the stomach, thus favoring development of gastroptosis.

Our text-books tell us that stasis in the venous circulation of the abdominal cavity, stasis caused by heart diseases, and stasis in the system of the portal circulation, give rise to gastric atony.

As remarked already, it is a well-established fact that there exist cases of gastric atony which, for a long time, give rise to no symptoms. Boas reports the case of a seamstress in whom, accidentally, the clinical symptoms

of such atony associated with retention of the contents of the stomach could be established, although this woman did not complain of any suffering. According to Buch, it is not a rare occurrence to find, on autopsy, dilatation of the stomach, the existence of which during lifetime has not been suspected; and Pentzoldt has described and depicted the case of a man who had died from diabetes and pulmonary tuberculosis, but had never complained of gastric disorder; on autopsy, considerable gastric dilatation and gastroptosis were found; the walls of the stomach were remarkably thin. In these cases there existed a compensation, thanks to which the contents of the stomach—notwithstanding the high degree of atony—entered the intestine in proper time. The compensation consisted in relaxation of the ring of the pylorus; that is, of its circular muscular fibres. This compensation presents an analogy to the compensation in valvular diseases of the heart. Some individuals may live for years with an abnormally dilated and displaced stomach, complaining of no, or only of slight, symptoms, as do individuals with valvular affections of the heart, of high degree, who are often unaware of their disease, so long as the compensatory hypertrophy of the ventricle is adequate to counteract the fault at the valve.

But some day the compensation fails, and then appear suddenly, or in a surprisingly short time, all the symptoms of gastric dilatation. It is possible that some of the cases described as acute dilatation of the stomach may belong to this category of cases of failing compensation.

Some years ago I examined, together with Dr. Einhorn, in his clinic at the male department of the German Dispensary, New York, one hundred patients as they came along, without regard to diagnosis in general, for splashing sound of the stomach, in order to establish the significance of this phenomenon (5).

In thirty cases no splashing sound could be elicited. In six of these, food had been taken only from half an hour to two hours before examination. In two cases no result was obtained on account of invincible tension of the abdominal wall. In one case the symptom was found six hours; in two, seven hours; in one, eight hours, and in one, twelve hours, after eating. In sixteen cases the splashing sound could be elicited as far down as, or below, the umbilicus. Out of these sixteen cases there were only nine in which gastric symptoms had been complained of. In thirty-three cases with splashing sound there were no gastric complaints. The fact that stasis in the venous circulation of the abdominal cavity, stasis caused by heart diseases, for instance, favors gastric atony, we found to be confirmed. Among the one hundred cases there were twenty-four heart and pulmonary affections; in nineteen of these a splashing sound could be produced.

When the new methods of the examination of the stomach were first introduced, it was assumed that a splashing sound elicited below the umbilicus in dyspeptic

persons meant dilatation of the stomach. This view was severely criticised and discarded. The term dilatation of the stomach was reserved for that condition in which the food stagnates in the stomach in such a way that ingesta taken the day previous, or even days before, are found in the water on washing out the stomach in the morning. And, after all, the first view was correct; a splashing sound easily produced over a larger area than normal is the symptom of dilatation of the stomach, though, of course, not necessarily of such a degree of dilatation of the stomach as to cause stagnation of food over night.

The fibres of the muscles of the stomach contract tonically. A relaxation of this tonus causes elongation of the fibres, and dilatation of the relaxed stomach is as natural a consequence as dilatation of the blood vessels upon irritation of their inhibitory nerves or paralysis of their contracting nerves.

Relaxation of the stomach may be caused by disease confined to muscular fibres, through affection of their innervation. B. Stiller found in a large number of nervous dyspeptics with floating kidney and splashing stomach, that the tenth rib was movable; that is, movable to such a degree as normally the eleventh and twelfth ribs are movable, not being fastened by cartilaginous, but only by ligamentous, structure to the costal arch. He observed that when there is such a floating tenth rib, there is likewise a floating kidney and a displaced stomach. Although this floating rib is not found in every case of enteroptosia, it was never missing in well-pronounced cases. He thinks that the degree of mobility of this rib corresponds with the degree of enteroptosia and the degree of neurasthenia, while the degree of mobility of the kidney does not allow such a condition.

He found children who had floating kidney, with and without a floating tenth rib, and also children with it, but without floating kidney and without gastroptosis. He believes, however, that the latter will, later on, become neurasthenics and enteroptotics.

He further observed that floating rib, nephroptosis, and gastroptosis were seldom looked for in patients of advanced years. This fact is explained by the circumstance that the subjective enteroptotic symptoms improve with advancing years, and that people who formerly had consulted the physician on account of neurasthenia would not visit him any more with complaints inviting examination for enteroptosis.

A great deal has been written on the relation between anæmia and chlorosis in young girls and displacement of the stomach. It is certainly rational to assume that chlorosis is not the result of gastroptosis, but the manifestation of a constitutional anomaly which simultaneously favors the disease of the blood and the development of the displacement. There exists chlorosis without gastroptosis, and there is a probability that chlorosis may have been the primary evil causing reduction of tone of

the abdominal muscles, and thereby inducing gastroptosis.

Men afflicted with gastroptosis present symptoms of general nervous irritability less often than women.

The important question of the relation of gastroptosis to nervous symptoms, which latter are of frequent occurrence and of manifold kind, has been touched upon already when Glénard's and Stiller's views were given. It remains now to say a word about the name nervous dyspepsia, which is very convenient to cover a multitude of symptoms, but which is not scientific and is misleading. The symptoms called nervous dyspepsia are brought on by anatomical changes of abdominal organs, the foremost of which is displacement of the stomach. We might call the disorder in question ptoseodyspepsia, because this would exactly signify its pathological nature.

Some authors have spoken of a relation between hyperacidity and splanchnoptosis, but, according to my own observation, there exists no rule; ptoseodyspepsia, if I may use the name which I have suggested, manifests itself similarly to hysteria; the symptoms are inconstant and changeable, some cases present even achylia gastrica, but the probability is that hyperacidity is more frequently found in gastroptosis.

Atonia gastrica and splanchnoptosis are caused, as the foregoing remarks demonstrate, mostly by constitutional weakness and require tonics in general. We have, however, to deal directly with the mechanical derangement, and it is rational to apply mechanical treatment as the first and direct means of relief.

As stated already, the activity of the abdominal muscles aids in fixing the abdominal organs in their physiological position. Relaxation of this apparatus forms, therefore, a momentum in splanchnoptosis, and it is the first momentum we have to consider in therapy.

To strengthen the abdominal muscles, different measures have been suggested. They are, in the first place, a substitute for the loss of tone by means of a bandage; next, hydrotherapy, massage, electricity, and gymnastics. Cold douches to the abdomen and sitz baths of short duration have been tried. Massage executed *secundum artem* in the form of éffleurage, pétrissage and tapotement, in connection with Thure Brandt's *Unternieren-zitterwirkung* and faradaization of the abdominal walls, intragastric faradaization and galvanization, have also had systematic trial; but the results, at least in far developed cases, were unsatisfactory. In some instances, some of these procedures are not harmless, but what we gain on the one hand by invigorating the muscles, we may lose on the other by irritating the psyche of a hysterical person. We have to take into consideration that we are dealing with the nervous condition of a patient. But, moreover, all these remedies are illusory in the case of patients of the working class. I might, however, speak favorably in such cases of massage with a cannon ball of five or six pounds' weight, which is cheap, con-

venient, and perhaps more effective than massage with the hands. I might also recommend swimming for such cases, when in season and opportunity is offered, and also, as productive of some good, I might think of the podylaton, commonly, but unfortunately, called bicycle.

None of all the remedies just mentioned will I criticise or discard. They may all in their turn serve as adjuvants to the remedy which has given me more satisfaction in grave cases than all the others together.

The therapy of gastroptosis consists in the attempt to give tone to the abdominal walls, and, if this cannot be attained, to find a substitute for the loss of tone by means of a bandage. My experience has been scarcely satisfactory with bandages as they are made by the patients or the bandager. Except in Landau cases, it seems difficult to have a well-fitting bandage made. Recollecting how well a broad rubber plaster has served me in cases of umbilical hernia when cut in the shape of the abdominal wall, tapering off behind, and securing to perfection the whole abdomen; recollecting, moreover, how well such strapping has been borne, and knowing of what great service it proves in cases of fractured rib, and in some cases of pleurisy, I have used plaster of the form and in the manner described, in cases of gastroptosis. At first I applied the ordinary rubber plaster only. A piece, of the average size of thirty-six by twelve inches, is cut as follows: The large piece is applied as tightly as possible around the abdomen, drawing it well upward, the two ends meeting or overlapping at the spine. The plaster should not include the crest of the ilium, but should run closely along and above it. The support of the abdominal walls is made perfect by the additional application of the two side pieces of the plaster, extending from the hypogastrium over the inguinal and iliac regions and reaching also to, or near, the spine. In applying the side pieces we may use considerable force.

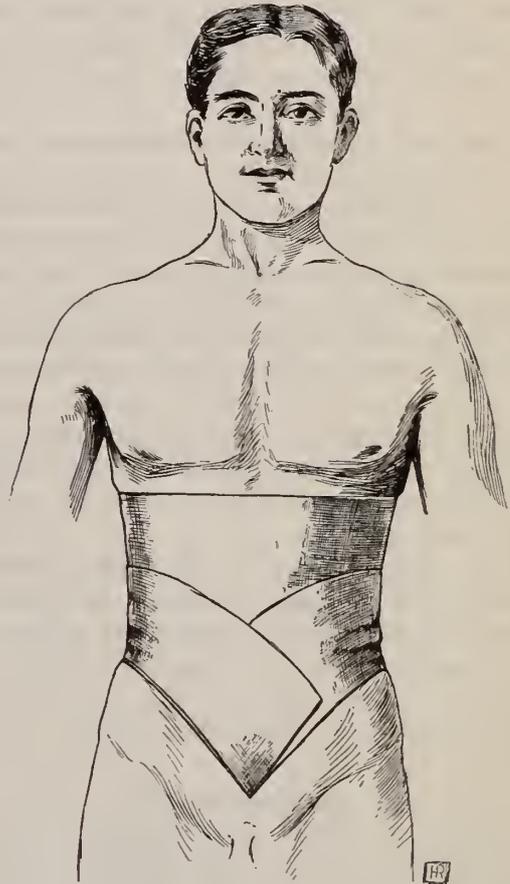

Most patients have borne this plaster without complaining of irritation of the skin, even during the hot weather; a few have suffered from some itching, especially in warm weather, but not enough to require removal of the plaster; while a very few have complained of eczema to such a degree that the plaster has become unbearable and has had to be removed after a week or two weeks, instead of remaining on for five or six weeks, as in the majority of cases.

Availing myself of a suggestion made by Dr. Leonard Weber, I have protected the skin against such irritation by Unna's zinc rubber plaster, and, which I have found better yet, by Dieterich's india-rubber plaster with zinc. These protective plasters have given great satisfaction; hardly any patient will complain of irritation or eczema where this plaster is applied.

I have now a record of about 100 cases in which I have made use of this method of treatment.

Most marked and prompt relief has been afforded in such cases of a high degree of gastroptosis in which reflex cough and reflex vomiting were among the symp-

toms. Patients whose night's rest had been interrupted by almost constant coughing, and whose nutrition had been impaired by frequent vomiting, have enjoyed comfort, after months of distress, at once, the first night after strapping, and have been able to retain at least properly selected food, which they had not been able to do before such strapping. One of the first cases of this kind was that of a woman suffering from pulmonary phthisis associated with gastroptosis. Another case was that of a hard-working woman with gastroptosis, who, notwithstanding her reflex coughing and vomiting, and though forced to attend to housework, was promptly relieved. It is possible that, in this second case, some other treatment in the end might have been successful, but to sub-

ject her to massage, electricity, or hydrotherapy was, on account of the surrounding circumstances, out of the question.

The majority of my patients have been dispensary cases, saleswomen, housemaids, hard-working housewives. In one case of floating kidney, after the plaster had been borne for only six weeks, I observed, for months afterward, that the relief had been permanent, the relaxation of the organs or ligaments suspending the organs, together with the relaxation of the abdominal wall, was no longer found any more; such was, at least, the case when I saw the patient last, six months after the plaster had been removed.

Here is another case:

I. S., twenty-seven years of age, saleslady. Had had

cerebrospinal meningitis, gastroptosis, and nephrop-tosis, anteversion, descensus of ovaries, gastralgia, hyper-acidity, periosteitis of one of the spinous processes of the lumbar vertebræ, and fainting spells. It is true she was subjected at once to treatment of the uterine disorder, the periosteitis, and her enfeebled condition in general, but the principal and decided relief, without which all other treatment might have been of little effect, was given by strapping. Far be it from me to say that the strapping alone is a cure-all in cases of gastroptosis, but it is by all means the most essential in cases of a high degree thereof.

In one case of heart disease complicated with gastroptosis, which I had under observation for two years, I attribute the most excellent results, the marked improvement of the general condition, to the strapping, because, from the time of the first strapping, my patient was able to eat and to digest as he had not been able to do before, in spite of all medical and hygienic measures applied to him.

In one case, a young girl with gastroptosis, was subject to fainting spells several times every day. The plaster was applied in the clinic of the Post-Graduate. No other treatment was resorted to until I had had an opportunity to examine the contents of the stomach. When she came, after having borne the strapping for one week, she reported that her general condition had much improved, and that she had not had her habitual fainting spells. The examination of the contents of the stomach showed achylia gastrica. In this and other cases of women, we have to make allowance for the existence of hysteria, but even so, relief of the gastroptosis cannot be of less importance.

On the whole, in looking up my record, I come to the conclusion that strapping is of great service and gives prompt relief in all cases of gastroptosis of high degree; it is especially valuable where there are complications of lung, heart or uterine diseases.

A case which, in my opinion, is important is the following:

J. M., a boy five years of age, was brought to my office October 10, 1900. Poor appetite, lives on bread and butter and water; absolutely no other food. Has much nausea and vomiting, no pain after eating, and frequently diarrhœa. Enuresis nocturna diurna. Is an exceedingly nervous child, very excitable in playing with brother and sister. Well-pronounced gastroptosis. Ordered strychnine and iron, ablution of the whole body with the damp ice-cold sponge. *October 29th*—No improvement. *November 14th*—Still eats nothing but bread and butter, but a little more than formerly. Bowels now regular. Enuresis nocturna less. *March 19th*—Appetite still poor, but has learned to drink milk. Enuresis nocturna diurna still continues. Apply rubber plaster bandage. *March 27th*—The bandage has remained well in place and has given no discomfort. The general nervous condition has greatly improved; he is no longer irritable, in playing with other children, as he used to be. Now eats everything, even apples and bacon, although the former caused a slight diarrhœa. Enuresis nocturna now seldom; diurna still exists. Case yet under observation.

How well the plaster is borne was shown by the case of a lady in the higher walks of society, to whom I had applied it to relieve gastralgia remaining after a rest cure for gastric ulcer. This patient wore her plaster bandage for over five weeks, during which time she took her accustomed daily bath. When I removed the plaster, after this period of five weeks, the skin was found in perfect condition.

How the strapping is borne under extraordinary circumstances was demonstrated in the case of an acrobat who performed with heavy iron bars in a variety theatre. Notwithstanding his muscular strength, he suffered from gastroptosis and complained especially of reflex vomiting. He was able to perform with the plaster on, and obtained relief from his distressing symptoms. I lost sight of him. He belonged to a company on the road, a one night's stand, but I learned from the druggist who had sold him the plaster that I applied, that he had written from some distant place for another supply.

It is not my intention to give detailed histories in this paper. The principle of the method of strapping for gastroptosis recommends itself without such histories. All I have to say is that my experience has demonstrated that the strapping, in almost all cases, is well borne, is enthusiastically appreciated by the patient, and, although it has to be renewed in some cases, is invariably of permanent benefit. It is to be hoped that this method will at least be given a chance in cases of floating kidney before they are delivered to the operative procedure of the zealous surgeon.

WHAT CONSTITUTES SEXUAL INTEMPERANCE?*

By W. J. S. STEWART, M. D.,

ACTING ASSISTANT SURGEON, UNITED STATES ARMY.

THE statements with regard to the customary brutality of man in general, in his sexual relations with the partner of his earthly joys, as published in your issue for January 5, 1901, in an article entitled Sexual Intemperance, by Jennie G. Drennan, M. D., of St. Thomas, Ontario, Canada, which I have just read, while interesting, are certainly worthy of a passing comment or two.

It is not by any means absolutely clear to the one who reads, just what the writer of the article means by "sex-

*A comment on an article entitled Sexual Intemperance, by Jennie G. Drennan, M. D., in the *New York Medical Journal* for January 5, 1901.

ual intemperance." From the text, however, on page 20, it would seem to be implied that only the period when "the physiology of the female generative organs points" to sexual intercourse is the fitting time for sexual union; in other words, that time best fitted for the propagation of the species, and as the author is arguing from analogy with lower animal life, it is presumable that the term sexual intemperance is meant to designate cohabitation at any other time than during ovulation on the part of the female, and certainly during the periods of pregnancy and lactation.

I have no desire to criticise the statements made with regard to sexual union during pregnancy, more especially during the later period of pregnancy described. I only trust that the average husband has more respect for his partner's pleasure and health than thus to risk destroying either. The advice and information on this subject afforded by reputable physicians to-day living, and those long dead, has always been given when asked for, and has been either followed out or rejected. Even in the latter case, I doubt if the asserted results of sickness, insanity, deformity, and imbecility have been very widespread. There is in the majority of men, even when uncivilized, a certain sense of fair-mindedness and decency which is a factor in such matters.

In regard, however, to the propriety or necessity for abstinence of this character during the period of lactation, it would appear that this subject has assumed undue proportion in the eyes of the writer, carried away, as she is, by her principle that ovulation in the female is the only *raison d'être* for cohabitation. What possible injury to the wife or harm to the husband can arise from the rational use of their mutual privileges during this season? I advisedly employ the word use, as I do not imagine any one is speaking of any great sexual abuse; and certainly there is no reference to any sexual perversion in the writer's paper.

The cessation of ovulation in the average woman during the period of lactation was probably originally designed so that she might have, as it were, a space for recuperation and enjoyment after one gestation, before beginning another, and the nature of the human animal—male and female—being, even in those early days, much as it is now, probably it was deemed safest to insure this period of rest by causing sterility, in most cases, in the female during this time.

Allowing, in accordance with the wishes of Dr. Drennan, that married people should abstain from sexual union throughout the woman's pregnancy and the period of lactation following, in all say twenty consecutive months, at the least, does she not think that such periods of debarment from the sexual privileges conferred by marriage would be more than trying to mutual fidelity and affection and would fill the bars of the divorce court even more full than they are at present?

It is possible, perhaps, that I have misunderstood Dr. Drennan when I imagine that she means that the period

of lactation should be one of abstinence from sexual intercourse. She implies that it should be abstained from until the infant is "capable of subsisting on other than mother's food"! After all, this period does not literally mean that of lactation and may be said to be at an end as soon as begun. Children, fortunately, are always capable of subsistence by other means than that of a woman's breast.

Dr. Drennan overlooks something when she says: "If in the lower animals there is a time for sexual union, why not so with man?" The genus *homo* is not quite physiologically and psychologically the analogue of the lower animals. In the females of the lower animals—let us take the common domesticated animals for example—there is certainly a well-marked period during which the subject submits or responds to sexual union with her mate (and in the majority of cases fecundation is the result), but it only needs a very casual observer to perceive that there is no such fixed period on the part of the males of the same species. They apparently resemble their human relatives in this respect.

This is a case of the female at certain periods submitting to, allowing, and perhaps responding to, the advances of the male, although it is fair to presume that by both parties the act is attended with—as the writer puts it—"a certain amount of satisfaction," even among the beasts.

In regard to this period—that of ovulation—in women being the proper time for sexual union, it is only necessary to recall the contrary opinion of peoples the world over, *e. g.*, the provisions of the old Mosaic law, although physiologically, and also from analogy with lower animals, this is the most favorable period for the propagation of the human species. However, the world has been well peopled so far, and a due regard to the inviolability of women at this period fairly well observed.

But laying aside, in the consideration of the specified period for sexual union of the females of the lower animals, the question of that being the only period when the female will receive the male, the lower animals show another marked difference from the human species, in that this time is also for them the period when the female and the male are most attractive to each other. The courtship of birds and many animals is not at all one-sided, as naturalists know well.

This has, however, no true analogy in the case of men and women, for the woman is at all times, speaking broadly, a subject of sexual attraction for the man, and at all times—save usually at that period of ovulation referred to above, and this by reason of custom and knowledge of the fact that fecundation is more apt to occur then—willing to receive his sexual company; that is to say, that, save in certain not well-defined degrees in sporadic cases, she is equally ready at one time as at another, so far as any physiological process may be concerned, to enter into sexual union with him.

It seems to me, therefore, that it is mainly the *abso-*

lute refusal of the female, together with the lack of attraction on her part for the male, when not ovulating (both reasons may be really essentially the same), which is the barrier to sexual union among the lower animals at other than the fixed periods of the female. Well-regulated morals, superior intelligence, and thoughtfulness for the partner's welfare are certainly not factors in this practically enforced continence.

As stated above, we mortals are, alas! not constructed on these lines. The human female was created with, or has advanced by evolution to, the ability and willingness for sexual union at other than ovulation periods. Why this is so, it would be impossible to conjecture, unless it be that sexual union in the human family might be imagined to have for its purpose more than the one object of the propagation of species.

To the ordinary thinker this would seem to be the case. Dr. Drennan compares the sexual function to that of digestion—functions to be used only for their usefulness in producing certain results; in the one case, offspring; in the other, nourishment.

The taste bulbs and sense of taste are certainly not necessary to the function of digestion, although pleasant adjuncts thereto. Digestion could have been carried on just as well without them, but a great deal of harmless pleasure would thus have been lost to men and women the world over. Gormandizers and epicures from the earliest days may have abused this pleasure, as the drunkard has abused his taste for spirits, but that is no reason why we—the great majority after all—should hesitate before partaking of our "hot bird and small cold bottle" (when we are lucky enough to be able to satisfy our taste), on the plea of palatability not being necessary to digestive procedures.

And in the same way, in the majority of cases, the sexual privileges afforded by marriage, while often not indulged in for the express purpose or with any intention of propagating the species, ought to be quite as harmless morally or physically as the pleasure afforded by the repast referred to. It is a grave mistake to abuse one's digestion, and it is quite as grave a one to abuse one's own reproductive organs or those of others; but it is more than probable that they are hardly abused by either party, or the woman injured, to the extent inferable from the wording of the article under consideration, although as an average thing these same marriage privileges are enjoyed at times other than that designated by the writer, and probably more frequently.

The inference that women are forced—made slaves sexually by their brutal husbands—is, of course, a different matter, and one in which the woman has a just cause for complaint wherever it occurs. There are also men who beat, poison, and otherwise maltreat their wives, but they are *certainly* not in the majority.

Many people, however, are doubtless forced into much that they might have succeeded in avoiding altogether had their wills been a trifle stronger, their influence with

the suggester of the unpalatable act a little greater, or their own secret desires a little weaker. *Non omnes dormiunt, qui oculos clausos habent* has been remarked of alleged cases of rape, where the woman alleged that she had been ravished while sleeping. There are more ways of saying "no" than one. The average man is *not* a brute, and has some degree of thoughtfulness for his wife's pleasure, even when balanced against his own sexual desires.

I will not touch on the desire of women "to rid themselves of this function of the propagation of species" or upon the more serious one of abortion referred to by Dr. Drennan, beyond saying that probably to the thoughts of most people entering the married condition this propagation of species and sexual union—although closely allied subjects physiologically—are entirely different matters.

The former is a possible result of the latter, not its end and object, as seen by them. Nevertheless, it has not been the general experience of practitioners that in anything like the majority of cases there is any lasting grievance on the part of the *married* female when fecundation has followed cohabitation.

As is well known, dissatisfaction with maternity among *married* women is an evil more common in what are known as the upper walks of life than in the great masses of the world's population, and even then it would seem that the word maternity is a wrong one to use in this connection; dissatisfaction with *the state of pregnancy* and its attendant inconveniences, and enforced self-denials, especially among young pregnant women would be a truer arraignment against the woman, as there are happily but few mothers who do not ultimately rejoice that "a son is born into the world."

Dr. Drennan is certainly correct in implying that the prevailing ignorance on these matters of physiological structure of the sexual organs, and on the importance of their proper use and abuse, is greatly to be deplored; but it is a dearth of knowledge that, let us hope, will be gradually diminished by the growth of more general information with regard to the structure and *modus operandi* of our earthly tabernacles.

However, that day is yet far away—and it will be a pity, from a moral, ethical, and psychological standpoint (and probably from a physiological one as well), if it ever arrives—when the newly married couple shall commence housekeeping with a calendar marked as to physiologically appropriate dates for sexual union.

But if ever it should arrive, as a result of the great enlightenment of our race, it is fair to presume that, by that date, adaptation in our nature and structure will also have occurred, by which means the human being will have been changed so as to allow of the inception and continuance of such a delectable state of affairs.

Otherwise the aforesaid marked calendar will, by mutual consent of all parties concerned, be relegated to the waste paper basket without delay.

ARGAO, CEBU, PHILIPPINE ISLANDS.

THE PATHOLOGY, DIAGNOSIS,
SPECIAL PROPHYLAXIS, AND TREATMENT
OF TUBERCULOSIS OF THE SKIN.*

By JOHN A. FORDYCE, M. D.,

NEW YORK,

PROFESSOR OF DERMATOLOGY AND SYPHILOLOGY IN THE UNIVERSITY
AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

It is only in a comparatively recent time that cutaneous tuberculosis has been definitely separated from other skin affections with which it is closely allied clinically. The old designation, lupus, which is still used to specify that form most frequently met with, would, in its strict meaning, be equally applicable to certain syphilides and to rodent ulcer. Before the days of exact bacteriological diagnosis these maladies were frequently confounded by the dermatologist as they are now by many practitioners whose opportunities have not afforded them the needed skill in diagnosis.

The number of affections which are now included under the general term of cutaneous tuberculosis has been considerably augmented since lupus vulgaris was found to contain certain tubercle bacilli and to be capable of conveying tuberculosis by inoculation experiments. It now includes acute tuberculous ulceration usually met with about the mouth or anus in patients suffering with pulmonary or intestinal tuberculosis; lupus vulgaris and its clinical varieties; verruca necrogenica or post-mortem wart, and certain conditions called scrofulodermata when the skin is involved secondarily by extension from ulcerating lymph nodes, tuberculous osteomyelitis, or from subcutaneous deposits called scrofulous gummata. The tuberculous nature of all these affections has been definitely established by the usual bacteriological and experimental methods. They differ, however, in their clinical manifestations and pathological anatomy, so that we are perhaps justified in continuing the use of the clinical terms which have been so long associated with the varied conditions. It is not sufficient, therefore, to make a diagnosis of tuberculosis of the skin, but we must define in more exact terms the special form with which we have to deal.

In the acute form of tuberculous ulceration about the orifices, bacilli of a high degree of virulence are inoculated in fissures or in some minor lesion, and produce spreading ulceration with ragged undermined edges and the presence of miliary tubercles. Such lesions are usually painful, show no tendency to heal, and slowly infect the contiguous parts.

Bacilli can readily be detected in the secretion or scrapings from these ulcers. In this respect, and in the virulence of the infecting organisms, this form differs from all other varieties of the affection in question, and notably from lupus vulgaris where the bacilli are very few in number and difficult to detect in sections of tissue.

Lupus vulgaris is characterized by so many distinc-

tive features that it almost deserves to retain its place as a definite morbid entity. In its remarkably slow and indolent course it presents a striking contrast to the superficial serpiginous syphilide with which it is so often confounded. Its ravages are generally limited to the skin and superficial tissues, and, though producing marked deformity of these organs, unlike syphilis or epithelioma, it rarely involves the bones.

The characteristic lesion of lupus is a peculiar yellowish and brownish-red nodule, somewhat translucent, which is situated deeply in the skin. It spreads by the formation of new nodules, which destroy the invaded parts by ulceration or atrophy. The lupus nodule, when obscured by surrounding hyperæmia, may be rendered visible by pressure with a piece of glass, as a microscopic slide, which empties the hyperæmic vessels and brings into clearer view the new formation. The disease may be limited to a single patch and remain as a small localized lesion for many years. On the other hand, numerous lesions may by their coalescence involve large areas of the skin, presenting central scar formation with peripheral active development. The recurrence of lupous nodules in the scar tissue, spontaneously formed or following operative interference, is of common occurrence, and no case can be regarded as cured when such nodules are revealed by the diascopic method to which reference has been made.

As with tuberculosis of other organs, after a period of active extension the process may remain quiescent for a long time. It may again become actively inflamed, ulcerate, and be followed by enlargement of the communicating lymph nodes. It has been noted that scarification or curettage of a lupous patch is sometimes followed by swelling, redness, and other evidence of an acute inflammation similar to the phenomena which appear in lupous tissue after a tuberculin injection. A generalized tuberculosis has been observed by Besnier to follow scarification of lupous patches, and such treatment has been condemned by him for this reason. Secondary infection with pus-producing organisms may give rise to considerable discharge and crusting of the original affection, so that its features are so obscured as to render a diagnosis at first inspection difficult. I have in mind a case of lupus of the arm of some fifteen years' duration in which various diagnoses had been made on account of this complication. After the use of local antiseptics the original condition was brought prominently to view and the proper treatment successfully carried out.

The lupous process presents certain peculiarities which depend somewhat on the locality involved. An excessive development of fibrous tissue may take place around and in the morbid tissue, which tends to arrest the progress of the new growth and to produce the variety to which the name sclerotic lupus has been applied. Frequently recurring inflammation and lymphatic infection of lupus of the extremities result at times in the production of a pseudo-*elephantiasis* in which the original

*Read before the New York State Medical Association, October 1900.

disease may almost disappear, or only be recognized here and there by a careful examination. In lupus verrucosus the epithelial layers of the skin undergo hypertrophy, and this is specially noticeable in the hands and feet, where the epidermis is normally thick.

The bacilli or their toxins undoubtedly have a stimulating effect on epithelial proliferation, as seen in the post-mortem wart and in tuberculosis verrucosa of Riehl and Paltauf. The new development of epithelium tends to circumscribe the lupus nodule and disguise to some extent its true character. In such case the bacilli do not penetrate deeply and the reaction in the derma is rather superficially situated. The prognosis is correspondingly better, as there is less tendency to recurrence after the removal of the affected skin.

This epithelial hypertrophy has a direct bearing on another complication of lupus, viz., epithelioma, which occurs with sufficient frequency as to indicate something more than an incidental relationship.

The morbid condition of the connective tissue permits a more rapid development of the growing epithelium, so that we have a tumor of more malignant type than when independent of such a connection.

The prognosis of epitheliomas which develop in lupus is of greater gravity than that of the ordinary surface epithelioma.

Secondary Tuberculosis of the Skin—The So-called Scrofulodermata.—From a clinical standpoint the so-called scrofulodermata are to be sharply distinguished from the primary forms of skin tuberculosis, which have been defined. They generally follow tuberculosis of the lymph nodes, the lymphatic vessels, tuberculous osteomyelitis, or tuberculosis of the tendon sheaths, bursæ, etc. Adhesions form between the underlying morbid process and the skin, and fistulous openings appear, giving rise to the familiar clinical picture.

A lupus vulgaris of the skin, with its brownish-red nodules, has exceptionally been observed to start from such discharging fistulæ. On the other hand, the cutaneous and subcutaneous lymphatics have become infected by a skin tuberculosis, resulting in secondary abscesses along their course. These are exceptional occurrences, however, as the two types of tuberculosis generally preserve their distinctive features. As in lupus vulgaris, which is imitated so closely by the serpiginous syphilide, so the scrofulodermata find in the syphilitic gummata striking resemblances, and demand more than a passing observation to reveal their true nature.

In addition to the forms of tuberculosis which have been touched upon, and which are of known bacillary origin, there is a growing tendency, especially in the French school of dermatology, to group together a class of dermatoses which occur with more or less frequency in subjects of tuberculosis. These affections, which include lupus erythematosus, lichen scrofulosorum, and various disseminated papular and necrotic eruptions, are

considered to be due to the soluble toxins of the bacilli carried to the skin from some extracutaneous focus.

The general term tuberculides, or toxituberculides, has been proposed for this group of cases; the arguments used to support their toxic origin are the following: In two thirds of the cases there is present a tuberculosis of the lymph nodes or viscera; the lesions themselves, with the exception of lichen scrofulosorum, are free from micro-organisms; inoculation experiments give negative results; and the eruptions are symmetrical in distribution and some of them closely resemble true tuberculous lesions.

In certain rare forms of lupus erythematosus the outbreak on the skin is accompanied by fever, albuminuria, acute pulmonary tuberculosis, bronchopneumonia, and rapid death.

Histological examination of the excised pieces of tissue usually shows, not the ordinary structure of tuberculous tissue, but marked vascular changes, consecutive necrosis, or slow degenerative changes in the connective tissue, leading to its atrophy.

Cultures of tubercle bacilli have been shown to contain a necrotizing substance and the evolution of these various lesions may depend in some way on the action of such a chemical poison on the blood vessels of the skin.

The theory proposed is an ingenious one and affords an explanation of those rapidly fatal cases which have been described by Kaposi and others.

In the majority of cases lupus vulgaris is probably due to accidental inoculation of the tubercle bacilli on the skin or adjacent mucous membrane. The infection may take place on some abrasion, fissure, or some other skin lesion. Direct inoculation has been observed to follow vaccination, tattooing, and accidental pricks with needles or other objects, which had come in contact with tuberculous matter. Latent tuberculous lesions of the nasal cavity may infect the lymphatic vessels and cause the disease to develop in a symmetrical manner over the face.

The possibility of infection through the blood stream is not excluded, for a generalized eruption of skin tuberculosis has followed measles and other infectious processes.

Age is a strong predisposing factor in lupus, for more than seventy-five per cent. of the cases begin before the age of twenty. The more delicate structure of the tissues in the young favors the penetration and growth of the bacilli.

As to the probability of generalized infection following the local disease, the greatest difference of opinion exists. Leloir has reported ten cases of general tuberculosis in seventeen cases of lupus. Other statistics agree in the main with this writer. On the other hand, certain dermatologists have never seen lupus followed by general tuberculosis. We know that it frequently exists for thirty years or longer, and yet exerts no deleterious in-

fluence on the general health. It may even confer a certain degree of immunity to the affected individual.

Histology: The structure of the lupus nodule is similar to that of other tuberculous tissue. It consists of a network of connective tissue enclosing numerous collections of cells which have been variously designated epitheloid, plasma cells, and uninucleated leucocytes. Giant cells are frequent in the new growth, which extends deeply in the corium or to the subcutaneous tissue.

In warty tuberculosis epithelial hypertrophy predominates and the tissue reaction is more superficially seated. The cells of the new growth soon undergo degeneration, probably owing to the action of the tubercular toxins; the centre of the invaded tissue clears up, while steady progression takes place at the margins.

Bacilli are few in number and difficult to detect by the ordinary methods. They can sometimes be found in greater numbers by crushing a small piece of freshly removed tissue between two slides and staining as in ordinary sputum examination.

Inoculation experiments are usually successful. It is probable that in lupus we have a form of tuberculosis due to some attenuation or modification of the virus and for this reason its slow clinical course is to be explained.

Diagnosis: A number of chronic affections of the skin manifest themselves by a deposit in the derma, which shows a tendency to clear in the centre while spreading at the edges. Aside from lupus, late syphilis and certain forms of epithelioma progressively infect the skin in this manner and are not infrequently mistaken one for the other. Nodular or gummatous syphilide of the skin is much more rapid in its evolution; it lacks the translucent nodule which is present in lupus. It is firmer in consistence and does not tend to invade the scar tissue. There are usually other concomitant marks of syphilis about the skin or mucous membranes, which assist in diagnosis of doubtful cases. At times we must have recourse to the therapeutic test.

The diagnosis of serpiginous epithelioma is not so difficult, for we are aided by its onset late in life and by the presence of elevated waxy-looking margins due to the proliferating epithelium. A microscopic examination should remove all doubt, which is not always the case when we are looking at lupus or syphilitic tissue. When epithelioma develops on a lupous surface the question of diagnosis is somewhat more complicated. Lupus erythematosus is characterized by symmetrical erythematous patches, sometimes scaly, terminating in central atrophy, but having no lupus nodules. It is also a disease of adult life, but not exclusively so.

Glanders and actinomycosis of the skin are rare conditions which have more of a theoretical than practical interest in connection with the diagnosis of cutaneous tuberculosis. The possibility of their occurrence, as well as of that of sarcoma and leprosy, should, however, be borne in mind in unusual cases.

Blastomycetic dermatitis and skin infections due to

a protozoon are late candidates for diagnosis. They have been confounded with forms of skin tuberculosis and with dermatitis due to staphylococcus infection. In these unusual infections, which were first described by Gilchrist, there are epithelial proliferation, numerous miliary abscesses, and giant cells in the skin; in fact, many of the gross as well as the minute characteristics of tuberculosis. The protozoa or blastomycetes are not, however, difficult to detect with the microscope, while inoculations for tuberculosis fail.

Some unusual types of streptococcus and staphylococcus infection of the skin present somewhat similar appearances at times, and can only be distinguished by bacteriological research.

Late syphilis may infect the lymph nodes as a gummatous infiltration, and is difficult to distinguish from tuberculous infection of the same structures. Deep cutaneous or subcutaneous gummata in both infections may closely simulate each other, but can usually be distinguished by carefully estimating all the accompanying conditions. Tuberculosis is here, as in the superficial tissues, a slower process than syphilis.

Little can be said as to the special prophylaxis of cutaneous tuberculosis aside from the general hygienic laws which pertain to tuberculosis in general. Accurate diagnosis of early manifestations when the skin is primarily involved, ought to insure radical treatment and prevention of its extension. As a matter of fact, the cases are usually well marked when they first come under observation, so that early destruction of the lesions is precluded.

When extension from underlying lymphatic structures or bone takes place, the surgical rules which apply to these lesions should be carried out.

The education of the masses as to the infectiousness of tuberculosis, together with personal cleanliness, should be effective in preventing some cases of local tuberculosis.

Treatment: The treatment of tuberculosis of the skin depends on the form in question, the extent of tissue involved, and the locality implicated. Tuberculous ulceration about the orifices is usually preceded by grave pulmonary or intestinal tuberculosis in an advanced stage. We have to content ourselves in most cases with local remedies which alleviate without holding out any prospect of permanent cure. Iodoform is one of the best of these, as it relieves pain besides promoting healing. Should more radical measures be deemed expedient, the Paquelin cautery under local anæsthesia enables one to penetrate deeply without loss of blood.

Anatomical tubercle and other forms of papillary tuberculosis of the extremities are best removed with the sharp curette after local anæsthesia with the chloride-of-ethyl spray.

The morbid process is superficial, being mainly in the epidermis and papillary region, and generally shows less tendency to recur than ordinary lupus.

Numerous surgical and dermatological methods have

been employed in treating lupus vulgaris, the best of which comprise total excision of the patch with skin grafting; destruction of the diseased tissue with chemical caustics, the Paquelin or galvanocautery, curettage, linear scarification, and finally the concentrated chemical rays of light, as proposed by Finsen, of Copenhagen. Lang, of Vienna, is at present an enthusiastic advocate of the excision of lupus tissue, and reports over sixty per cent. of cures in thirty-five cases operated upon. This method is to be recommended in a certain class of cases. It is not, however, applicable to cases of wide extent, or where the affection is seated about the eyes, nose, mouth, etc. Lupus of the face in general is not well adapted to this form of treatment.

Lupus tissue may be destroyed by chemical caustics, such as nitrate of silver, chloride of zinc, arsenious acid, and agents of like character. They are, however, much less frequently employed than in former years, and chiefly after the morbid tissue has been scraped away with the curette.

As the lupus tissue is much softer than the surrounding skin it can readily be removed by curettes of various shapes and sizes, leaving much of the normal skin intact, and preventing the disfiguring scars which result from more active surgical methods.

When the lupus nodules are too small to permit their removal with the curette, the dental burr, as recommended by Dr. Fox, can be made to penetrate to the bottom of the lesion and complete its destruction. There is much less probability of a recurrence of the lesions if a chemical caustic is applied to the resulting raw surface. Chloride of zinc and pyrogallic acid are the best of these. The former may be applied, either pure to a limited surface, or in the form of a paste if a larger surface is to be treated. Pyrogallic acid is a milder caustic, but has a more or less selective action, like arsenic, on pathological tissue. In special localities, like the eyelids or external ear, the Paquelin or galvanocautery is an excellent supplementary measure. The actual cautery may also be used to destroy relapsing nodules, and is chiefly relied on where the mucous membranes are implicated.

Linear scarification is not a favorite method of treating lupus in this country, although its advocates assert that it produces less disfiguring scars than the methods touched upon in this paper. It is tedious, painful, attended with considerable loss of blood, and open to the theoretical objection that secondary tuberculous infection may follow.

Dr. Finsen's method by concentrated light, which has been filtered of its heat rays, is now attracting some attention. It has doubtless cured some cases, but is exceedingly slow in its action, requiring several months to effect a resolution of the disease. Similar results have followed the use of the Röntgen rays.

Tuberculin, though practically discarded in the treatment of lupus on account of the danger of disseminating the disease, has undoubtedly rendered a number of cases

in which it has been used more amenable to local treatment, and seems to have prevented recurrences. It has lately been revived by Hallopeau, in France, as a local remedy. Applied to lupus tissue, it is followed by a pronounced reaction and subsequently by a diminution in the infiltration. Used in this way it is perhaps worthy of further study.

The treatment of the ordinary forms of scrofuloderma is purely surgical and is too well known to require further elucidation.

66 PARK AVENUE, NEW YORK.

PRIMARY CHANCRE OF THE SÆPTUM OF THE NOSE.*

By W. FREUDENTHAL, M. D.,

NEW YORK.

EXTRAGENITAL infection with the syphilitic virus is nothing new, and its occurrence is rather too frequent to be especially noticed. Still, the cases described below offer some unusual features which are of more than ordinary interest.

The primary lesion in and about the mouth is, perhaps, chiefly met with in these cases. The transmission by kissing and through drinking cups is probably the most common means of conveying the disease to the innocent. That these sources of infection can and ought to be avoided there is no doubt.

Cases of initial sclerosis of the tip of the tongue and of the tonsils are also reported here and there. In this connection I might mention a case which I saw only a few days ago. It concerned a man, thirty-two years of age, who was referred to me by a colleague in St. Louis. This young man is a drummer by trade and a fellow who comes in contact with all sorts of men and women, especially when he is drunk. About two months previously to his first visit to me he noticed a sore on the tip of his tongue that steadily grew larger. It is not painful, but he feels it when he eats sugar. On examination I saw an ulceration on the tip of the tongue of the size of a bean. It looked whitish, as he had been using astringents on it. The submaxillary glands of the right side and the anterior and posterior cervical glands were very much swollen; the corresponding glands on the other side were also enlarged, but to a less degree. There was, moreover, a papular eruption on his body. All these together made the diagnosis of syphilis absolutely sure, and it was also beyond doubt that the initial sclerosis had appeared on the tip of the tongue. Where and how he acquired this chancre of the tongue the man avers that he does not know.

The most interesting contribution on this subject was published some eleven years ago by A. Pospelow (1). His experience covered a period of ten years. The total

*Read before the Metropolitan Medical Society, April 23, 1901.

number of extragenital syphilomata observed by him during that time amounted to 198 cases. Of these there were on the lips 49 cases; on the tongue, 3 cases (one in a man and 2 in women); in the pharynx, 46 cases (14 in men and 32 in women); on the mammæ, 69 cases; on the chin, 1 case, in a woman; on the nose, 1 case, in a man; on the eyelids, 3 cases, in men; on the trunk, 10 cases, in men; on the anus, 5 cases, in women; on the upper extremities, 6 cases (3 in men and 3 in women); on the lower extremities, 4 cases, in women. Out of these 198 cases, 145 were in women and 53 in men. The preponderance of women affected is greatly due to their being infected on the mammary glands by syphilitic nurslings. Just half of these cases (ninety-nine) were in and about the mouth. It is beyond doubt, says C. Bruhns (2), that only in the very rarest instances were these primary lesions acquired through abnormal sexual practices. The usual way of infection was by kissing persons with recent syphilitic lesions, or frequently through the use of infected drinking vessels, forks, and other utensils employed in domestic life, as well as in various vocations. To the latter category belongs the syphilis of the glass blowers, which in former years was not infrequent. The practice of passing the blow-pipe quickly from mouth to mouth caused whole epidemics of luetic infection in single factories. Pospelow mentions especially that primary chancre in the mouth, due to the common use of domestic utensils, is much more frequent in the lower classes of the population, where absolute ignorance of the above-mentioned dangers frequently goes hand in hand with total lack of cleanliness. These cases are no longer curiosities, but are of great importance from a clinical point of view. "La connaissance de ces contagions insolites excentriques, extraordinaires," says Fournier in his *Leçons sur la syphilis* (1881, p. 43), "n'est pas seulement affaire de curiosité; elle comporte un intérêt sérieux, un intérêt véritablement clinique."

Of even greater interest are the primary chancres of the nose. There are but few cases recorded in the literature, and I shall mention these here briefly. Pospelow (*l. c.*) mentions one case of a man, thirty-six years of age. The sclerosed primary ulcer occupied the whole of the right ala nasi. The submaxillary glands were enlarged and hard to the touch, both conditions being more pronounced on the right side. The infection had taken place most probably through a towel used by several of the patient's roommates, one of whom was without doubt syphilitic. According to O. Seifert (3), however, the first one to report such a case was Spencer Watson.

M. Krelling reports from the poliklinik of Lesser, in Leipzig, the case of a woman, thirty-five years old, with primary sclerosis, also of the right ala nasi.

A. Morel Lavallée (4) saw two cases of primary syphilomata "on the nose." N. S. Speransky (quoted by Pospelow) treated a case in which a hard chancre developed after a bite in the nose. William C. Wood (5) describes an interesting case in which, in a drunken row,

a man who had struck a companion on the mouth, just scratching his own skin, or, as he stated it, "hardly drawing blood," had contracted syphilis. Wood was treating the person struck for syphilitic sore mouth, so there was no question about the correctness of the diagnosis.

A paper on this topic would not be complete without mention being made of Dr. L. Duncan Bulkley's valuable book on *Syphilis in the Innocent (Syphilis insonitium)*. Bulkley gives a table comprising 7,123 cases of syphilis reported by different authors. Of these, there were 353 extragenital cases, or almost 5 per cent. of the entire number. But he believes that extragenital chancres are much more frequent and that they probably amount to 10 per cent. of all the cases.

In Table III he reports 9,058 cases of extragenital chancres collected from various countries; of these, 95 were on the nose, but Bulkley does not give more particular data regarding the seat of the lesion. Bulkley himself saw one case of primary chancre of the ala nasi.

I have to mention, further, E. Laurent (6), who observed a case of a man who presented a primary hard chancre at the root of the nose two months before the eruption of the skin appeared. A. Jacobi, of Königsberg, Prussia (7), found a primary nasal lesion on the middle turbinated of a married sergeant, the mode of infection being unknown.

Another case, in a woman thirty years of age, was reported in an interesting paper by Joseph A. Kennefick (8). There was a shelving ecchondrosis of the sæptum, and on top of this a "characteristic punched-out ulceration with well-defined border, rounded and elevated, and a dirty yellowish base." According to G. Le Bart, altogether 35 similar cases have been reported.

Perhaps to this same class belongs a case described not long ago by George L. Richards, of Fall River, Mass. (9). He says: "Students of Hajek's Clinic, in Vienna, will recall a case of primary chancre of the nose he was wont to describe. The victim was a physician who had examined a woman *per vaginam*, not knowing at the time that she was syphilitic; subsequently he picked his nose with the finger, and inoculated himself with syphilis, the insufficiently cleansed nail carrying the virus." Dr. Richards does not state on what part of the nose the chancre first showed itself.

I have had under my care a case with exactly the same history, and the location of the initial lesion was so unusual that several prominent rhinologists of this city failed to make a diagnosis. As the patient himself, who is a physician, asked me to publish his case for the benefit of others, I shall now report it.

———, M. D., thirty-two years of age, has always enjoyed perfect health until a few weeks ago, when he commenced to feel a dryness in his nose. It was very difficult for him to breathe during the night. The throat commenced to swell at the same time. One morning he noticed a small "sore" on the right side of his sæptum narium. During the day he had no difficulty in breathing, viz., when he was out attending to his practice, but when

he returned to his steam-heated apartment, he noticed very soon that breathing became difficult. He consulted a nose specialist in this city, who gave him a spray that did not relieve him at all. He used some ointment, on his own judgment, but without any relief. The symptoms gradually becoming worse, after having seen several other specialists he came to me for advice. He complained of frontal headache, and the other symptoms already mentioned. When he was in his apartment for any length of time his nose closed up and he had to syringe it. At night time he had to get up three or four times in order to moisten his nose, which was extremely dry, but nothing helped him. About one month after his trouble commenced he observed that the occipital glands of the right side and those on top of the head began to swell and ache severely. The patient did not suffer from influenza, although he called on me just at the time when it was endemic in this city. Although he had some fever and chills, these passed away very quickly. It is peculiar that during that same winter I had had occasion to notice glandular swellings on the top of the head in several cases of influenza affecting the upper air-passages or the ear. This symptom, together with the fever, made me believe that I had to deal with the sequelæ of a case of genuine influenza, in spite of the fact that Dr. X. himself previously did not believe it. The trouble in his nose I attributed to an extremely dry condition of his mucous membrane. Just at the locus *Kiesselbachii* there was a small sore that looked exactly like the beginning of a perforating ulcer of the sæptum, which I had seen develop quite frequently in consequence of picking the nose with the finger; and, moreover, the doctor had this habit. There was a whole chain of swollen glands on the right side, extending from the frontal bone down to the neck. I made the usual applications and ordered the usual hygienic measures, expecting the ulcer to heal within a short time. But instead of this it grew larger, although the doctor positively denied having picked his nose again. Now the glands on the other (left) side commenced to swell, the erosion became an outspoken ulcer, the submaxillary glands of the right side became involved, and, finally, the ulcer presented the characteristic appearance of a specific ulceration with its edges elevated above the level of the mucous membrane. The diagnosis was no longer doubtful to me, but the situation rather embarrassing, as the doctor had been happily married six months previously. Still, when I told him my idea of the nature of his trouble he remembered having examined *per vaginam*, in a dispensary some time ago, a woman who afterward proved to be syphilitic. Undoubtedly, while discussing this case with some other colleague, he picked his nose unconsciously with his finger, having forgotten to wash his hands first, and thus inoculated the dangerous virus into his own system. Very soon the secondary eruptions appeared over the entire body, the disease running its usual, and in this case favorable, course. Lately, *i. e.*, two years after the occurrence of the infection, when I saw him again there had not been any symptoms for about a year.

In going over this case we observe that here, as well as in other cases of extragenital chancres, the diagnosis was not easily made. In the first place, the chain of swollen glands did not direct attention toward syphilis. As I have remarked before, the patient became sick at a time when influenza was endemic. During that very period I had seen several such instances in which the

glands behind the ear and on top of the head were swollen. As in the above case the first symptoms were fever and swelling of these glands, I naturally attributed both to *la grippe*. It was not until later that the affection of the submaxillary glands, which by Pospelow and the other authors is considered pathognomonic, took place. None of these writers, however, mentions any swelling of the glands of the vertex and the occipital glands, not even in those cases in which primary lesions in the upper parts of the nose (middle turbinated) are reported.

Another factor that made the diagnosis difficult was the location of the ulcer on the sæptum, and at just such a place where the so-called (Votolini) *ulcus sæpti nasi perforans* usually occurs. We have to enter a little more into detail regarding these latter ulcerations, as they are of the greatest importance to us in this connection. We know that perforations of the sæptum narium are not necessarily always of specific origin, as was formerly believed. They are often only the result of boring the nose with the finger, or picking with the fingernail. This causes bleeding, excoriations, and ulcerations, which may heal in any stage, or finally go on to perforation.

Now, why do people pick the nose with the finger? The answer to this question is very simple. As a rule, they suffer from a dry rhinitis, with formation of crusts, and in the effort to get rid of these they make use of the finger. Permit me to quote from a paper of mine, published in 1891, a very interesting case belonging to this category:

"Henry L., a carpenter, sixty-five years of age, German, was attacked about seven years ago with pains in the left supraorbital region, which grew worse steadily. They extended toward the nose, and along its left side, and gradually spread over the whole left side of the face. The chief pain was in the region of the canine fossa and the ala nasi, and inside of the gums along the upper jaw. It is evident that we had to deal here with an infraorbital neuralgia. With these complaints he consulted me about two years ago. He is a most nervous and excitable fellow, working constantly with his fingers in or on the nose, and in such a comical way that one can hardly suppress laughter. As described by him, "it itches and tickles, and stings inside," so much that he cannot sleep on account of it. For this reason he could not follow his vocation as a carpenter. He had an atrophic rhinitis and a slight hypertrophy of the left lower turbinal. This was cauterized, but without the least result. The patient soon disappeared. A year ago he returned with exactly the same symptoms, only to disappear again after a short time. About a month ago he returned for the third time, and I was not a little surprised when on examination I found a complete perforation of the cartilaginous sæptum. It was oval in shape and directed toward the right, and from below upward. The opening was larger on the left side than on the right. The mucous membrane on the borders was very thin and smooth—no ulceration. I asked myself whence this perforation came. I naturally thought of syphilis, and gave the patient large doses of potassium iodide, although absolutely no other symptoms were present. But no improvement followed. Inunctions had the same negative

result. As, moreover, tuberculosis was not present, I had to come to the conclusion that I had to deal here with a genuine case of perforating ulcer of the *sæptum narium*. The patient picked his nose constantly, thus producing an abrasion which, in the course of a year, became an ulcer, and then gradually, in the manner described above, the perforation we have now before us. I should like to mention as characteristic, the peculiar oval defect just in the direction in which he inserted his finger; furthermore, the thinness of the mucous membrane around the perforation, and, finally, the absence of any pathological change in the neighboring parts."

To return to our colleague, he had similar symptoms at the commencement of his trouble. He had a very dry rhinitis, and he had the beginning of a perforating ulcer. This ulcer showed surely no signs of syphilis in the first weeks. It looked very clean, because the doctor sprayed his nose, inhaled, or bathed it almost constantly. Not until later, when the induration appeared in connection with glandular swellings, was the case clear. No doubt, the doctor was in the habit of picking his nose, and the shape of the ulcer reminded me very much of the case of the carpenter cited above. Perhaps, with his atrophic rhinitis as a persistent cause, the doctor would have developed, sooner or later, a perforating ulcer of the *sæptum* of the nose, but, naturally, not specific in nature.

There is one point more which I should like to mention briefly, viz., Must a lesion of the epithelial layer be necessarily present before a syphilitic infection can take place? It seems that this is not always essential. Most of the cases of extragenital chancres occur in and around the mouth, and in many instances a lesion has not been found at all. We have an analogy in the tuberculous virus. As has been shown by several observers, the tubercle bacilli can penetrate the intact mucous membrane, but the difference in the development of the two infections is very marked. In Wood's cases, cited above, a healthy man struck a syphilitic person on the mouth "hardly enough to draw blood," and developed syphilis. This would never take place in tuberculosis, where the individual must have a *locus minoris resistentiæ*, in order to favor the development of the infectious or contagious virus. "The virus of syphilis," on the other hand, "is one of the most energetic and certain of animal contagions, and exerts its power whenever and wherever it can find a suitable opportunity" (Bulkley).

There are undoubtedly many more cases in which physicians have acquired syphilis in a similar manner, as above stated, but for obvious reasons only few of these are reported. If physicians would remember that they should use ordinary precautions against infection, not only for the sake of their patients, but for their own sakes, such unfortunate accidents could be entirely prevented.

Since writing this paper an interesting article has appeared, by Sendziak, of Warsaw (Ueber luetischen Primäraffekt in der Mund- und Rachenhöhle, so wie in der Nase und den Ohren. *Monatsschrift für Ohren-*

heilkunde, 1900, p. 419), to which I would refer for further statistics.

1003 MADISON AVENUE.

SYPHILIS OF THE NERVOUS SYSTEM.*

By B. ONUF (ONUFROWICZ), M. D.,

BROOKLYN,

NEUROLOGIST TO ST. CATHERINE'S HOSPITAL, ETC.

AMONG the manifestations of syphilis, those affecting the nervous system, and particularly the brain and spinal cord, are by no means infrequent. They occur sufficiently often to require the serious attention of the general practitioner, who may often be confronted with them in so marked a form that he is entirely at a loss how to interpret them. Some familiarity with the symptomatology of cerebrospinal syphilis, so called, is therefore essential, especially since the recognition of the disease may enable us to obtain gratifying therapeutic results in apparently desperate and irremediable cases. It is true that these sometimes brilliant therapeutic results are not always of long duration, the tendency to relapse being quite marked in many cases, but this should not prevent us from striving to do all we can. Oftentimes the relief given by appropriate treatment is so great that this alone should make it worth while to use our best efforts, which are commonly rewarded by gratitude on the part of the patient.

We know how difficult it frequently is to get a definite history of past syphilitic affection. In some cases a chancre was present, but no secondary manifestations appeared, making it thus doubtful whether the chancre was of a syphilitic or non-syphilitic nature. In other cases, again, the secondary symptoms may have passed unnoticed. Or the primary affection may have such a

*Read before the Brooklyn Medical Society, also before the Kings County Medical Association.

bizarre or uncommon location that it is unnoticed or misinterpreted. I remind you in this respect of the concealed chancre in the urethra simulating gonorrhœa, and also of primary chancre of the vaginal portion of the cervix; furthermore, you are acquainted with the occasional chancre of the lips and the chancres of the fingers to which physicians and especially surgeons frequently fall victims. Finally, the patient may be in a comatose or delirious condition, or be otherwise mentally deranged and unable to give a history.

Keeping all these points in view, it is evidently very important to obtain guiding lines which may enable us, in a given case, to diagnose syphilitic disease of the nervous system independently of a history of syphilitic infection.

DIRECT SIGNS.—In looking for such guiding lines we must bear in mind, in the first place, that syphilis is a constitutional disease, a general infection. Its manifestations are therefore not confined to a single part of the body or any single organ, but are scattered here and there over the whole organism, affecting one part more, another less. Some of these manifestations disappear, leaving hardly a trace, if any; others leave lasting changes, such as scars, gummata, etc. Consequently one of our guiding lines would be the presence in the organism of changes pointing in a more or less definite manner to a past syphilitic affection. Among these changes we shall have to consider those of the skin, the mucous membranes, the eyes, the heart and blood-vessels, and the internal organs. It is not the purpose of this paper to enter upon all these signs in detail; only those which are of particular diagnostic importance will be mentioned.

The Cutaneous Manifestations.—The external genital organs ought to be first thought of. The presence of a scar of the præputium or labia, etc., should arouse our suspicion; but, while the presence of such a scar or scars is of much positive value, although not a definite proof of syphilitic affection, its apparent absence should not be relied upon as speaking against syphilis, since the primary chancre may leave so little of a scar as to escape detection; moreover, as has been pointed out already, the primary affection may have been located elsewhere.

Among the other cutaneous affections, we have to distinguish fresh, or florid, manifestations and, secondly, the old ones, that is, evidences of a past process. The fresh ones when found are, of course, of great value, their syphilitic nature being recognized either by their character (for instance, a roseola or a papular exanthema) or by their clinical course, especially under anti-syphilitic treatment.

However, in cases of cerebrospinal syphilis it seldom falls to our lot to meet with fresh affections, which occur mostly in an earlier stage, and we must therefore rely more upon evidences of past affections, principally cutaneous scars. The secondary cutaneous syphilitic eruptions, such as the roseolar and papular, usually leave no scar, but the tertiary ones, such as ethyma, rupia, etc.,

leave scars which are rather characteristic. It is the flat, slightly sunk in or somewhat scooped out white scar which, if found in considerable number, and especially if of symmetrical distribution, is typical of past syphilis. The multiple small scars found on the forearm of blacksmiths will hardly be mistaken for syphilitic scars. Scars from small-pox are also very unlikely to be mistaken for syphilitic ones, being usually much smaller, deeper, and more irregular, and frequently pigmented.

Loss of hair is another important sign and can hardly be mistaken for alopecia areata, in which the areated distribution of the hairless regions is so typical that the two can certainly be distinguished.

As to the manifestations on the part of the mucous membranes, I would call special attention to the importance of examining the pharynx and often also the larynx. While mucous patches are seldom encountered at the stage when organic cerebrospinal syphilis occurs, we may find a gumma of the soft palate or a syphilitic perichondritis of the larynx, or an old stellate scar of the soft palate or larynx. An examination of the rectum, vagina, and uterus may disclose similar manifestations. In one of my cases the diagnosis of cerebral syphilis was corroborated by finding a large white scar of the soft palate and uvula. The autopsy revealed the presence of gummata in the brain. In this case one physician expressed great astonishment at my diagnosis. Had he looked at the soft palate, he might easily have made the diagnosis.

Manifestations on the Part of the Eye.—These may often be of great importance. The presence of a fresh iritis, especially of a fresh plastic iritis, which is almost characteristic of syphilis, or the discovery of adhesions of the iris, pointing to a past iritis, are of great diagnostic help, although they are frequently missing. The pupillary changes caused by old adhesions ought not to be confounded with those pupillary changes which are due to faulty innervation, of which I shall speak later. I mention also interstitial keratitis, very frequently of syphilitic origin.

Ophthalmoscopic examination may lead to the discovery in the fundus of the eye of vascular changes which may give very valuable clues, such as an obliterating endarteritis, or tortuosity of the arteries, or hæmorrhages. In one case which Dr. Coffin saw with me, these three changes were very marked, and Dr. Coffin said that the shape of the hæmorrhages, which were small and wedge-shaped, was almost characteristic of the disease. In that case there was also marked optic neuritis, a symptom which, although found in a great many other affections, yet may often serve to confirm the diagnosis if other symptoms point to a syphilitic brain disease.

Syphilitic Symptoms on the Part of the Heart.—Of these, I wish to point out the tachycardia and the irregularity of the heart's action, often met with, either combined or one alone, and both probably the expression of a syphilitic affection of the myocardium.

Vascular Changes.—On the part of the vascular sys-

tem I have already pointed out the obliterating endarteritis that we may encounter in the blood-vessels of the retina, but other blood-vessels may also be diseased, and I remember one case, in particular, in which the radial arteries were so tortuous and thickened that they could be seized and rolled between the fingers, and yet they lacked the stiffness which is found in advanced senile arteriosclerosis.

The condition of the arteries of the foot may also be of great value in this respect, as those arteries may have the same character as I have described for the radial one. Such arterial changes will prove especially important if found in a person under forty and showing no other cause for arterial degeneration, such as alcoholism, the morphine habit, lead poisoning, or Bright's disease.

Internal Organs.—Of the syphilitic changes of the internal organs, I shall say only that we may have syphilitic pulmonary changes, manifested frequently under the picture of a bronchitis or of incipient phthisis, or there may be alterations in the shape of the liver, especially retractions of the surface or margin, which are pretty characteristic of syphilis, and combined with this we may find enlargement of the spleen.

I have repeatedly been asked the following questions, which possibly should be discussed at this juncture: What does it prove for the brain or spinal cord if we find syphilitic changes in the skin or heart or other parts? May not a syphilitic person present brain symptoms referable to a quite different cause than syphilis? Of course he may, and the possibility must be kept in mind. Nevertheless, it would be wrong to underestimate the value of evidences of syphilis in other parts of the body as a diagnostic aid to the recognition of syphilis of the brain or nervous system in general. We know that in medicine everything is relative, and while a symptom may attain great diagnostic value in combination with others, it may have very little significance as a symptom *per se*. I remind you of the enlargement of the spleen which may greatly help to establish the diagnosis of typhoid fever, yet, considered by itself alone, would be of little diagnostic aid, being met with in a great many other conditions. So it is the concurrence of symptoms, the *ensemble*, that we must rely upon much more than upon one single fact. And if this is considered in this light, we may easily appreciate the diagnostic importance of the discovery of syphilitic changes in other parts of the body in the diagnosis of syphilis of the nervous system, if in addition to these syphilitic manifestations in *other parts* we find a clinical complex and course of *nervous symptoms* that are characteristic or suggestive of syphilis.

We shall now pass to a consideration of the symptoms of syphilis referable to the nervous system, and see what characteristics may be found in the clinical course, quality, and combination of such symptoms to enable us to make the diagnosis of the disease mentioned.

General Course of the Nervous Symptoms.—The dis-

inction between secondary and tertiary symptoms usually made may to a great extent be applied also to syphilis of the nervous system. We speak, moreover, of *meta-syphilitic* diseases, such as locomotor ataxy and general progressive paresis, which cannot be called syphilitic diseases in the proper sense, as their clinical picture and course differ essentially from those of the syphilitic lesions. They are degenerative diseases, so called, and the syphilis forms only the basis on which they develop. It is not the purpose of this paper to dwell upon this class of diseases.

As to the nervous symptoms of the secondary stage of syphilis, you are probably all well acquainted with them. The chief triad is headache, insomnia, and loss of hair. Whether the loss of hair is really a nervous symptom may be a matter of some doubt, although it probably is. These nervous symptoms of the secondary stage distinguish themselves from those of the later stages by their comparatively short duration and usually also their comparative mildness. They appear more like the expressions of some toxic state than of inflammatory focal lesions such as are encountered in the later period. They belong more to the domain of the general practitioner than to that of the neurologist, who seldom meets them. However, occasionally cases occur in which the nervous symptoms acquire a grave character pointing to extensive focal lesions of the brain or spinal cord at a very early period.

An instance of this is the following case, which, in order not to tire your patience, I report in a much abbreviated form: The patient was sent to me by Dr. Dillon, who had treated her for specific disease and rightly suspected some syphilitic affection of the brain.

Mrs. M. W., twenty-four years old, of American nationality, gives the following family history: Father died at age of about forty years, of a paralytic stroke. A sister of the patient has for seven years been hemiplegic. This is interesting as showing the hereditary tendency to organic brain affection. Of the patient's own history, I omit the earlier data as unessential. In February, 1899, she got married, but left her husband in April of the same year, and had never approached him since. It is in that period, between February and April, 1899, that the syphilitic infection must have taken place; at least the patient denied any other possibility.

In the beginning of September, 1899, she felt swollen in the region of the labia, but consulted no physician then. About the 20th of September an exanthema, evidently a roseola, appeared, coming and going and lasting three weeks altogether. At that time she had also headache, loss of hair, and sores in the mouth. From the end of September until the earlier part of October her limbs and back felt very weak and painful. In December open sores appeared round the corner of the mouth, and the palms of the hands were dry and scaly.

In January, 1900, she had an affection of the labia, hard lumps underneath the flesh as she expressed it. She had then another period of headache lasting about a month, the pain being occipital, coming on daily in attacks of about two hours' duration. She had again headache from March till the middle of May, almost con-

stantly, then again during a week in June, and finally again from July 25th until August 19th, when she first came under my observation, so that she had had five periods of headache altogether. The last headache attack was very severe; nothing seemed to relieve it. About August 1st her gait began to be unsteady and staggering.

When I examined her, on August 19th, I found a very staggering gait, distinct ataxy of the right upper limb, and marked exaggeration of the knee-jerks. The occipital region corresponding apparently to the exit of the occipital nerve was tender, but the skull was not painful on percussion. Ophthalmoscopic examination revealed no changes in the fundus, as was confirmed by Dr. Smith.

The symptom-complex found pointed mostly to a cerebellar affection, in favor of which spoke also the absence of any symptoms on the part of the cranial nerves, except that hearing was diminished on the right side. The syphilitic nature of the brain lesion, presumably a gumma, was made very probable by the history and was confirmed by the result of the antisyphilitic treatment, consisting mostly in mercurial inunction, under which the patient improved quite rapidly, the headache, the disturbance of gait, the ataxy of the right upper limb, and the exaggeration of the reflexes disappearing almost entirely within about four weeks.

In this case I made a special point of ascertaining the date of the infection, which apparently took place from sixteen to nineteen months previous to the onset of the grave brain symptoms. But even if we disregard the patient's assertion that the infection could only have taken place between February and April, 1899, the onset of the focal organic brain lesion within ten or eleven months after the appearance of the roseola clearly shows at what early stage of the disease grave organic changes of the brain may occur. Usually, however, they appear much later, sometimes within three or four, sometimes within ten or twenty years after the infection, although in these very late cases I always feel some doubt as to the correctness of the given date of infection, unless the history seems to indicate the presence of syphilis through all these years by the appearance at longer or shorter intervals of symptoms of the disease.

This leads me to speak of one of the general characteristics of syphilis, namely, its occurrence in attacks of active manifestations alternating with periods of comparative dormancy. On the whole, as the disease progresses, both the dormant intervals and the periods of active manifestations become longer and the symptoms become more severe and more obstinate to treatment. This paroxysmal course applies also to the syphilitic lesions of the nervous system and may help us greatly in establishing the diagnosis. But let me add here that another disease shows this characteristic of paroxysmal development, namely, disseminated sclerosis of the brain and spinal cord. This malady resembles cerebrospinal syphilis also in many other respects, making it frequently quite difficult to distinguish them.

Another characteristic of syphilis, and quite particularly of syphilis of the nervous system, is that, on the whole, its symptoms not only respond to treatment in a

high measure, but often recede also to a great extent without medication. In one case under my observation a hemiplegia which had been in existence for several months disappeared almost entirely within one or two days, after the treatment with increasing doses of potassium iodide had been pushed up to the daily use of 600 drops of the fifty-per-cent. solution. This case had been accompanied by headache, vomiting, choked disk, a compression pulse, extreme somnolence, and other symptoms suggestive of cerebral tumor, but the almost complete disappearance following specific treatment proved the syphilitic nature of the disease. As in the case mentioned, so in others, the disappearance of a focal symptom, for instance of a paralysis, is often so rapid and complete that it reminds one much of hysterical paralysis or of other hysterical phenomena, which also may disappear all at once after long duration.

While a paralysis of other organic origin, say a hemiplegia from embolism, for instance, or a paralysis from acute anterior poliomyelitis, may also recede quite considerably, yet one seldom sees such a complete restoration of function after paralysis from organic disease as is seen in the syphilitic cases. I do not imply thereby, however, that all syphilitic lesions of the nervous system are so evidently amenable to treatment, but wish, on the contrary, to call your attention to the fact, justly emphasized by Eskridge in a recent article, that sometimes the nature of the damage is such as to make complete repair impossible. If, for instance, owing to an obliterating syphilitic endarteritis, a blood-vessel becomes entirely obstructed, the effect will be the same as in thrombosis, namely, an irreparable softening focus, unless a collateral circulation can be established.

Closely allied to the great responsiveness to medication, which, as we have seen, has its exceptions, is another feature of syphilis, namely, the great variability of the clinical picture. The symptoms are subject to great change; one may go, while a new one comes, etc. That this variability is especially marked in syphilis of the nervous system, particularly of the brain and spinal cord, is explained by the complexity of these organs, owing to which fact disease of one point of the brain or cord responds with quite other symptoms than that of some other part of the same.

In this point, again, I mean in this variability, there is a great similarity to hysteria, which, as a rule, also presents this characteristic.

After this general outline, I shall now consider under what forms cerebrospinal syphilis may occur, and may then discuss the diagnostic value of some particular symptoms.

1. *Meningitis*.—Frequently cerebral syphilis occurs in the form of a meningitis, which is usually basal. If so, we recognize it by the affection of cranial nerves and the optic neuritis, which will point to the seat of the lesion.

One distinguishing feature from other forms of

meningitis, from the tuberculous variety, for instance, is the fact that in the latter the palsies of the cranial nerves usually appear at a late stage, when coma has already developed, while in syphilitic meningitis they may make their appearance quite early. In the other forms they are mostly bilateral; in syphilis they frequently are unilateral and may affect but one single cranial nerve. I will mention at this place that palsies of single cranial nerves are rather typical of syphilis.

As to the optic neuritis, or choked disk, so called, it is found in all forms of meningitis, but in the syphilitic variety the accompanying vascular and other changes of the eye to which I have called attention may help us out.

2. *Tumor*.—I have already briefly pointed out a case in which the syphilitic cerebral manifestations were those of cerebral tumor, and a case reported in this paper was of a similar kind. To recognize the particular syphilitic nature of a gumma which may also be called a tumor, an exact history and thorough general examination are often essential.

3. *Multiple Focal Affection of the Cerebrospinal Axis*.—If syphilis occurs in the form of multiple foci or patches, distributed over the brain and spinal cord, it may closely resemble disseminated cerebrospinal sclerosis. In one case which I have alluded to in this paper there was a very typical intentional tremor, such as is described as characteristic of multiple sclerosis. The distinction between the two diseases is frequently quite difficult, especially because in multiple or disseminated sclerosis also very marked remissions may occur. And here, again, I think diagnostic salvation lies in a thorough general examination, which may reveal the presence of lesions pointing distinctly to a syphilitic affection.

The presence of pupillary changes, for instance, small size, or irregular shape, or deficient response of the pupils, would speak in favor of syphilis as against multiple sclerosis, in which latter pupillary changes are the exception.

Heretofore the rare occurrence of optic neuritis in multiple sclerosis has been emphasized, but this has been shown to be erroneous by the recent clinical researches of Bruns and Stoelting, who found optic neuritis present in a great percentage of cases of disseminated sclerosis. Therefore the presence or absence of optic neuritis cannot well be used for distinguishing between the two diseases.

One sign that seems pretty reliable is the typical facial expression of multiple sclerosis, the exaggerated mimicry in this disease, which so far I have not observed yet in syphilitic cases.

4. *Hemiplegia*.—This is a form under which syphilis is met with pretty often. It may set in with the relative rapidity of a thrombosis or embolism, or may develop slowly. If not due to a vascular obstruction, leading to a permanent softening on account of cutting off of the blood supply, it may yield enormously to antisyphilitic treatment and disappear almost without leaving a trace.

I had recently occasion to treat a patient at the Polhemus Clinic who had had two attacks of hemiplegia, one on the left, the other on the right side. The first one, that of the right side, set in pretty suddenly, without loss of consciousness, about three years ago, and disappeared almost entirely. The second one came on suddenly, in February of this year, and the patient came under my observation about two months after its onset, when he presented the typical aspect of a hemiplegia of the left side, with marked contractures and exaggeration of the deep reflexes. He was put under specific treatment, namely, with increasing doses of iodide of potassium, and within about two or three months marked improvement began to take place. When I saw the patient a few days ago, the hemiplegia was practically entirely gone. This case is of so much interest as the diagnosis was made by Dr. McGoldrick and myself, each independently, he having been consulted by the patient on account of a persistent cough, and the doctor then discovering a heart lesion the syphilitic nature of which he promptly recognized.

5. *Diffuse Brain Lesions Simulating General Progressive Paresis*.—I have met with some cases in which the mental and some of the neural symptoms were those of general progressive paresis, there being mental enfeeblement, lack of mental concentration, loss of memory, typical speech disturbance, loss of pupillary reaction to light, fibrillary twitchings of the face, etc. But the presence of certain other symptoms, and especially of marked focal manifestations, spoke against general progressive paresis in the proper sense and in favor of syphilis. I mention almost complete unilateral paralysis of the third nerve with vomiting setting in acutely, and a spastic ataxic gait, as I have seen it in one case. I have, unfortunately, not been able to follow this case, but have heard that the man improved greatly and that the extreme ptosis which he had had disappeared.

Since general progressive paresis, although not a really syphilitic disease, very often develops on a syphilitic basis, it may frequently become difficult to decide whether we have to deal with a really syphilitic disease, simulating general progressive paralysis, or with general progressive paralysis in the proper sense.

SPINAL CORD DISEASES.

6. *Pseudo-tabes, or Syphilitic Tabes*.—The typical tabes, or locomotor ataxia, so called, although developing mostly in individuals who long years back were infected with syphilis, is yet not really syphilitic, but a degenerative disease, and usually is very little influenced by antisyphilitic treatment. There are cases, however, which improve quite considerably under antisyphilitic medication, and I am personally inclined to consider such cases as having a different anatomical basis, being probably due to a syphilitic inflammation of the meninges. Their really syphilitic nature is made very probable also by the relatively much earlier onset, sometimes two or three

years after the infection, while common locomotor ataxy usually develops as late as from ten to twenty years after the syphilitic infection.

7. *Spastic Paraplegia*.—Syphilis of the spinal cord often takes also the form of spastic paraplegia, being as a rule distinguishable from the non-syphilitic type of this disease by the presence of sensory disturbances or disorders in the function of the bladder or rectum, and of pupillary changes, all of which are wanting in typical spastic paraplegia.

8. *Anterior Poliomyelitis*.—If affecting the anterior horns, syphilitic disease of the spinal cord may closely resemble anterior poliomyelitis, and the differential diagnosis would have to be made by the presence or absence of other lesions pointing to syphilis of the nervous system or other parts, and by the result of the specific treatment.

9. *Syringomyelia*.—Although I have not seen a case of syphilis that simulated syringomyelia, a disease characterized by the formation of cavities in the spinal cord, I yet believe that such cases might occur. They would be apt to react to antisyphilitic medication, while actual syringomyelia would not, at least not to any extent.

PERIPHERAL NERVES.

10. *Diseases of the Peripheral Nerves*.—The occurrence of actual neuritis is denied by most authors, and it is thought that when a nerve becomes affected in syphilis this is due to disease of the surrounding tissue involving the nerve directly or indirectly. So we may have a paralysis of a cranial nerve, either from inflammation of the meninges or from inflammation of the periosteum at the places where the nerve passes through or near these structures.

SPECIAL CHARACTERISTICS OF CEREBROSPINAL SYPHILIS.

In concluding the symptomatological discussion, let us ask whether there are any symptoms typical of cerebrospinal syphilis. We may answer, There are some, although none is absolutely pathognomonic.

Paralysis of single cranial nerves, as has been said already, is pretty characteristic, especially that of the ocular nerves. Recently Sachs has pointed out the irregular shape of the pupils, and especially the irregular manner of contraction of the pupils, in cases of cerebrospinal syphilis, and believes it to be characteristic of that malady. There is no doubt that we frequently meet with it in this disease, but it is also observed quite commonly in general progressive paralysis and sometimes in locomotor ataxy. Although important enough, diagnostically, I do not believe, therefore, that this irregular shape of the pupil is so typical of syphilis as Sachs seems to think. I think that another pupillary sign, namely, the very contracted, or pin-head, pupil is perhaps more characteristic of syphilis than the irregularly shaped pupil.

Vertigo is a sign which ought to make us suspicious of cerebral syphilis, although we know that it is seen in quite a number of other conditions, such as arteriosclerosis, labyrinthine disease, anæmia, etc.

The differential diagnosis has been so far discussed in this paper that I need not enter upon it any more. I shall only repeat here that, while the effect of antisyphilitic treatment is of great confirmatory value if positive, it does not absolutely speak against syphilis if negative.

PROGNOSIS.—I am not prepared to give you any statistical data on the prognosis of cerebrospinal syphilis. My personal experience has been that the single attack of active manifestations, as a rule, proceeds favorably if proper treatment is applied, but the chances of ultimate recovery are not very bright, as the tendency to relapses seems quite marked. That in cases of vascular obstruction from syphilitic endarteritis a permanent and extensive incurable damage may result has been mentioned already.

TREATMENT.—As you know, the two sovereign remedies in the treatment of syphilis are mercury and potassium iodide. These you will find also serviceable for combating specific disease of the nervous system. As to the choice between the two, the prevalent idea is that mercury is of special value in the secondary and iodide of potassium in the tertiary period. But I believe that Eskridge's view is more correct, that mercury is especially efficacious in the acute and potassium iodide in the chronic manifestations. It is true that this view coincides to a great extent with the one first mentioned, inasmuch as, on the whole, the secondary manifestations are acute and the tertiary ones chronic; but there are very marked exceptions to this rule, and therefore Eskridge's advice holds good. However, no cast-iron rule can be made here, and often the respective value of each of these remedies has to be tested in the individual case. But I cannot omit emphasizing one point, and this is, that failure to obtain any therapeutic results is frequently due to the fact that the medication is not pushed up to a sufficient degree. This has special reference to the iodide of potassium, which in small doses often remains without effect. The wisest plan is usually to begin with small doses and increase rapidly until a physiological effect is reached. For instance, one begins with 5 drops of the saturated aqueous solution in the morning, 10 drops at noon, 15 drops in the evening, and thus goes on increasing five drops with each dose. In so doing one frequently discovers an enormous tolerance of this drug, from 500 to 600 drops daily being many times borne without inconvenience for long periods, and often the therapeutic effect begins only after such a high dose as the one mentioned is reached.

The mercury is best given in the form of inunctions, a drachm or a drachm and a half of the strong mercurial ointment to be rubbed in daily in two sittings. Injections of corrosive sublimate frequently act more promptly and make it possible to keep the patient under obser-

vation, but are often objected to by the latter. A thirtieth or a twentieth of a grain may be used to begin with. The medication must be frequently continued for months, but should at times be discontinued and a general tonic treatment substituted. Hot-air baths or vapor baths to stimulate metabolism may be very useful.

ACUTE STRANGULATED FEMORAL HERNIA ON A PUERTO RICAN HILLSIDE.

By P. R. EGAN,
SURGEON, U. S. ARMY.

ON May 10, 1899, when out in an ambulance inspecting the work of the corps of vaccinators employed in various towns of the district of Guayama, my colored driver went into the brush at the top of the hill, about seven miles from Caguas. While there, he developed *de novo* an acute strangulated femoral hernia of the right side. I was without instruments or medicines of any kind. The driver returned bathed in perspiration, complaining of being ill and nauseated, and requested that I leave him on the roadside in the boiling tropical sun, so that he might die easily. The tumor was found to be about the size of the closed hand. He was placed on his back on the floor of the ambulance and an attempt made then and there to reduce the strangulation by taxis. This only failed of success because of his restlessness under the great suffering that he endured. I finally desisted when he declared that he could not stand any more pain and that he knew it was going to kill him, anyhow.

The prospect was not very inviting. I was alone with a very sick man, at the head of a steep hill, zigzagging for about five miles, and bordered by a couple of steep ravines, with an ambulance without a proper brake, and four mules that I did not know how to handle. But there was no alternative. Proceeding very slowly, I was fortunate enough to reach Caguas, and was driving to the house of the English-speaking doctor, when a native cart crossing in front of my mules turned them up a side street, out of which I could not guide them. Leaving the mules and patient in charge of a native boy, I proceeded on foot to the doctor's house. There I learned that there was no such thing as a hospital in that fourth or fifth largest city on the island. Procuring some chloroform, I returned with the doctor to the ambulance. Some natives had very charitably taken him into one of their wretched houses and placed him on a cot.

The tumor was now as large as an infant's head, tense, and of a purplish color. He was covered with cold sweat, and had twice vomited. Under chloroform the doctor tried taxis and gave it up. After about half an hour I was fortunate enough to reduce it. I was also lucky enough to find a truss in the town, which I fitted to him. Inside of an hour he was outside, driving his mules on the road to Aguas Buenas, very much dazed

and wondering what it all meant, but free from pain or ache.

From a surgical point of view I know that taxis was maintained too long. But under the circumstances it appeared to me to be, as the result proved it to be, his only salvation. There never was a doubt in my mind that an operation, with his surroundings, meant sure death. So I persisted.

Twelve months afterward he came to see me. He had got a new truss, which supported his hernia perfectly. He had no trouble in pursuing his employment as a government teamster. On the strength of my driving safely down the hill at Caguas he promised me a position as mule-driver in case I failed in my examination for promotion. I was delighted; grateful non-paying patients are such a rarity.

FORT DOUGLAS, UTAH.

Correspondence.

LETTER FROM TORONTO.

Small-pox in Ontario.—The Samaritan Hospital, Montreal.—The Health Officer of Hamilton.—Severe Punishment for Failure to Pay Assessments in Ontario.—The Victoria Asylum for Women.—The Toronto Clinical Society.—An Enterprising Cripple.

TORONTO, May 4, 1901.

DR. THOMAS HENRY LITTLE, of this city, died on the morning of the 25th of April of hæmorrhagic confluent small-pox. About ten days prior to his death Dr. Little was summoned to attend a young man, lately arrived from Cleveland, but failed to recognize his malady as small-pox. A case developed in a neighbor's child, which was immediately ascertained to be small-pox by Dr. N. A. Powell, and the child was sent to the isolation small-pox hospital. In searching for the source of infection, Dr. Little's patient was found, and the medical health officer, Dr. Sheard, who was away on his annual holiday in New York, was summoned home. Dr. Little then contracted the disease and was forthwith removed to the pest-house, where he died eight days later. At the time of his death the statement was made that he had never been vaccinated, but this has since been denied by his friends. Dr. Little was thirty-nine years of age and a graduate of Victoria and Toronto universities. He had practised twelve years in this city.

The small-pox situation throughout the Province of Ontario, which two weeks ago was considered to be abating, is as yet far from satisfactory. Within the last few days new centres have been discovered and the disease has appeared among the Indians on the reserve along the Grand River below Brantford. The latest returns show that there have been forty centres and five hundred cases, of which only six have terminated fatally. Up north, in New Ontario, some five thousand people have

passed through official hands on the trains, most of whom were vaccinated. Dr. Bryce, the provincial health officer, has given out figures which will not be palatable reading to the opponents of vaccination. In the late outbreak at Toronto Junction, all who had been vaccinated escaped with but one exception, while, on the other hand, none of those who were attacked by the disease had been vaccinated, but one person, who had a very mild attack. Dr. Bryce thinks Toronto will run considerable danger during the coming summer from tourists from the Pan-American Exposition, and therefore counsels a general vaccination.

The annual report of the Samaritan Hospital, Montreal, shows that during the past year there were 110 indoor patients, with a total number of 2,125 days in the institution. Altogether there were 142 operations. Only five deaths occurred, and three of these followed on operations, which gives a death rate of a little over two per cent. In addition to the foregoing there were 250 out-door patients. At the present time every bed of the hospital is occupied. Dr. A. Laphorn Smith presented the annual report, he being surgeon-in-chief and superintendent of this institution. This hospital admits only women of irreproachable character who may require medical treatment peculiar to their sex. At the present time there is a large number of suitable young ladies waiting to be trained as nurses, but until a larger building is obtained it will be impossible to increase their number.

The city of Hamilton has recently had some little trouble over the appointment of a medical health officer for that place. Finally one was appointed at the munificent salary of \$1,000, although there were many applications for the position at \$800. The duties of this officer will be by no means limited, as the by-law setting forth what will be required of him shows. In addition to discharging such duties as are required by the Health Act, he must devote his whole time to his work, attend the inmates of the jail, look after any indigent persons who may chance to become sick, attend policemen and firemen, vaccinate, and do many other things. The multifarious duties of this position have brought forth an unusually brilliant idea from the *Bobycegeon Independent*, to the effect that every township and village might have its municipal doctor, and asking why, when a place of the size of Hamilton—Hamilton has a population of 60,000—can obtain one for such a trifling salary, every other city, town, or hamlet might not do likewise. The "thinker" on the editorial staff of the newspaper referred to has an idea that the present system of doctors is all wrong, very unwise, and most inequitable, and that it is high time the municipal doctor became an established fact.

On the 19th of April the Medical Council of the Province of Ontario sent out a circular letter to a large number of practising physicians throughout the Province advising them that their names had been erased from the register of the College of Physicians and Surgeons and

that, unless they paid up all assessments owing by them within thirty days, they would be proceeded against in the same manner as if they were irregular practitioners. In a medical population of 2,500 there were some seven hundred delinquents who had not paid the regular \$2 annual assessment for some years, but since the notice some one hundred of these have paid up. The remainder of the number sent a delegation the other day to wait on the government, asking that the Medical Council stay its hand and not create any trouble in the profession until such time as the matter could be amicably settled. Dr. Sangster, of Port Perry, himself a member of the Medical Council, headed the delegation, he having been the prime instigator in a similar movement some ten years ago to do away with this same fee. The Medical Council, the governing body of the Ontario College of Physicians and Surgeons, is composed of some thirty members, thirteen of whom are representatives from the medical colleges and from the homœopathic body; and a good many believe they have too much influence and that the profession is not properly represented. Matters will soon become pretty warm, as it is understood that the prosecutor for the council will, after the expiration of the month of grace, begin proceedings against those whose names have been erased from the rolls and who have not become reinstated.

The Victoria Asylum for Women, which is rapidly nearing completion and is situated in the town of Coburg, will be opened by the government about the 1st of September for the reception of patients. Dr. McNichol, of Coburg, has been appointed superintendent, and he is to have associated with him in his work a lady physician, Dr. Harriet Cockburn, of Toronto, the first female physician appointed to any similar position in this Province. Dr. McNichol is at present visiting the various asylums of the Province, to familiarize himself with his duties. Dr. Cockburn has had considerable hospital experience, having been connected for some time with the Dakota State Asylum for the Insane. The appointment was made in response to a demand made upon the government by the National Council of Women. Both physicians are highly recommended and well qualified for their work.

The Toronto Clinical Society held its last meeting of the 1900-1901 season on the evening of May 1st. Dr. H. A. Bruce presented a patient, a man twenty-four years old, who at the age of five years had had otitis media in the right ear. Six months ago he was taken with pain in the ear and an operation was advised. The mastoid was opened and pus found in the cells; moreover, from three to four ounces of pus were drawn from the temporosphenoidal lobe. The patient had very few symptoms except a slow pulse and depressed temperature with some vomiting. Ankle clonus and exaggerated knee-jerks were present. A good recovery was recorded. Dr. F. LeM. Grasett showed a fatty tumor taken from the thigh, just above the popliteal region. Considerable

difficulty had been experienced in separating it from the sciatic nerve. He also reported a case of duodenal ulcer. Dr. George A. Bingham told of an enterprising cripple, a lad of fourteen years, belonging to a northern town, twenty miles away, who, hearing of the good work performed at the Victoria Hospital for Sick Children, Toronto, decided, although he was without means, that he would get there somehow. He harnessed his dog to a sleigh and drove all the way to Toronto in the dead of winter. This lad, who was very much deformed from his knees down, was rewarded for his perseverance, as Dr. Bingham was able to benefit him considerably. The following officers were elected for the ensuing year: President, Dr. J. F. W. Ross; vice-president, Dr. E. E. King; treasurer, Dr. W. H. Pepler; recording secretary, Dr. George Elliott; corresponding secretary, Dr. A. A. Small; executive committee, Dr. H. J. Hamilton, Dr. H. B. Anderson, Dr. W. B. Thistle, Dr. H. A. Bruce, and Dr. George A. Bingham.

Therapeutical Notes.

To Remove Picric-acid Stains.—For those using picric-acid dressings the following solution for removing the stains of that drug, cited by *Arte medica* for April 7th, from the *Journal des praticiens*, and ascribed to Brynk, may be useful:

- R Boric acid. 20 parts;
- Sodium benzoate. 5 "
- Distilled water. 500 "

M. This can be applied either to the skin or to linen.

Ointments for Ulcers of the Leg.—O. Schulze (*Münchener medicinische Wochenschrift*, 1901, No. 12; *Wiener medicinische Blätter*, April 11th) gives the following formulæ:

- 1. R Triturated camphor. 2 parts;
- Zinc oxide. 15 to 20 "
- Lard. enough to make 100 "

M.

- 2. R Triturated camphor. 2 parts;
- Dissolve in
- Olive oil. 50 "
- Add
- Zinc oxide. 40 to 50 "

M. The dressing should be renewed twice or three times a day.

A Snuff for Coughs.—The *Agenda-médical* for 1901 attributes the following formula to Guéneau de Mussy:

- R Powdered gum arabic. 11 parts;
- Powdered belladonna root. 1 part;
- Morphine hydrochloride. 0.1 "

M. To be used from eight to ten times a day.

The Treatment of Eczema of the Nails.—Dr. Dubreuilh and Dr. Frêche (*Journal de médecine de Bordeaux*, April 14th) recommend in the acute stage emollient applications of marshmallow water, slightly borated, or poultices of potato pulp. With much vesiculation and oozing, powders, preferably talc or oxide of zinc, may be used. But the powder must be alternated with brief washings to obviate crusts.

When the inflammatory phenomena have been subdued, an ointment of zinc oxide, five per cent., with salicylic acid, twenty per cent., may be used. In chronic exudative forms, compresses of two-per-cent. resorcin, or painting with one-in-thirty silver nitrate solution, are of service.

To Aid Post-partum Flow.—Dr. Harriet E. Garrison (*American Medicine*, April 27th) recommends the following for the purpose of keeping the os patulous if there are signs of obstruction or insufficient flow of clear blood:

- R Fluid extract of cimicifuga racemosa, } of each, 2
- Tincture of gelsemium, } drachms.
- M.

Sig. Two drops every hour until the flow is normal.

Treatment of Pertussis by Oil of Gomenol.—Leroux and Pasteau (*Bulletin médical*, June 13, 1900; *American Journal of the Medical Sciences*, April, 1901) speak favorably of the use of an oily solution of gomenol, which is an essence obtained by distillation from a variety of *Metaleuca viridiflora*, grown in New Caledonia. From five to ten cubic centimetres of a five-per-cent. oil were injected into the gluteal muscles. The results of treatment in forty cases were generally favorable, the frequency and severity of the paroxysms being shortened and the duration of the disease reduced on an average to twelve to fifteen days. Treatment should be continued for four or five days after the last seizure.

The Treatment of Mosquito Bites.—M. Manquat (*Bulletin général de thérapeutique*, November 15, 1900; *Archives de médecine et de pharmacie militaires*, April, 1901) thinks tincture of iodine and formaldehyde the most serviceable medicaments, while menthol is deserving of consideration. He says that tincture of iodine applied freely to the recent bite of a mosquito (from some minutes to about two hours) causes the effects to disappear in from ten to twenty minutes.

For the face, upon tender skin surfaces, and in very young children, he recommends the following application:

- R Formaldehyde, 40 per cent. 5 parts;
- Alcohol, } of each. 10 "
- Water, }

M.

It should be applied for only a short period of contact and in repeated light layers, without reaching the smarting point, so as to assure a rapid evaporation of the active principle, and avoid any caustic action.

Four- or five-per-cent. menthol in eau de cologne is useful for light bites.

Sodium Bicarbonate in the Vomiting of Pregnancy.

—Monin (*Lyon médical*, January 27th; *British Medical Journal*, April 20th) has been struck by the resemblance which the symptoms presented by certain pregnant women bear to those of hypersecretion. Gastric pain, heartburn, acidity, nausea, and vomiting, occurring especially in the morning and relieved by taking food, are all symptoms commonly observed both in hypersecretion and during pregnancy. As a consequence of the suggestiveness of this observation, satisfactory results have been obtained in the case of pregnant women by administering daily five doses of sodium bicarbonate, each consisting of thirty grains given in a capsule.

NEW YORK, SATURDAY, MAY 11, 1901.

THE PROPOSED PSYCHOPATHIC HOSPITALS.

WHAT we all know perfectly well, while failing to realize its full meaning, may sometimes be put so trenchantly as to crystallize our information into realization much in the same way as a horse ridden over a frozen road skirting a body of water just ready to freeze may lead to the sudden formation of ice on the surface of the water. An instance, we think, is afforded by the following note appended by Miss Louisa Lee Schuyler, one of the vice-presidents of the State Charities Aid Association and the chairman of its committee on the insane, to her recent report to the New York State Commission in Lunacy: "There is no place in New York city (borough of Manhattan)," says Miss Schuyler, "where a person suffering from mental disorder can be received for early or preventive treatment; and there is no place in New York city (Manhattan), since the removal of the Bloomingdale Asylum to White Plains, to which a person seized with sudden and violent mania can be taken, except to the wards for the insane at Bellevue."

In the body of her report Miss Schuyler says that at last relief from the overcrowding of the insane in the State of New York is "in sight," and the time has come when effort should be directed to the prevention and cure of insanity. She accordingly advocates most eloquently the establishment of reception hospitals, or psychopathic hospitals, each to be a branch of one of the large State hospitals. As regards the psychopathic hospital for the city of New York, which would be a branch of the new Manhattan State Hospital in Central Islip, now approaching completion, in it all persons supposed to be insane and all recently committed as insane would be gathered for examination and classification with a view to their suitable distribution. Persons found not to be insane would be transferred to some general hospital,

those suffering with paresis or any other decided form of incurable insanity would be sent directly to Ward's Island or to Central Islip, and those as to whose curability there might be doubt would be kept in the reception hospital for a limited period "under the daily care and constant advice of the most eminent members of the profession." Clinical teaching would be provided for, and there would be an out-door department for the examination and treatment of persons not actually in need of constant oversight.

Miss Schuyler's report is dated November 1, 1900. Not long after that date certain occurrences in the lunatics' quarters in Bellevue Hospital made an impression on the public that can be counted on, we should think, to favor the early consummation of her plans. In our issue for January 12th we advocated for the borough of Manhattan the establishment of just such a hospital as those which Miss Schuyler has in mind. Such hospitals have been advocated by Dr. Frederick Peterson and by a number of other prominent alienists, and they are ready, as we learn from the report, to give their services. The time seems ripe, therefore, for New York's redemption from its present poverty of resources for the proper care of the acutely insane and for effective educational work in psychiatry.

PSEUDO-PHYSIOLOGY IN THE PUBLIC SCHOOLS.

WE have commented editorially more than once upon the garbled and inaccurate stuff that, under the guise of physiology, it is sought through the medium of many authorized public school text-books to inculcate in children on the question of alcohol. We are glad to learn that others, even among those who have been promoters of the legislation under which this is sanctioned, are protesting against this vicious abuse of the educational system for the purpose of inculcating the fads of cranks. We are as much alive as they are to the evils of intemperance and in thorough sympathy with all reasonable and legitimate measures for its uprooting, but we do not think that such measures entail the abolition of the proper use of alcoholic stimulants, and especially the reasonable use of light wines with meals; and we are quite sure that, however good any cause may be, it is never permanently aided by organized dishonesty. In our recent editorial in the *New York Times*, the writer says

"It is a gratifying indication of returning sanity among the friends of temperance that there is a growing protest among them against further teaching in th

schools of alleged facts about alcohol and its effects upon the human system which are demonstrably false and misleading. This is also finding intelligent expression in the educational journals, and many professional teachers of sound judgment and wide experience are taking the ground that text-books which masquerade as physiologies, but are written mainly with a view to attributing to alcohol qualities and effects which are at variance with truth and reason, do more harm than good to the temperance cause. . . . The immediate storm centre of this controversy is Connecticut. The books prescribed by the law of that State for use in schools . . . have called out a forcible protest from so conservative and conscientious an educator as Professor W. N. Rice, of Wesleyan University. Among other things taught the pupils of Connecticut public schools, he finds two statements side by side which are somewhat difficult to reconcile. One is that about one half the commitments to insane asylums are due to overindulgence on the part of the persons so committed in alcoholic stimulation. The other is that more persons become insane through the use of tobacco than because of alcohol. The intelligent pupil will reason that if about one half the insane become so from drinking, and more than one half by smoking, there cannot very well be any other causes at work, and if he speculates where to place the very large proportion of cases due to paresis, religious excitation, melancholia, accident, etc., he cannot very well resist the conclusion that he has been imposed upon by text-book writers who are either ignoramuses or cranks, or perhaps both."

In our opinion, there is more rubbish talked and written in a day on the so-called inherent evils of alcohol and tobacco, as distinguished from those consequent upon the intemperate use thereof, than upon any other subject in a month. But at any rate, whatever is published for adults, who are supposed to take what they are told merely as submitted for the approval of their own reason, it is clear that in teaching children, who are expected to accept what is taught as of authority, a sharp line should be drawn between demonstrable facts and conclusions drawn therefrom by partisans of particular theories, whether adequately or inadequately substantiated, so far as the limitations of imperfect knowledge allow.

THE SALE OF A PRACTICE.

COMPARED with what obtains in some European countries, the sale of a medical practice is rare in the United States. Still, it is sometimes effected, perhaps oftener now than a few years ago. The thing sold is somewhat vague and intangible—what the chemists might term unstable—easily disintegrated and prone to

"vanish into thin air." The transaction has always seemed to us like "buying a pig in a poke," but we are not quite ready to call it "deplorable" and "immoral," as Dr. H. Huchard, of Paris, recently did in a *consultation-clinique* at the Necker Hospital (*Journal des praticiens*, February 9th). A physician cannot sell his *clientèle*, he goes on to say, for a patient is not his property, even if he has remained faithful to him for many years, but is always free to entrust the care of his health to whomsoever he chooses. A physician may sell to a successor his library, his horse, and his carriage, says M. Huchard—and, we may add, his house, his furniture, his stable, and his instruments—but he cannot sell him his patients. One may, therefore, readily ruin himself, or at least sink a considerable sum of money to no purpose, in buying a practice.

M. Huchard seems to realize, however, that the uncertainty of transactions of this sort is not likely to prevent their occurrence, and he makes the very sensible, if not entirely original, suggestion that the purchaser of a practice agree to pay to the physician he buys out a certain percentage of the receipts from the practice for a short term of years—as he puts it, twenty-five per cent. for five years. Perhaps an improvement would be for the purchaser to undertake to pay over an annually decreasing percentage for a greater number of years, for his first year's receipts would no doubt be almost wholly the result of the exchange, but those of each succeeding year as time went on would be more and more the reward of his own professional attainments and personal qualities. It seems to us quite equitable, moreover, that, if at any time the purchaser should tire of his bargain, he should be at full liberty to relinquish the field, with the understanding, of course, that these provisions applied only to the estimated value of the practice itself, the sale of actual property being absolute.

THE FAILURE OF THE ANTIVIVISECTIONISTS IN MASSACHUSETTS.

IT is a source of great satisfaction to find a legislative committee with sufficient sense and courage to decline to report favorably on a bill designed to impose upon the community the will of sentimental agitators, especially when the particular fad concerned is that of the antivivisectionists, which has already seriously hampered medical research in Great Britain and is constantly threatening to work the same detriment in various parts of our own country. It is to be hoped that the recent action of a Massachusetts committee in so declining will have a good effect with other legislative bodies.

OUR SUBSCRIBERS' DISCUSSIONS.

LEST some of our readers may have overlooked the Special Notice to Our Subscribers, printed on page 774 of the *Journal* for May 4th, and the editorial entitled Our Subscribers' Discussions, published in the same issue, on page 772, we again call attention to the announcement. The question for the first discussion is *What is the Best Way of Treating the Stump of the Umbilical Cord?* Whoever among our subscribers, barring our own editorial staff and all persons known to be engaged in medical journalism, sends us the most satisfactory answer to this question will receive a prize of \$25. The answers must reach us on or before June 10th, and the award will be announced as soon after that date as practicable. Subscribers who are inclined to compete should read carefully both the articles in the May 4th number to which we have referred. We may now add that, since the Army Medical Department, the Navy Medical Department, and the Marine-Hospital Service furnish the *Journal* to the officers of their corps, all medical officers serving in any of those departments, whether commissioned or under contract, are entitled to enter the competition. As many of these officers and some of our other subscribers are living out of the United States, the time to elapse between now and the 10th of June seems too short to admit of their joining in the first competition. We will now announce the second question. It is this: *What is the Best Way of Prescribing Calomel as a Purgative?* We may suggest that the chief points for consideration might be: The large single dose *versus* the small and repeated dose, the size of the various doses, the time of administration (with regard to meals, the sleeping hours, etc.), the frequency of repetition of small doses, the advantages (and the reasons for them) of combining with the calomel some other drug, such as sodium bicarbonate, and the question of giving a saline aperient after the calomel. Answers to this second prize question must reach us on or before July 10th.

Ἄριστον μὲν ὕδωρ.

A STORY is told of two itinerant pill-vendors who engaged in a cut-price warfare. When the patience of one was exhausted, he approached his competitor and asked: "How is it that you can afford to undersell me? I make my pills from bread and only have to coat them." To which the other replied: "I find my pills ready made. There is a rabbit warren at the back of my house." The quack who was recently fined in a New York court for practising without a license, declared that he just put up Croton water in various kinds and sizes of bottles, coloring it with the coloring matter used in making candy, and called each bottle of mixture by a different name. This simple therapeutics must have paid well, since he says that he found it "far better than Christian Science." "Croton water," he said, "is just as good to cure rheumatism, diphtheria, cholera, or any other kind

of disease, as anything." No doubt he had the average number of recoveries among his patients. But it must have been rather humiliating for those folks who had been grumbling over their water rate to find that they had been paying high prices for small bottlefuls of the commodity.

THE PARASITOLOGY OF CANCER.

SOME noteworthy work in this field of research has been done during the last two or three years in the New York State Pathological Laboratory of the University of Buffalo by Dr. Harvey R. Gaylord, the director of the laboratory. A partial report was presented to the Medical Society for the State of New York at its annual meeting in 1899, and Dr. Gaylord publishes the first part of a further report in the May number of the *American Journal of the Medical Sciences*. Having adopted Plimmer's method of staining, he has found that investigator's micro-organism, thought to be a protozoon, present in all examples of carcinoma occurring in man.

NEW YORK UNIVERSITY'S MEDICAL PERIODICAL.

THE *New York University Bulletin of the Medical Sciences* is the title of a new quarterly publication devoted to the record of the work done in the Carnegie Laboratory and other departments of the University and Bellevue Hospital Medical College. The first number, for January, contains fifty-six pages of reading matter. Among the articles we note one of considerable interest from the historical point of view, entitled *The Development of the Conception of Disease*, by Dr. Horst Oertel, instructor in pathological histology and clinical microscopy.

THE PLAGUE AND CATTLE SHIPS FROM CAPETOWN.

THE *Boston Pilot* for April 27th expresses great dread of the introduction of the Oriental plague at some of our ports by the "dirty cattle ships" which, it says, ply freely to and from Capetown, and it gives the government scant credit for its efforts to guard against the "black death." We feel confident, however, that the Marine-Hospital Service is keeping a close watch of all possible sources of infection, and may be counted on to display its customary energy in case of need.

THE REST-TREATMENT IN TUBERCULOUS PULMONARY DISEASE.

NEARLY absolute rest is regarded by many physicians who have met with the greatest success as quite essential in the treatment of the active stage of early tuberculous disease of the lungs. Bernheim (*Zeitschrift für Tuberkulose*, i, 6; *Centralblatt für innere Medizin*, April 20th) says of it that it diminishes the self-intoxication, regulates the temperature, and prevents hæmorrhages and the extension of the bacilli. It should be kept up, he adds, until the evening temperature remains permanently normal.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 13th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, May 14th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, May 15th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, May 16th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Atlanta Society of Medicine.

FRIDAY, May 17th: New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending May 4, 1901:

DISEASES.	Week end'g Apr. 27		Week end'g May 4	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	20	7	22	11
Scarlet Fever.....	669	44	642	38
Cerebro-spinal meningitis.	0	6	0	5
Measles.....	330	9	319	9
Diphtheria and croup.....	290	58	288	45
Small-pox.....	56	8	86	10
Tuberculosis.....	287	204	283	147

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending May 4, 1901:

- LAW, H. L., Surgeon, retired. Detached from the recruiting rendezvous, Buffalo, and ordered home.
- RODMAN, S. S., Assistant Surgeon. Detached from the *Adams* and ordered to the *Alert*.
- WRIGHT, B. L., Assistant Surgeon. Ordered to the *Massachusetts*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from April 27 to May 4, 1901:

- CURLING, JOHN, Captain and Assistant Surgeon, will report at San Francisco for transportation to Manila.
- DE WITT, CALVIN, Lieutenant-Colonel and Deputy Surgeon-General, is detailed as a member of the examining board at the Army Medical Museum Building, Washington, vice ALFRED A. WOODHULL, Colonel and Assistant Surgeon-General, retired, relieved.
- KILBOURNE, HENRY S., Major and Surgeon, is detailed as a member of the examining board at the Presidio of San Francisco, vice BENJAMIN F. POPE, Lieutenant-Colonel and Deputy Surgeon-General, relieved.
- MASON, CHARLES F., Captain and Assistant Surgeon, will report in person to CALVIN DE WITT, Lieutenant-Colonel, for examination as to his fitness for promotion.
- METZGER, JOHN A., Major and Surgeon, will report in person to the commanding general, Department of California, for transportation to Manila.
- RAYNOR, WILLIS J., Captain and Assistant Surgeon, United States Volunteers, is relieved from duty at Fort Wash-

kie, Wyoming, to take effect upon the expiration of the leave granted him, when he will proceed to San Francisco for transportation to Manila.
WILLIAMS, ROBERT E., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague, were reported to the surgeon-general during the week ending May 3, 1901:

Small-pox—United States and Insular.

San Francisco, California.....	Apr. 13-20.....	2 cases.	
Chicago, Illinois.....	Apr. 20-27.....	9 cases.	1 death.
Freeport, Illinois.....	Apr. 20-27.....	1 case.	
Evansville, Indiana.....	Apr. 20-27.....	1 case.	
Wichita, Kansas.....	Apr. 13-20.....	30 cases.	
Lexington, Kentucky.....	Apr. 20-27.....	2 cases.	
Fitchburg, Massachusetts.....	Apr. 13-20.....	2 cases.	
Holyoke, Massachusetts.....	Apr. 20-27.....	1 case.	
Bay City, Michigan.....	Apr. 13-20.....	5 cases.	
Detroit, Michigan.....	Apr. 20-27.....	1 case.	
At 94 places in Michigan.....	Present.....	8 cases.	
Minneapolis, Minnesota.....	Apr. 16-22.....	8 cases.	
Omaha, Nebraska.....	Apr. 13-20.....	11 cases.	
Manchester, New Hampshire.....	Apr. 20-27.....	5 cases.	
New York, New York.....	Apr. 13-27.....	94 cases.	18 deaths.
Cincinnati, Ohio.....	Apr. 19-26.....	4 cases.	
Allegheny City, Pennsylvania.....	Apr. 12-19.....	3 cases.	
Johnstown, Pennsylvania.....	Apr. 13-20.....	1 case.	
Philadelphia, Pennsylvania.....	Apr. 13-27.....	12 cases.	2 deaths.
Steelton, Pennsylvania.....	Apr. 20-27.....	1 case.	
Williamsport, Pennsylvania.....	Apr. 20-27.....	3 cases.	
Ducktown, Tennessee.....	Apr. 20-present		
Memphis, Tennessee.....	Apr. 13-20.....	24 cases.	
Nashville, Tennessee.....	Apr. 20-27.....	14 cases.	
Salt Lake City, Utah.....	Apr. 13-20.....	17 cases.	
Cebu, Philippines.....	Mar. 12.....	5 cases.	1 death.
Manila, Philippines.....	Mar. 8-16.....	8 cases.	
Agua Buenas, Porto Rico.....	To Apr. 10.....	4 cases.	
Ciales, Porto Rico.....	To Apr. 10.....	1 case.	
Isabela, Porto Rico.....	To Apr. 10.....	4 cases.	
Manati, Porto Rico.....	To Apr. 10.....	1 case.	
Ponce, Porto Rico.....	To Apr. 10.....	34 cases.	
San Juan, Porto Rico.....	To Apr. 10.....	6 cases.	

Small-pox—Foreign.

Hong Kong, China.....	Mar. 8-23.....	23 cases.	10 deaths.
Panama, Colombia.....	Apr. 15-22.....	5 cases.	3 deaths.
Guayaquil, Ecuador.....	Mar. 2-23.....		3 deaths.
Cairo, Egypt.....	Mar. 25-Apr. 1.		2 deaths.
Paris, France.....	Apr. 6-13.....		7 deaths.
Liverpool, England, Great Britain.....	Apr. 6-13.....		2 deaths.
Cardiff, Wales, Great Britain.....	Mar. 8-30.....	6 cases.	1 death.
Dundee, Scotland, Great Britain.....	Apr. 6-13.....	2 cases.	
Glasgow, Scotland, Great Britain.....	Apr. 12-19.....		6 deaths.
Mexico, Mexico.....	Apr. 7-14.....		1 death.
St. Petersburg, Russia.....	Mar. 30-Apr. 6.	14 cases.	3 deaths.
Warsaw, Russia.....	Mar. 23-30.....		5 deaths.
Singapore, Straits Settlements.....	Mar. 2-16.....		1 death.

Yellow Fever.

Vera Cruz, Mexico.....	Apr. 8-16.....	1 death.
------------------------	----------------	----------

Plague—Foreign and Insular.

Adelaide, Australia.....	Feb. 28.....	1 case.
Canton, China.....	Feb. 28.....	Epidemic.
Chan Tsin, China.....	Feb. 28.....	Epidemic.
Fatshan, China.....	Feb. 28.....	Epidemic.
Hong Kong, China.....	Mar. 8-23.....	22 cases. 21 deaths.
Singapore, Straits Settlements.....	Mar. 7-16.....	2 deaths.
Honolulu, Hawaii.....	Mar. 29.....	1 death.
Manila, Philippines.....	Mar. 8-16.....	10 cases. 8 deaths.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine Hospital Service for the Seven Days ending May 2, 1901:

- CARMICHAEL, D. A., Surgeon. To assume temporary command of the San Francisco Quarantine Station.
- GREENE, J. B., Passed Assistant Surgeon. Detailed for temporary duty in the Bureau.
- HEISER, V. G., Assistant Surgeon. To proceed to Norfolk, Virginia, for special temporary duty, April 27, 1901. To proceed to Quebec, Canada, and report to the United States Commissioner of Immigration for duty, May 1, 1901.

SCHLAAR, W. F., Hospital Steward. Granted leave of absence for 26 days, March 29, 1901.

WERTENBAKER, C. P., Passed Assistant Surgeon. To proceed to Prescott, Arkansas, for special temporary duty.

The East Side Physicians' Club.—One hundred and seventy-five doctors on the east side, below Fourteenth Street, New York city, have organized the East Side Physicians' Club, with a clubhouse at No. 165 Henry Street, and intend to establish a medical library.

Rumor that the Sultan of Turkey has Killed his Physician.—The Constantinople correspondent of the *Daily Express* (London) says: "It is rumored that the Sultan shot dead a physician who, while attending him for ear complaint and massaging him, unwittingly caused his Majesty intense pain.

Changes of Address.—Dr. Edward Bennet Bronson, to No. 10 West Forty-ninth Street, New York; Dr. Joseph D. Bryant, to No. 32 West Forty-eighth Street, New York; Dr. John F. Erdmann, to No. 60 West Fifty-second Street, New York; Dr. A. Goldhammer, to No. 240 East Seventy-second Street, New York; Dr. Augustus A. Hussey, to No. 409 Stuyvesant Avenue, Brooklyn; Dr. Ogden C. Ludlow, to No. 234 West One Hundred and Thirty-fifth Street, New York.

The Edward N. Gibbs Memorial Prize Fund.—The trustees of the New York Academy of Medicine have the pleasure of announcing the receipt of ten thousand dollars from Mrs. Sarah Barker Gibbs and Miss George Barker Gibbs for the establishment of the Edward N. Gibbs Memorial Prize Fund, the income to be awarded triennially to the physician of regular standing in the medical profession of the United States of America who shall present the best original essay upon the ætiology, pathology, and treatment of the diseases of the kidney.

Banquet to a Richmond (Va.) Physician.—A banquet was tendered to Dr. J. B. McCaw by the Academy of Medicine and Surgery at Richmond, Va., on April 25th, to mark the retirement of Dr. McCaw from the practice of medicine in that city, after an honored and efficient service lasting for fifty-seven years. Dr. McCaw graduated from the University of New York in 1844. During the evening Dr. McCaw was presented with a handsome loving cup. Dr. George Ross acted as toastmaster and Dr. Johnston, Dr. Brock, and Dr. Hugh M. Taylor made addresses.

The Medical Department of the Brooklyn Navy Yard is established in new quarters. The building is two stories high and about forty feet square. The upper floor is being fitted out for a residence for the pharmacist. The lower floor is fitted out with all the implements of surgery and necessaries for the pursuit of the medical profession which there are in the best hospitals in the country. In no other navy yard or naval station in the country is there anything approaching it in newness and excellence of design. Nearly every modern appliance is at hand, and the operating room is also finely equipped.

The Quarantine Station at New York.—The Assembly at Albany, on April 23d, adopted a resolution providing for a special committee of three to investigate the quarantine station at New York and suggest appropriate legislation to the legislature of 1902. One purpose of

the committee's work is to learn how the station may be made self-supporting. The appropriation for its expenses was fixed at \$1,000. For many years the station has been self-supporting, according to Dr. Doty, Health Officer of the Port, but the introduction of modern apparatus and the establishment of a laboratory have increased the cost of the station, until now it is necessary to ask for an appropriation from the State of from \$8,000 to \$10,000 a year. The Quarantine Commission, which is separate from the Health Officer's Department, was entirely supported by the State. The investigation will probably include both branches.

Commencement Exercises.—The fourteenth annual commencement of the Gross Medical College was held at Denver, Col., on April 25th. There were fifteen graduates, two of whom were women.—The Baltimore Medical College held its twentieth commencement exercises at Baltimore on April 23d. There were nearly one hundred successful candidates.—The annual commencement exercises of the Omaha Medical College were held at Omaha, Neb., on April 25th. There were twenty-three graduates.—Commencement exercises of the University College of Medicine were held at Richmond, Va., on May 2d. There were eighty-five graduates in the medical class.—The Cooper Medical College commencement exercises were held at San Francisco, Cal., on April 23d. There were 27 graduates.—The Albany Medical College, Albany, N. Y., held its regular commencement exercises on May 1st, diplomas being awarded to twenty-eight students.

The Philadelphia Health Bureau Furnishes an Exhibit for the Pan-American Exposition.—In response to the invitation to furnish an exhibit for the Pan-American Exposition, a large portfolio of literature and photographs pertaining to the work of the Bureau of Health has been completed under the direction of Dr. Welsh, of the Municipal Hospital, Philadelphia. The portfolio contains complete collections of blanks and circulars of instruction issued by the bureau for use in its several divisions, together with extracts from reports showing the sanitary work performed, statistical health diagrams and photographs illustrating the city's facilities for handling infectious diseases. The pictures include interior views of the bacteriology laboratories, a bird's-eye view of the Municipal Hospital and separate pictures of the small-pox and leper buildings, the temporary and emergency buildings, interior views of diphtheria wards, the new deadhouse, the disinfecting plant, and other views of the hospital buildings and grounds.

Scarlet Fever.—Scarlet fever has reached an epidemic form in Pittsburgh and vicinity.—It has also made its appearance at Norwich, N. Y.

Reappearance of Yellow Fever in Cuba.—Yellow fever has appeared in Havana, and the order of the secretary of the treasury suspending the quarantine regulations has been revoked.

"Pink-eye."—An epidemic of "pink-eye" is reported among New York city's school children. It is popularly believed to have some connection with the progress of the excavation of city streets in the spring.

Typhoid.—The epidemic at New Haven is, from all accounts, losing its virulent features. Only a few new cases and but one death were reported during the past

May 11, 1901.]

week. The belief is spreading that the diagnosis in many cases may have been wrong.

Diphtheria.—Three children in the family of Christian Scientists at Fanwood, N. J., were taken ill with diphtheria recently. One died on April 18th and then physicians were called in. Despite their efforts, another child died on April 23d. The third may yet be saved. Several other cases were also reported in the neighborhood.—The disease has made its appearance in Bergen, N. Y.; Scotch Plains, N. J., and at Highbridge, in Bronx Borough, New York. Forty cases were reported at the latter place, and the board of health has ordered the closing of the public school there. The cases are of a mild nature.

Small-pox.—The prevalence of small-pox continues. In New York several cases have been discovered in the New York Foundling Asylum and in the Italian colony in Brooklyn. Altogether, so far as the city is concerned, the present epidemic will stand well forward in the list of those which have occurred since the health department began keeping a record in 1868. Nearby places that have been visited are Newark, N. J., where it made its appearance in the Essex County Hospital for the Insane, at Jersey City, College Point, and Southington, Conn. At the latter place is domiciled the wife of a minister, who refuses to see physicians, believing in the healing power of prayer. The patient left New York on April 17th on the New York, New Haven and Hartford Railroad, and other residents of the Connecticut town are extremely indignant. The woman's house in this city was fumigated, and fumigation and vaccination have been lively in Southington. The crisis in the case has not been reached.—Other places where small-pox has made its appearance are in the province of Ontario, Canada; several points in Illinois; at Cleveland, Ohio; Philadelphia, and elsewhere in Pennsylvania.—Suits for damages against New York, through the board of health, are threatened on the part of two residents of Brooklyn Borough, who, it is said, were removed to the hospital for contagious diseases on North Brother Island within the past month, one as a small-pox patient and the other as a suspect. Both, it is stated, were detained under surroundings in which they were likely to become contaminated. The doctors assert that the rash that the men had was suspicious. One had contracted scurvy at Cape Nome, Alaska.—According to tables compiled by the United States Marine-Hospital Service, at Washington, there were 16,734 cases of small-pox in the United States between December 28, 1900, and April 19, 1901, of which 225 proved fatal. For the same period a year ago there were only 8,013 cases, but the deaths numbered 439.—The disease has obtained a foothold in the Lathrop Memorial Home, at Albany, in which there are thirty-five children, and it has been quarantined.—From Bradford, Pa., comes the story of the destruction of a pest house by fire after a mob had prevented the authorities from admitting small-pox patients.—Other points visited were Wheeling, W. Va., Chicago, several points in Minnesota, Michigan and Wisconsin, Cleveland, Ohio; Kansas City, Mo.; Fitchburg, Mass.; Salt Lake City, and Grafton, W. Va. In the latter town a school teacher, afflicted with the disease, kissed every one of her sixty-five pupils, and now the board of education has prohibited kissing in the schools.

A McKees Rocks Medical Society.—Physicians resident at McKees Rocks and district, Pa., recently organ-

ized the McKees Rocks Medical Society. The following are its officers: President, Dr. J. A. Barr; vice-president, Dr. P. T. Sullivan; secretary, Dr. Walter Deane, and treasurer, Dr. J. W. Omstott.

The Clinical Society of Maryland met, on April 19th, at Baltimore. The following papers were read: Distribution of Cases of Consumption in Baltimore, by Dr. C. Hampson Jones; Registration of Tuberculosis, by Dr. Lawrence F. Flick, of Philadelphia; and The Care of the Tuberculosis Patient, by Dr. H. Warren Buckler. The subject considered by the society was The State and Municipal Care of Pulmonary Tuberculosis.

The Burlington County (Pa.) Medical Society.—At the annual meeting of the Burlington County (Pa.) Medical Society, on April 16th, the following delegates were elected to the State Medical Society: Dr. Parson, Dr. Dubell, Dr. Flynn, Dr. Stroud, and Dr. I. W. Hollingshead. These delegates were elected to attend the American Medical Association: Dr. Parry, Dr. E. Hollingshead, and Dr. J. D. Janney.

The Medical Association of the Greater City of New York will hold a stated meeting at the New York Academy of Medicine, 17 West Forty-third Street, on Monday, May 13th. The order of exercises includes the reading of the following papers: I. Gliosarcoma of the Base of the Brain. Pressing upon and in Front of the Left Lobe of the Cerebellum, with Remarks on the Localization of Cerebellar Disease, by Dr. Henry W. Berg. II. Remarks on the Surgical Aspects of the Case, by Dr. Howard Lilienthal. III. Discussion by Dr. B. Sachs, Dr. L. Putzel, Dr. Pearce, Dr. Bailey, Dr. George E. Brewer, Dr. Samuel Lloyd, and others.

A Hospital Celebrates its 150th Anniversary.—The Pennsylvania Hospital of Philadelphia will celebrate the 150th anniversary of its founding to-day, May 11th. The institution was the first hospital established in the American colonies.

Hospital Staff Changes.—Miss Agnes D. Randolph, superintendent of the Virginia Hospital, of Richmond, Va., has tendered her resignation.—The entire staff of resident physicians at the Hahnemann Hospital, Philadelphia, with the exception of Dr. Usilton, resigned on April 17th. The staff consisted of Dr. E. N. Huff, Dr. J. G. Blackwell, Dr. F. A. Whiteman, Dr. A. P. Hallowell, and Dr. Usilton. At a meeting of the Board of Trustees on Tuesday it was decided to request the resignation of Dr. Huff, Dr. Blackwell, and Dr. Whiteman, to take effect on May 16th. Upon being served with the notice from the board the three physicians named promptly resigned, and Dr. Hallowell resigned through sympathy with the others. The physicians declare that all the trouble is the result of petty complaints made by Miss Brownlee, directress of nurses.—Miss Sophia F. Palmer, superintendent of the City Hospital of Rochester, N. Y., has tendered her resignation.—Dr. Ralph W. Seiss, for seventeen years professor of diseases of the ear at the Polyclinic Hospital, Philadelphia, has resigned, and Dr. Francis R. Packard, who has resigned the post of dean, has been elected to fill his place. Dr. B. M. Randolph, of Richmond, Va., has been elected dean, in succession to Dr. Packard, and director of the laboratories, succeeding the late Dr. Thomas S. Kirkbride, Jr.—Dr. Samuel D. Risley has resigned his post as senior professor of diseases of the eye at the Phil-

adelphia Polyclinic and College for Graduates in Medicine. As a mark of appreciation of his long service the board of trustees has created an emeritus chair and has elected Dr. Risley to fill it. Dr. William Campbell Posey has been elected to the chair made vacant by Dr. Risley's resignation. Dr. Posey is a graduate of the college and medical department of the University of Pennsylvania.—Dr. Thomas H. Magness, of Baltimore, has been appointed resident physician at the Baltimore University Hospital, to succeed Dr. W. D. Bacon, and Dr. Joseph T. Devine, of New York, was appointed assistant resident physician, to succeed Dr. Edward C. Moriarity.—Alexander Miqucu has been elected superintendent of the French Hospital at San Francisco. Other officers elected are: August Bergez, collector for the society; Dr. Dudley Tait, re-elected surgeon of the hospital; Dr. T. P. Canac-Marquis, gynecologist; Dr. M. W. Frederick, ophthalmic surgeon; Dr. Louis E. Brun, dentist; Dr. E. R. Berges, resident physician. Dr. M. Krotoszyner and Dr. C. F. Pawlicki have been re-elected.—Dr. A. S. Priddy has been elected first assistant superintendent of the Southwestern Hospital of Virginia, located at Marion. Dr. Priddy is a member of the legislature from Charlotte county and is one of the leading physicians of Virginia.

Hospital Buildings and Endowments.—A charter has been obtained for the Presbyterian Hospital of Atlanta, Ga.—The Board of Public Service of Cincinnati, Ohio, has agreed to allow the Cincinnati Hospital an additional \$7,500 on condition that the branch hospital is kept open.—Anson R. Flower, of New York, has presented \$24,000 to Flower Hospital for the purchase of adjoining property, to be fitted up for a dispensary and nurses' dormitory. An endowment of \$10,000 has also been received from Mrs. H. R. Kunhardt.—Proposed additions to the Rochester (N. Y.) State Hospital will double its capacity. The estimated cost is \$350,000.—The treasurer's report of the New York Hospital Saturday and Sunday collection shows that the collections for 1900 amounted to \$75,000, an increase of \$5,000 over 1899.—The French Benevolent Society has acquired title to the property No. 450 to 456 West Thirty-fourth Street, New York, for a consideration of \$43,300. The society will build a hospital on the site.—Ground has been broken for an annex to St. Vincent's Charity Hospital, Cleveland, Ohio, to cost about \$40,000, and to be used exclusively for women patients.—The will of the late George L. Thorndike, of East Boston, Mass, directs that his estate, so soon as it exceeds in value \$200,000, shall be used to construct a hospital in some suitable location in that city, to be furnished free by the city.—The Emergency Hospital of the Pan-American Exposition at Buffalo is reported ready for patients. The staff consists of two physicians and two nurses. Beginning this month, it will be increased as circumstances demand. Thus far, only two men have been killed and a dozen permanently injured at the exposition. The average number of casualties is eight per day.—It is planned to erect a new building for the California Eye and Ear Hospital, in San Francisco, at a cost of \$20,000.—The Eclectic Medical Institute at Cincinnati will shortly renovate and equip the old Sexton homestead as a hospital.—Governor Odell has signed the bill appropriating \$53,000 for the further construction of the Dannemora Hospital for Insane Convicts at Dannemora, N. Y.—The Franciscan Sisters of the Third Order of St. Francis, whose mother house is lo-

cated at Lafayette, Ind., have acquired ground at Louisville, Ky., upon which they will erect a large hospital. The building will be L-shaped and four stories high and the additions will be built as the funds are raised by contributions. The same order is building the St. Edward's Hospital in New Albany, Ky.—Mayor Van Wyck has declined to approve Senator Hennessy's bill enabling New York to establish a reception hospital in Bronx Borough at a cost of \$300,000.

Foreign Obituary Notes.—Dr. Giulio Bizzozero, professor of general pathology in the University of Turin, died of pneumonia on April 8th, at the age of fifty-five years. Dr. Bizzozero has published a large number of monographs, giving the results of his studies in various lines, each one of which is a model in every respect. He was an admirable and very popular teacher and a clear, forceful and most instructive writer. His latest work, which was published just prior to his death, was concerned with the etiology and prevention of cancer.—Dr. Max Ring died recently in Berlin at the age of eighty-three years. For the past forty years Dr. Ring has devoted most of his energies to purely literary work, but had throughout his life maintained a close affiliation with medicine and medical men.

Erratum.—In our list of births, marriages, and deaths, published last week, it was announced that a son had been born to Dr. and Mrs. S. Nelson Irwin, whereas we learn now that it was a daughter. The error was not ours.

Births, Marriages, and Deaths.

Married.

ARMSTRONG—FISKE.—In Mount Vernon, New York, on Tuesday, April 30th, Dr. Edward Vanderpool Armstrong, United States Navy, and Miss Gertrude Chandler Fiske.

COLSON—WEEKS.—In Savannah, Georgia, on Tuesday, April 30th, Dr. James H. Colson, of Waldo, Florida, and Miss Eloise Weeks.

DEVLIN—DAME.—In Brooklyn, on Tuesday, April 30th, Dr. James Lawrence Devlin and Miss Florence Eugenia Dame.

HENRY—SLOAN.—In New York, on Tuesday, April 30th, Dr. Nelson Herrick Henry and Mrs. Sarah Rodgers Sloan.

MCCARTHUR—KILCREASE.—In Stockton, Alabama, on Thursday, April 25th, Dr. A. McArthur, of Rembert, Alabama, and Miss Mary Kilcrease.

MUNSON—PEENE.—In Yonkers, New York, on Wednesday May 1st, Dr. Edwin Sterling Munson, of New York, and Miss Edna May Peene.

SMITH—EDMONDSTON.—In Washington, on Tuesday, April 30th, Dr. Edward Sanford Smith and Miss Blanche Eleanor Edmondston.

TROTTER—BARLING.—In Cienfuegos, Cuba, on Tuesday April 9th, Dr. Frederick Eugene Trotter, United States Marine-Hospital Service, and Miss Harriet Everett Barling.

Died.

ALMON.—In Halifax, Nova Scotia, on Friday, April 26th, Dr. Thomas Ritchie Almon.

CORNELL.—In New York, on Wednesday, May 1st, Dr. Clarence W. Cornell, in the forty-sixth year of his age.

GREENLEAF.—In Ipswich, Massachusetts, on Sunday, April 28th, Dr. Robert W. Greenleaf, of Boston, in the forty-seventh year of his age.

LYON.—In New York, on Saturday, May 4th, Dr. Samuel K. Lyon, in the forty-sixth year of his age.

RHOADS.—In Reading, Pennsylvania, on Saturday, May 4th, Dr. M. Albert Rhoads, in the fifty-third year of his age.

ROSSE.—In Washington, on Friday, May 3d, Dr. Irving C. Rosse, in the fifty-fourth year of his age.

THOREN.—In Chicago, on Monday, April 29th, Dr. John Thoren, in the thirty-sixth year of his age.

Pith of Current Literature.

Journal of the American Medical Association, May 4, 1901.

The Gyromele in the Diagnosis of Stomach and Intestinal Diseases. By Dr. Fenton B. Turck.—The gyromele, or revolving sound, is a flexible steel cable, terminating in a more flexible steel spiral end. This spiral end is provided with a metallic pellet, and covered by a sponge, lamb's wool, or cotton. The flexibility of the sound is of such a degree as to adapt it accurately to the site, shape, and size of the organ. By means of the revolving apparatus to which the sound is attached, vibrations are produced which can be palpated and auscultated externally, thus giving exact information of the presence and locations of the revolving cable. The situation of the metal sound can also be verified by means of the x-rays. The fluoroscope and the skiagraph give excellent results. Percussion of the inflated stomach is rendered more facile and exact when the border-line of the stomach has been established beyond doubt, by means of the introduced cable.

A New Operative Method to Expose the Seminal Vesicles and Prostate for Purposes of Extirpation and Drainage. A Preliminary Report. By Dr. Eugene Fuller.

Myasthenia Gravis Pseudoparalytica (Asthenic Bulbar Paralysis). By Dr. J. R. Buist and Dr. E. G. Wood.

Limitations of the Laryngologist in the General Treatment of Nose and Throat Diseases. By Dr. H. W. Loeb.—The limitations, according to the author, are these: (1) Acute conditions of the nose and throat, influenced by remedies which have an immediate local effect; (2) rheumatic nose and throat conditions which exhibit a positive and early relief under appropriate treatment; (3) syphilis of the nose and throat, where general treatment may be best observed by watching its effect upon the local lesion, and where the local process is rapidly destructive. Even under these conditions, the author believes, the patient's chances might be improved by assistance from one whose attention is less directed to localism.

Absolute Increase of Measurement from the Anterior Superior Spine to the Malleolus as a Sign of Hysteric Hip Disease. By Dr. James Jackson Putnam.—Though a search through the literature of hysteria shows that this sign has not been wholly unnoticed, it has not, so far as the author knows, been recognized as a characteristic of hip disease.

A Case of Transient Motor Aphasia, Complete Anomia, nearly Complete Agraphia and Word Blindness Occurring in a Left-handed Man, with Special Reference to the Existence of a Naming Centre. By Dr. Charles S. Potts.

The Pharmacology of the Nitro-sugars. By Dr. C. R. Marshall.

The Classical Cæsarean versus Porro Cæsarean. By Dr. George M. Boyd.—The author believes: (1) That the life of the infant alone, under certain conditions, justifies the Cæsarean section; (2) that the classical Cæsarean has as low a mortality as an easy ovariectomy; (3) that the classical Cæsarean is less mutilating than the Porro Cæsarean, and, with the patient in good condition, is therefore the operation of choice; (4) that the Porro Cæsarean has about the same mortality as has hysterectomy for fibroids, and should be performed when the pa-

tient demands it, or when infection or a neoplasm of the uterus makes it necessary; (5) that the physician should always be prepared to perform the Cæsarean section on a multipara with the history of one or more dead children.

Ocean Climates, their Effects and the Cases they Benefit. By Dr. John A. Robison.

Adhesive Rubber Dam for the Prevention of Possible Infection at the Site of Operation. By Dr. J. B. Murphy.

The Present Status of Spinal Surgery. By Dr. Samuel Lloyd.

Boston Medical and Surgical Journal, May 2, 1901.

Contusions of the Abdomen. By Dr. Charles L. Scudder.—The problem presented to the surgeon when he meets with a case of contusion of the abdomen is definite in its demands, but often difficult of solution. These questions must be answered: Is operation necessary? Are there lesions of viscera? Two classes of cases should not be operated upon at first: (1) That class in which little or no shock is present and in which there are absolutely no localizing signs; and (2), that class in which profound shock, amounting perhaps to collapse, exists. Immediate operation is demanded in persistent, moderate shock, with or without localizing signs; also, in cases of progressing hæmorrhage, and in cases of peritoneal infection. Having determined that definite lesions exist in any of the viscera, the form of treatment to be adopted is pretty generally accepted.

Observations on the Use of Antistreptococcus Serum in the Treatment of Puerperal Sepsis, with a Report of Five Cases. By Dr. Frank A. Higgins.—In general, the author believes that the serum treatment has no place in the routine treatment of puerperal sepsis, that it should only be used in desperate cases after failure to obtain improvement by other and usually more efficient methods, and that if no improvement is shown after use for two, or at most three, days and the injection of from forty to sixty cubic centimetres, it should be discontinued. He believes, moreover, that its use is not free from danger, that it usually lowers the pulse and temperature, but at the same time that it has a correspondingly depressing effect upon the patient, and that it has not apparently lowered the mortality of the disease. With regard to the general treatment of puerperal sepsis, early curettage of the uterus, carefully performed as soon as the diagnosis is established, is of the first importance. Following curettage, and sometimes in place of it in the mild cases, intra-uterine douches have proved to be of much value. For constitutional treatment: Stimulation, tonics, and forced feeding, with moderate diuresis and catharsis.

A Case of Cæsarean Section in a Face Presentation, Complicated by Uterine Fibroid. By Dr. Emma S. Call.

Notes from the Neurological Department of the Massachusetts General Hospital: Exophthalmic Goitre and Fright. By Dr. E. W. Taylor.—In each of the three reported cases the association of a definite emotional disturbance with the symptoms which came on immediately afterward is too close to be disregarded. Some unknown predisposition, as in all other diseases, must be assumed; but the exciting cause, reasonably enough, may be regarded as fright. The manner of development of this perfectly characteristic disorder from such a cause is naturally, as yet, quite beyond our power of comprehension. If clinical experience, however, bears out the ætiological relationship, it must none the less be accepted and seriously regarded, even though our knowledge as yet is

purely empirical. From every point of view, it is desirable that cases should be reported, to the end that more light may be thrown upon a problem which is of the most intimate concern, not only to the physician, but to the public at large.

Medical Record, May 4, 1901.

The Operation for Radical Cure of Inguinal Hernia, at the End of the Century, as I Saw it Performed by Bassini, Lucas-Championnière, De Garmo, Coley, and Broca. By Dr. Campbell Ford.—The author gives an interesting description of the methods of each of the operators mentioned in the title. He considers Bassini's use of silk indefensible, as few at the present time will question that kangaroo-tendon may be satisfactorily chromicized and reliably sterilized. The use of silk for ligating and tying off the omentum is far less defensible than its use for suturing; yet the author agrees with De Garmo, that if for any reason he should be compelled to give up kangaroo-tendon he would go back to silk. He believes that De Garmo's method of suturing the external oblique and the pillars of the ring by taking a wide stitch is a good one.

Varicella in Adults. By Dr. Alvah H. Doty.—The author concerns himself in the matter of the practical distinguishing of chicken-pox from small-pox. In all circumstances it should be borne in mind that this distinction is made by the appearance of the eruption: its character, the manner in which it appears, and its distribution or location. Constitutional symptoms should not be given undue prominence in diagnosis; they are important as corroborative evidence, but they should be considered after the eruption has been studied. He strongly condemns the use of the term "varioid," which is variously accepted as indicating a mild, less dangerous, or distinct type of small-pox. The use of this term, he asserts, unquestionably tends to carelessness, as in these cases there is commonly a relaxation in the usual precautions taken to prevent the extension of small-pox. Therefore, cases of "varioid" are apt to be of special danger to the public health. Although "varioid" represents a mild attack of small-pox, it is capable of producing in others the most malignant form of this disease.

A Plea for the Conservation of Breast Milk in Whole or in Part. By Dr. Thomas S. Southworth.—The author agrees with Dr. Koplík, who advocates the utilization of part breast feeding when possible. He combats the impression that so soon as a child digests several feedings daily from the bottle, it is a matter of little consequence how soon the weaning is completed. Early weaning to the bottle is fraught with very serious dangers to the child. The career of the infant whose food is, in part at least, breast milk, is much more likely to be uneventful. The direct and indirect danger of digestive disturbance and varying grades of malnutrition in those who receive the bottle alone can scarcely be set forth too strongly.

On Bandages for Nephroptosis. By Dr. George M. Edebohls.—The author divides bandages for movable kidney into two general classes: 1. Simple bandages and apparatus embodying the feature of a special kidney pad. 2. Simple bandages that act by supporting the entire contents of the abdomen, sustaining and more or less immobilizing the movable kidney or kidneys on top of the intestinal mass. 3. All the relief to be got from bandages in cases of movable kidney is obtainable from one of two devices, either from an elastic bandage, en-

circling and sustaining well the lower two thirds of the abdomen, or from a long and low-reaching corset, fitted and adjusted with the same end in view. 4. The relief obtainable from bandages in any case of movable kidney will depend upon the presence and the degree of any associated enteroptosis. The greater the degree of associated general enteroptosis, the better the prospects of relief from a bandage or corset. When movable kidney exists without general enteroptosis, no form of apparatus will prove satisfactory. 5. All forms of apparatus with special kidney pads or trusses are to be absolutely rejected because they are impotent to fix and sustain a movable kidney, and because any pressure they may exert is injurious to either the kidney or to neighboring organs, especially the vermiform appendix, or to both. 6. In all cases in which relief of symptoms cannot be obtained from either a proper simple bandage or a corset, nephropexy is indicated.

Version: Indication, Technique, Limitation. By Dr. S. Marx.

Axis-traction Forceps. By Dr. Egbert H. Grandin.—The author asserts that one needs only to understand the use of the axis-traction forceps to value them highly. With them there will be fewer impossible forceps deliveries, far less avoidable damage to the maternal parts, and fewer intracranial injuries laid to the door of one of the most useful and beneficent instruments ever devised.

Cæsarean Section. By Dr. Edwin B. Cragin.

Medical News, May 4, 1901.

Medical Department of the University of Pennsylvania. By Dr. Charles W. Dulles.

A Report of Twenty-four Operations Performed during Spinal Analgesia. By Dr. William Seaman Bainbridge.—Though twenty-four cases are given in detail, fifty cases are considered by the author in drawing his conclusions, as follows: 1. Cocaine is far more satisfactory than eucaine. The latter is less potent, more evanescent, the areas of analgesia are frequently "patchy." Cocaine produces no more unpleasant after-effects than eucaine and is decidedly more reliable. 2. Analgesia to the level of the diaphragm can be depended upon in all cases where a moderate dose of a potent solution of cocaine has been introduced by lumbar puncture. 3. Complete analgesia, including the eyes, mouth, and throat, has occurred. It does not entail more severe after-effects than when the lower extremities only are involved. 4. The preparation of the patient as for a general anæsthetic diminishes all the unpleasant effects of cocaine and eucaine and often prevents them altogether. 5. By moderate doses of bromides before the injection the initial vomiting is frequently avoided and the liability of headache lessened. 6. In neurotic patients there are often hysterical symptoms directly following the completion of the injection, but, as a rule, in a few moments a calm follows and the patient lies perfectly still. 7. Initial nausea and vomiting often occur soon after the puncture, but last only for a moment or two, and usually do not recur during the operation. 8. Analgesia lasts for from thirty minutes to four hours. 9. Depression after the puncture is inconsiderable. 10. The preparation of the patient, the use of nitroglycerin by hypodermic injection, or the employment of coal-tar products with caffeine, controls the headache which is in many instances an after-effect of spinal puncture. 11. In a few cases there may be motor paraplegia or vertigo. Both are temporary. 12. Spinal puncture has not affected normal or

diseased kidneys. 13. Usually the tactile power, muscular sense, and the ability to detect heat and cold are retained. 14. Usually the patient sleeps the first night. 15. There is often a rise of temperature of a few degrees within eight or ten hours of the operation. Whether this is the direct result of the puncture or the effect of psychic disturbances is not determined. The circulation and respiration are not seriously embarrassed.

Some Sources of Error in Laboratory Clinical Diagnosis. By Dr. Theodore C. Janeway.—The author considers that the first requisite for a diagnostician is not technical skill, but a judicial mind capable of weighing the value of evidence. Laboratory errors he divides into two classes: Those due to the methods used or to faulty technique, and those due to inaccurate reasoning from accurate results. In connection with tests for albumin in the urine, he mentions, as the most conspicuous error in technique, failure to filter the urine. In ring tests there must be a sharp line of demarcation between the solution and the reagent. The presence of bile or of urates in large amount renders Heller's test almost useless. Heller's reaction may take as many as fifteen minutes to develop, and the tubes should not be discarded within that time. In the author's opinion, the heat and acetic-acid test in a proper light is the most delicate and the easiest of application. The absence of any haziness with this test is absolute evidence of the absence of albumin. A very slight haziness is probably due to nuclealbumin and is of no significance. Fehling's solution is the most delicate test for sugar and certainly the most useful for just one purpose—to exclude its presence. No reduction with Fehling's solution invariably means no sugar, a reduction merely indicates the necessity for applying further tests. Quantitative urine analysis demands a sample of mixed twenty-four-hour urine, and even the most ordinary test is of little value if made with the urine passed at one time alone. In the use of the urinometer one must not neglect to make the correction necessary for changes in temperature. The Ehrlich diazo-reaction should only be considered as corroborative evidence of typhoid when found in the first week or ten days of a febrile affection. No error could be greater than to consider any urine examination complete without the use of the microscope. In the examination of sputum for the tubercle bacillus, any of the common staining methods needs only to be used accurately to give satisfactory results, but careless staining is a simple waste of time.

Philadelphia Medical Journal, May 4, 1901.

Puerperal Polyneuritis and Poliomyelitis. By Dr. James Stewart.—An interesting clinical and pathological article, which must be read in its entirety to be of value.

Localization of Sound and its Bearing on Hearing, Especially in Unilateral Deafness. By Dr. B. Alex. Randall.

The German Clinics of To-day. By Dr. John C. Hemmeter.—The author regards as one of the predominant features of the therapeutics in the German clinics the fact that the personality of the patient, not the conception of the disease, is put in the foreground of treatment. Another feature is the tendency to make use of a large variety and many methods for the relief of suffering and the cure of disease. In no other civilized nation in the world is diet treatment or nutritional therapeutics made the object of such thorough scientific investigation

as in Germany. Among newer tendencies issuing from the German clinics is the participation of internal medicine in the humane and social duties of our present age. Great interest is manifested in hydrotherapeutics, also in aërotherapeutics, the treatment by hot and cold air, by gymnastics, and massage. The representative German clinic of to-day is no longer under the ban of pathological anatomy, but its highest aim is the perfection of treatment, to help and to heal.

Volvulus and Intussusception of Meckel's Diverticulum. By Dr. Joseph McFarland.

Deaths from Anæsthetics. By Dr. D. H. Galloway.—The author asserts of deaths from anæsthetics that the profession regards them with an apathy which seems born of a belief that they are inevitable, and that there are no means at hand for lessening the number of such deaths. He gives a number of instances in which almost criminal carelessness was shown in administering the anæsthetic, and he makes the assertion that, though many operations are practically devoid of danger, no anæsthetic is ever administered without jeopardizing the life of the patient. He believes that the responsibility for these deaths lies in part with the surgeons, and in part with the medical colleges, which fail to lay stress upon the importance of the anæsthetizer's duties.

Esophoria, or Latent Squint. By Dr. Francis Valk.

Strangulated Hernia. By Dr. Walter Lathrop.—In these cases, according to the author, the mortality is due to delay in operation, and to unnecessary taxis. Taxis is never free from danger, and its use should be discouraged save in emergencies. Strangulated hernia is invariably fatal, unless relieved, and early operation will nearly always succeed, and life be saved.

Ammonium Persulphate Solution. A New Decolorizing Fluid for Staining Spores and Sputum. By Dr. Robert L. Pitfield.

Lancet, April 27, 1901.

The Sometimes Successful Treatment of Cases of Apparently Incurable Blindness. By Dr. C. B. Taylor.—The author states that it has been his good fortune on many occasions to restore sight to persons who were believed to be incurably blind, this end being obtained by means not usually adopted in such cases. The cases comprise patients who have recovered after many years of apparently hopeless blindness, others who have suffered from, and under treatment have recovered from, the effects of neuroretinitis, iritis with diffuse scleroderma, hyalitis, detached retina, atrophy of the optic disk, and the results of destructive inflammatory and degenerative changes. As to remedies outside the usual routine, he places, first, electricity—static, faradaic, and galvanic; second, mercury, either alone or in combination with other drugs; third, derivatives, vascular, nervous, or both; and, lastly, persevering treatment on these lines, with such operative procedures as may be indicated in each individual case, so long as there is the least chance of benefit or any eye left to be operated upon. Mercury may be administered by the mouth, the skin, or by subconjunctival injections. For the last purpose the author prefers the cyanide, the injection of which may be rendered painless by the addition of a small portion of acoine. Among the derivatives, the author gives first place to bloodletting; he holds that venesection has fallen into ill-deserved disuse. He also recommends the use of counterirritation in the form of setons, blisters, etc.

On Two Cases Bearing upon the Question of the Limitations of Enterectomy. By A. E. Barker, F.R.C.S.—The author reports two successful cases of enterectomy, which bear upon the question of the limitations of that operation. The first case was that of a woman, aged fifty-eight years, who was operated upon for annular carcinomatous stricture of the colon, four and a half inches of the gut being removed. The interest of the case lies in the fact that the patient suffered from diabetes, the urine containing 6.6 per cent. of sugar at one time. Yet she recovered perfectly from the operation, the only complication being slight sloughing of the omentum. The second case was that of an extremely feeble old woman, aged seventy-six years, suffering from a strangulated ventral hernia. At the operation, five and a half feet of gangrenous small intestine were removed. The patient made an uninterrupted recovery notwithstanding her extreme debility. The article closes with a list of cases (twenty-seven in all) of successful resection of the bowel, which the author has collected from the literature. In twenty cases more than one metre of gut was removed, in five more than two metres, and in two more than three metres. It would appear that about two metres of small intestine, say six feet, may be removed without any serious damage to the subsequent assimilative powers. In younger patients a compensatory hypertrophy may take place in the small bowel left behind.

On Hour-glass Stomach, with List of Six Cases Operated upon by the Writer, and a Tabulated List of All Cases in which Operations have been Performed. By B. G. A. Moynihan, F. R. C. S.—By "hour-glass" stomach is understood that condition of the stomach in which the viscus is divided into two cavities, usually of unequal size. It may be congenital or acquired, but, while most authorities hold the former variety to be the more common, the author states that congenital hour-glass stomach is certainly rare and not improbably mythical. The acquired form may be caused by: (1) Perigastric adhesions, the results of a perforated gastric ulcer, hepatic bands, and other causes; (2) ulcer with local perforation and anchoring of the stomach to the anterior abdominal wall; (3) circular ulcer with subsequent cicatricial contraction and induration; (4) cancer of the stomach. The characteristic signs which may, singly or in association, be present, are: (1) Disappearance of fluid introduced through the stomach tube; (2) after cleansing of the stomach by lavage, a sudden gush of putrid, sour food; (3) "paradoxical dilatation," succussion splash in pyloric cavity after siphonage of the cardiac loculus; (4) distention of cardiac loculus; its gradual subsidence, and concomitantly the distention of the pyloric loculus; (5) during this period a gurgling, forcing sound heard over, or near, the middle of the stomach; (6) on distention with carbonic acid a large increase in the thoracic area tympanitic on percussion, and a slight distention of the pyloric loculus; and (7), rarely a sulcus may be seen on inflating with carbonic acid.

The following operations are practised in cases of hour-glass stomach: (1) Gastropasty, with or without resection of the ulcer; (2) gastrogastrostomy or gastro-anastomosis; (3) gastro-enterostomy; and (4), partial gastrectomy. The author gives a table of thirty-two cases collected by him from the literature, and also reports a series of six cases operated on by himself, all of which were successful and resulted in recovery.

Reversed Pulsus Paradoxus Due to Aneurysm of the Aortic Arch. By J. Hay, M. B.—The author reports a case of aneurysm of the aorta, in which the radial pulse was markedly affected by the patient's respiration. There was a marked diminution of the volume of the pulse with expiration, and the sphygmogram showed the presence of a definite anacrotic wave, the position of which in the upstroke of the tracing varied with the respiratory variation. The rhythmical variation in the pulse was considered to be due to a mechanical cause, probably some kinking of the innominate artery during expiration, as the chest wall descended.

Case of a Parasite—"Argas (or Ornithodoros) Mèg-nini" (Dugès)—in Each Ear. By Dr. J. C. Simpson. (*With a Note on the Anatomy of the Specimen.* By E. G. Wheeler.)—The authors report the occurrence in both ears of a patient, of a tick of the above-mentioned genus. The parasites were attached to the tympanum, and were easily killed by the use of pledgets of cotton soaked in chloroform. There was no visible injury to the drum of either ear.

A Case of Belladonna Poisoning; Morphia Used as an Antidote. By P. D. Strachan, M. B.—The author reports the case of a boy, aged five years, whose mother had given him by accident a large tablespoonful of glycerin of belladonna. The child soon became wildly delirious and violently restless, but the movements were at no time convulsive. The face was flushed, the respiration rapid, and the pupils widely dilated. The stomach was washed out and a quarter of a grain of morphia given hypodermically. The delirium continued through the day, and the morphia was repeated in eight hours. The next morning the child woke apparently well. The case illustrates the tolerance of the child for belladonna and the efficiency of morphia as an antidote. One tablespoonful of the glycerin of belladonna contains one grain of atropine. No rash at any time appeared upon the body and there was no peeling of the skin. Treatment was not begun until five hours after the poison was taken.

Dermatitis from Arsenic in Stockings. By Dr. F. W. Tunnicliffe and O. Rosenheim, F. C. S.—The authors report two cases of dermatitis of the legs, in both of which they were able to detect arsenic in the black stockings worn by the patients. Sodium arsenate is extensively used as a fixing agent for mordants, in dyeing processes. In Sweden, Austria, and Germany, there are laws regulating the use of such arsenical mordants.

Tetanus Puerperalis. By Dr. K. Das.—The author has collected from the literature sixty-eight cases of puerperal tetanus; of these only five recovered. In regard to treatment, the following points must be looked to: (1) The destruction of the bacteria at the seat of infection by thoroughly antisepticizing the parturient canal; (2) the elimination of the toxins already absorbed, by purgation and intracellular injection of saline solutions; (3) the overcoming of the symptoms induced by the action of toxins—this is accomplished by isolation, quiet, and large doses of chloral; and (4), the neutralization of the poison already absorbed and immunization of the body after local infection has taken place. While antitoxine treatment has reduced the mortality of tetanus as a whole from ninety to forty per cent., yet the puerperal cases, taken separately, show no improvement in the percentage of recoveries.

Mercury and Iodide of Potassium Internally Given with Pilocarpine Hypodermically in Disease of the Eyes. By Dr. G. H. Burnham.—The author advocates this combined form of treatment in cases of inflammatory sclerokeratitis and sympathetic ophthalmia, and cites two illustrative cases. The treatment may be said to owe its efficacy to its power of arousing to excessive activity, in a vigorous and sustained manner, the normal physiological processes in diseased tissues.

British Medical Journal, April 27, 1901.

Traps and Pitfalls in Special and General Practice. By Dr. J. D. Grant.

Remarks on the Training of Ophthalmic Surgeons. By Dr. A. F. Ferguson.

On the Advisability of the Inclusion of the Study of Anæsthetics as a Compulsory Subject in the Medical Curriculum. By Dr. D. W. Buxton.—The author advocates that the study of anæsthetics be included in the medical curriculum, and suggests the following: 1. That all medical students, before applying for final examination, be compelled to furnish evidence (a) of having studied the practice of some recognized anæsthetist, and the theory of anæsthesia, its physiology, pharmacology, and practice; (b) of having actually administered nitrous oxide gas, ether, and chloroform; (c) of having obtained a certificate of proficiency from some recognized teacher. 2. That the final examination of students should include one by which their knowledge of anæsthetics can be tested.

On Certain Practical Applications of Extract of Suprarenal Medulla. By E. A. Schafer, F. R. S.—The author suggests that a trial should be made of the extract of suprarenal medulla in all cases in which it is desired to strengthen or to induce uterine contraction. His observations show that it has a far greater power in causing contraction of the muscular tissue of the uterus, whether pregnant or non-pregnant, than any other drug. Since the active principle is unaffected by the gastric juice, it can be given by the mouth, but in *post-partum* cases it would be better to inject it directly into the uterine cavity. The solution recommended is an infusion of dry medullary substance, thirty grains to the pint of water. Another class of cases in which the extract may prove of the greatest value is those of sudden cardiac failure. In these cases the sterilized decoction, five grains to a fluid ounce, should be slowly injected into a superficial vein. Remarkable results have been seen to follow the application of this method to animals in which the circulation had apparently entirely ceased. The material used consisted of the separated, healthy medulla of the suprarenal capsules of the ox or sheep, rapidly dried in thin layers at a temperature of not more than 50° C., then powdered and kept in well-stoppered bottles. A dose of five grains of the dry medullary substance may be introduced into a vein without fear of deleterious results.

Suprarenal Gland Extract in the Epistaxis of Hæmophilia. By Dr. D. McKenzie.—Since suprarenal extract checks hæmorrhage by inducing contraction of the unstriated muscle fibres in the walls of blood vessels, it would be reasonable to suppose it to be of little value in hæmophilia, which is associated with congenital hypoplasia of the vessel walls, including, of course, the muscular elements. Yet the author reports a case of typical hæmophilia, occurring in a boy aged thirteen years of age, and having a well-marked family history of hæmo-

philia, in whom a severe epistaxis was immediately checked by the application of suprarenal extract, after all other remedies had failed.

The Dietetic Value of Sugar. By Dr. H. W. Gardner.—The author calls attention to the great change that has taken place in our views as to the value of sugar as a food. Formerly it was looked upon with great disfavor; it was supposed to injure the teeth, to be constipating, productive of flatulence, etc. Nowadays, sugar has come to be looked upon almost as a necessity, and certainly as one of the most valuable articles of diet. The great increase in our consumption of sugar is due to its cheapness. Great Britain consumes annually eighty-six pounds of sugar per head of population; the United States comes next, with sixty-five pounds; in fact, the Anglo-Saxon may be distinguished as the sugar-eating race. The chief points about sugar as a food are: (1) It is easily digested and absorbed; (2) it is readily stored up as glycogen, forming a reserve of force-producing material; (3) it is in this form readily available when required; (4) it becomes completely oxidized without any waste and leaves no residue. Under certain circumstances it can also be converted into fat and stored away for future use.

It has been found that the addition of sugar in generous quantity to the diets of athletes and soldiers enables them to do more work with less exhaustion. It does not seem improbable that the increasing height and weight and the improving health of the English people during the last half century are at least to some extent due to that greater consumption of sugar that has been rendered possible by its cheapness. Alimentary glycosuria must always be borne in mind. If given in too large quantities, sugar can no longer be assimilated, and appears in the urine. Cane sugar is also apt to cause an undue secretion of mucus which may cause trouble. It has been the custom to countermand sugar in rheumatism, but the author is not at all sure that this is not merely prejudice. In gout the indication is more clear; those who are gouty and fat must avoid it like poison, but those who are gouty and thin may take sugar within certain limits.

A Preliminary Note on the Hibernation of Mosquitoes. By Dr. H. E. Annett and J. E. Dutton, M. B.—The authors have investigated the subject of the hibernation of mosquitoes, and state that they have been able to find adult mosquitoes (*Culex* and *Anopheles maculipennis*) in damp barns and cellars throughout the winter. Among the large numbers of mosquitoes of both genera collected by them, a male has never been found; moreover, all the females had been fertilized. When such adult females were fed upon blood in a warm room, they invariably laid eggs between the fifth and the eighth day. The authors' observations differ markedly from those of Wright, who has been unable to find adult mosquitoes in winter, and who attributes the continuance of the species solely to the great resistance to cold exhibited by the larvæ, which remain alive all winter. A number of the adult anopheles collected by the authors were kept in a damp cage for a month at a temperature of 5° to 10° C.; although no food was supplied, only two or three of them died. During the coldest weather the attitude both of *Culex* and *Anopheles* was peculiar and characteristic. The under surface of the thorax and abdomen was applied closely to the walls, the legs being stretched straight out, at right angles to the body. The character-

istic attitude of anopheles (at an angle to the surface) was entirely absent. Many of the culex were wholly enveloped in a thick mould, thus fixing them in the described position.

Centralblatt für Gynäkologie, April 13, 1901.

Cure after Operation for Carcinoma of the Uterus.—

Dr. J. Pfannenstiel reviews this subject exhaustively. The involvement or not of the parametrium and the character of the neoplasm must be considered when operative cases present themselves. The soft and early forms of the disease offer a better prognosis than the hard and older forms. Pregnancy or its future possibility must not be considered in the face of so serious a disease; but since metastasis in the ovary from a cancer of the cervix is unknown, the ovaries had better be retained in women who have not yet reached the menopause. The proportion of women who remain well after vaginal extirpation of the uterus is between seven and ten per cent. of all cases. Cancer of the body of the uterus gives the best prognosis. Cervical cancer, too, offers a better prognosis than that of the vaginal portion. By the use of clamps, the prognosis has been somewhat improved, since it allows of more thorough extirpation of diseased tissue in the circumvaginal and parametric tissues. Concerning the newer abdominal operations, the author says importance must be attached not only to the removal of glands, but also to the cleaning out of the parametrium, especially the parametric tissues lying in the neighborhood of the cervix. Pfannenstiel believes in limiting laparotomy in these cases to those instances in which the vaginal operation cannot be carried out in the ordinary manner. He thinks that the future cure of uterine carcinoma lies more in the early diagnosis of the disease than in improved technics, and he emphasizes the fact that it must not be forgotten that cancer of the uterus is not a disease of old age only, carcinoma of the vaginal portion, especially, occurring not infrequently between the twentieth and thirtieth years.

Expulsion of the Placenta by External Manipulation.—Dr. W. Zangemeister uses this method of expelling the placenta. In an interval of pain, the uterus is squeezed by the fingers at different places on the sides, anteriorly and posteriorly, sufficiently strongly to make indentations. This is repeated during two or three intervals. By this means the placenta becomes loosened from its site so that it can be easily expressed after two or three good contractions during a pain. Inversion is impossible by this method, as the indentations are not made at the top of the fundus, but at the sides, in front and behind only.

Münchener, medicinische Wochenschrift, April 9, 1901.

Blood Transfusion.—Professor August Bier has been employing the transfusion of lamb's blood in cases of malnutrition from various causes. He uses this blood, defibrinated, because of the intense reaction it occasions. It is injected into an artificially distended vein by means of an aspirating syringe. The action of the transfused blood is to produce hyperæmia resulting from capillary stasis, and a serous filling of the entire body. This is probably most intense in the diseased organs. It, further, stimulates metabolism and the appetite. The high "transfusion fever" the author regards as important and favorable. The changes in the composition of the blood occasioned by the transfusion, the author regards as therapeutically valuable. He has used it satisfactorily

in cases of sacro-iliac tuberculosis, tuberculosis of the bladder and testicles, of the lungs, of the knee-joint, and of various internal organs, in lupus, and in cachectic cases generally. There was always a temporary improvement.

Treatment of Gunshot Wounds of the Abdomen.—

Dr. Walther Petersen says that in every case the mere suspicion of perforation should lead to immediate operation, since delay is much more dangerous than an exploratory operation. Expectant treatment should be allowed only when the most experienced observation is possible.

Experiences in the Boer War in Bullet Injuries and Asepsis.—Dr. Eduard Sthamer reports his success in the field with aseptic measures only in wounds due to bullets. Antiseptic treatment was found to be inferior.

Multiplicity of Primary Malignant Tumors. By Dr. Nehr Korn.

Studies on Inflammation of Serous Membranes. By Dr. R. Heinz.

Two Cases of Embolism of the Abdominal Aorta.—Dr. C. Bühner reports two cases of mitral stenosis with thrombosis of the pulmonary artery and embolism of the abdominal aorta.

Value of Glutoid Capsules in the Diagnosis of Intestinal Disease. By Dr. Friedrich Fromme.

Bismuth Poisoning.—Dr. F. Mühlig reports the case of a young man whose burns were thoroughly powdered with subnitrate of bismuth. A week later the entire mouth was of a bluish-gray color, swollen, and ulcerated in places. Fœtor was marked and the mouth could be opened only with difficulty. He advises caution in the external use of the drug.

Casuistic Contribution to the Study of Benign Stenotic Diseases of the Œsophagus. By Dr. R. Schütz.

Treatment of Pertussis.—Dr. Gustav Spiess recommends the use of orthoform in an insufflator for the purpose of anæsthetizing the mucous membrane of the larynx and respiratory passages to reduce their irritability.

A Case of Unilateral Dislocation of the Lower Jaw. By Dr. M. Karehnke.

Riforma medica, March 12, 13, 14, 15, and 16, 1901.

Experimental Researches on Serumtherapy in Tetanus. By Dr. Guido Tizzoni.—The author compares the efficiency of his own serum against tetanus with that of Behring's and with other similar preparations. His conclusions are as follows: The curative value of antitetanic serums varies to a great extent. The first in point of efficiency is Tizzoni's, then comes Behring's, and then, at a great distance, comes the English serum. The French preparation must be given the last place. The difference between the author's serum and the other preparations is as follows: As compared to Behring's, the efficiency of Tizzoni's serum is as 2:1, as compared to the English serum as 10:1, and as compared to the French serum the difference is still greater. The curative value of a serum has no relation to its antitoxic power *in vitro*. This article is a contribution to the controversy between Tizzoni and Behring, as to the therapeutic value of the Italian and German antitetanic serums.

March 19 and 20, 1901.

Researches on Nephrectomy. By Dr. Antonio Zappulla.—Experiments on dogs show that these animals can continue to live when one half, or even more, of one kid-

ney has been excised and the other kidney completely removed, either before or after the resection of the first. Life continues in these circumstances "in the best conditions." The author announces his intention of publishing histological studies upon the question as to the nature of the regeneration of renal tissue after such resections.

March 21, 1901.

On the Time Relations between the Cardiac Murmurs and the Sounds of the Heart. By Dr. Giuseppe Polacci.—In insufficiency, the murmur occupies the entire phase of the cardiac cycle to which the abnormal sound belongs, and then indicates an advanced state of the regurgitation. When a murmur occupies only a part of the phase (systole or diastole) to which it belongs, it should be distinguished by the terms (suggested by Rummo) protosystolic, mesosystolic, and telesystolic; protodiastolic, mesodiastolic, and telediastolic, according to the portion of the systole or diastole which they occupy. Mesosystolic and telesystolic, and mesodiastolic and telediastolic murmurs always indicate a mild form of insufficiency, while protosystolic and protodiastolic murmurs always stand for advanced stages of endocarditis. The time relations of a murmur should therefore be minutely observed, for they indicate more clearly than the intensity and the transmission of the sound the stage of endocarditis with which we are dealing.

Gazzetta degli ospedali e delle cliniche, February 17, 1901.

On the Variations in the Alkalinity of the Blood in Fever. By Dr. Giuseppe Brunazzi.—Accurate chemical analyses and a comparison of his own results with those obtained by Malinconico furnish a basis for the following conclusions on this subject: The diminution in the alkalinity of the blood begins at the onset of fever and continues to progress with the rise of temperature, although it is not exactly proportional to the degree of pyrexia. This diminution is, therefore, not the result of the rise of temperature, but of metabolic changes which take place in the tissues in fever.

Some Changes in the Blood Resulting from Chloroform Anæsthesia. By Dr. Giovanni Benassi.—The author has found that chloroform anæsthesia produces certain changes in both red and white blood cells. The number of both erythrocytes and leucocytes is diminished, but the diminution is not in proportion with the duration of the anæsthesia, nor with the quantity of chloroform administered. The proportion between the red and the white cells is altered after chloroform narcosis, the white cells being diminished in greater numbers than the red. The alterations in the form of the red cells are proportionate to the duration of the administration and to the amount of anæsthetic used. The length of time required for the disappearance of all the alterations caused by the inhalation of chloroform is also in proportion to the duration of the anæsthesia and with the amount of anæsthetics employed. The changes in shape on the part of the red cells are manifold in character, the cells assuming stellate, cylindrical, or muriform outlines.

The Treatment of Pityriasis Capitis. By Dr. Andrea Rossi.

A Typical Case of Uterine Cough. By Dr. Salvatore Satullo.—In this case the cough is supposed to have de-

pended on a uterine affection, for it disappeared so soon as the lesions in the uterus were removed by treatment. The patient was a primipara, aged twenty-nine years, who had been suffering from a hard, dry cough for five months. The cough was very troublesome, and was occasionally accompanied by vomiting. The thoracic organs were found to be perfectly normal, as were also the larynx, pharynx, and ear. The patient had had menorrhagia for five months, a purulent discharge from the vagina, and attacks of pains in the back and loins. This attracted the author's attention to the genital organs, and he found that there were erosions upon the cervix, and that a uterine polyp, of the size of a nut, protruded from the os. The uterine mucosa was the seat of a chronic endometritis.

Journal Akouscherstva i Gienskich Boliesney, January, 1901.

On Accidental Wounds of the Urinary Tract in Operations on the Pelvic Organs of Women. By Dr. A. P. Goubareff.—The author treats of the operative procedures required in cases where the surgeon accidentally wounds the ureter during an operation on the female pelvic organs. A knowledge of these measures is necessary in order to get out of the scrape without injuring the patient. Formerly the first impulse was frequently the removal of one kidney, or the sewing of the ureter into the vagina, or even into the abdominal wound. In some cases the injury to the ureter only becomes apparent after the operation, and it must be remembered that blood in the urine drawn by catheter does not necessarily mean a wound of the ureter. The modern surgeon, however, sutures the central end of the ureter into the bladder, when possible, or unites the cut ends of the ureters in one of a number of ways, which are described by the author.

Evolution and Determination of Sex. By Dr. N. Schipoff.—The author attempts to apply the laws of evolution to the study of the causes determining the sex of a fœtus. A highly interesting article, but one, unfortunately, not suited for abstracting.

Uterine Stones. By N. I. Ratchinsky.—A description of three specimens of uterine calculi, together with notes on the cases. In the first case the stone was of the size of two fists, and belonged to a patient aged sixty-one years. It was lodged above the posterior fornix, and pressed upon the rectum so as to hinder defæcation considerably. The stone was removed by Ott in 1896. This stone was connected with the uterus by means of a thin pedicle of connective tissue and muscle, and it was necessary to perform laparotomy in order to remove it, as it was too hard to be crushed. The tumor was a mass of connective tissue impregnated with lime salts. The second specimen was a submucous uterine fibroid impregnated with calcium salts, about the size of a hen's egg, adhering to the uterus by a thin pedicle, and discovered at an autopsy. The third specimen was an enlarged uterus discovered at an autopsy, which, on palpation, seemed to be filled with a number of stones rubbing against one another. These stones varied in size from that of a pea to that of a walnut; they were grayish-brown in color, and spongy in structure, resembling corals in shape. The inner wall of the uterus was irregular and faceted to correspond with the stones. At the fundus there was an opening in the uterine wall,

closed by a thin membrane of inflammatory exudate, through which a stone protruded.

An Old Case of Inverted Uterus Treated by Piccoli's Method; Recovery. By Dr. A. A. Dranitzine.—The patient was a woman, aged fifty-one years, who had been suffering from inverted uterus for over six years. In 1896, a fleshy tumor appeared externally, and the protrusion reached the size of a newly born child's head. The diagnosis of uterine polyp was made, and the growth was successfully removed. Soon afterward, another protrusion appeared, smaller in size, together with a continuous bloody discharge. The diagnosis was inversion of the uterus due to the polyp. Piccoli proposed an operative method for the reduction and fixation of an inverted uterus, which was employed in this case. After disinfection, the uterus was brought down by means of forceps and the cervix held by assistants exercising traction upon five silk sutures that had been passed through the ring. The posterior vault was opened with a broad incision, the index finger introduced, and the adhesions fixing the inversion separated. The posterior wall of the uterus was then incised from cervix to fundus, along the index finger which had entered the funnel from the peritoneal side. The uterus was then reinverted by traction of the internal finger and pressure of the external hand and the incision closed with interrupted sutures, and the pouch of Douglas tamponed with gauze. The results were satisfactory, and no recurrence of the inversion was noted.

On Fixation and Manual Dilatation of the Cervix in Chronic Inversion of the Uterus as Compared to other Methods of Treatment. By Dr. A. A. Dranitzine.—The treatment of uterine inversion may be summed up as follows: First, manual reinversion must be tried, and if this fails the colpeurynter and tampons must be resorted to, in order to secure slow reposition. If these fail, the conservative operation (see previous abstract) must be resorted to, and, in case of failure, hysterectomy may be performed as a last resort. The author concludes from a consideration of clinical data that the manual method is adapted to the reduction of the great majority of inversions, and that in case of need, it may be combined with colpeurynter. Even if colpeurynter or tamponing fail, the manual method should again be tried, for the gradual dilatation of the vagina and pressure upon the inversion are good preparatory processes for manual reinversion. In this connection the knee-chest position renders valuable services. The only contra-indication to manual reinversion is the presence of purulent inflammation in the uterus or in the other pelvic organs. The author reports a case of inversion in which the uterus was reinverted by manual reposition, but only after the cervix had been fixed by sutures held by assistants.

Autoplastic Method of Suturing a Vesico-vaginal Fistula. By Dr. A. A. Abrajanoff.

A Case of Vaginismus Secondary to Condylomatous Growths on the External Genitals of a Newly Married Woman. By Dr. N. E. Akatzatoff.

Vratch, March 10, 1901 (March 22, New Style).

Cases of Sudden Unconquerable Somnolence (Narcolepsy). By Dr. S. J. Seltzer.—This rare condition was first spoken of by Thumen and Frieker in 1841, but the first detailed description of cases was given by Geli-

neau in 1880. The latter gave the name narcolepsy to a peculiar state in which the subject was seized with sudden somnolence that could not be overcome, notwithstanding every effort of the will. The author presents the histories of four such cases, and concludes as follows from a study of these cases and of the literature of the subject: Sudden unconquerable somnolence may occur as an independent disease. As such it may originate under the influence of violent emotions, such as great joy, or, more frequently, great grief. It occurs for the most part in individuals with a limited mental development, and in persons who have been weakened by some other disease; possibly under the influence of the mental depression caused by a consciousness of the gravity of the disease. A change of scene and of the mode of life contributes to the recovery of such patients.

A Case of False Arteriovenous Aneurysm. Application of Suture to the Vein. By Dr. V. I. Lisiansky.—In this case there was an aneurysm of the femoral artery at its lower third, on the inner side of the lower portion of the thigh, and the aneurysmal sac communicated with the femoral vein. The aneurysm was exposed, the artery separated from the vein, and ligatures applied above and below the sac. The opening in the femoral vein was then closed by means of five interrupted sutures of fine silk, the distance between the sutures being about 0.3 centimetre. An ordinary surgical needle was employed, and the whole wall of the vein was pierced at each puncture. The aneurysmal sac, represented by the thickened sheath of the sartorius muscle, was then excised, and the wound sutured with interrupted sutures, leaving space for drainage. The recovery was perfect.

Cases of Extra-uterine Pregnancy. By Dr. B. A. Fratkin.—The author reports five cases of extra-uterine pregnancy, four of which occurred among six hundred pregnant women during the past two years and a half. From an analysis of the statistics of extra-uterine pregnancy collected by other authors, he concludes that this anomaly of gestation is more frequent now than it was ten or fifteen years ago. This increase cannot, in his opinion, be attributed entirely to improvement in methods of diagnosis. The indications for operation in case of rupture of the sac and hæmorrhage into the peritonæum are as follows: If the diagnosis of rupture is made, but no blood tumor is found, laparotomy is always indicated. If a hæmatoma is distinguished, and if it shows signs of increase, there is no choice but to operate. If the hæmatoma remains small, however, the operation becomes a matter of choice, although it shortens the duration of the disease to a great extent. An operation is also indicated in the presence of signs of suppuration or sepsis. Laparotomy is to be preferred, as a rule, to the vaginal route. An important point is the immediate compression of the uterine end of the salpinx so soon as the uterus has been drawn into the wound.

Poisoning with Cream Tarts in Kharkoff (concluded). By Dr. P. N. Laschienkoff.—The author's experiments showed that these tarts contained a highly virulent form of *Staphylococcus pyogenes aureus*. On investigation, the process of preparing the cream for these tarts was found to be anything but aseptic. The author recommends that confectioners be required to heat the cream for such tarts, with the requisite additions, to 80° or 90° C. for at least half an hour, and that the preparation and sale of cream tarts should be prohibited in warm weather.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE. SECTION IN PÆDIATRICS.

Meeting of March 14, 1901.

Dr. W. L. STOWELL, Chairman.

The Pathology of Typhoid Fever.—Dr. MARTHA WOLLSTEIN read a paper on this subject. She said that milk was a very important factor in the transmission of typhoid fever to children. The gastro-intestinal tract was the most frequent point of entrance for the typhoid bacillus, but the foetus had been known to be infected by the passage of the bacilli through the placenta. The bacilli had been found in the urine, in the blood, and in the rose spots. It was convenient, as regarded the intestinal lesions, to divide cases of typhoid fever in children as follows: 1. Cases without characteristic lesions. 2. Cases presenting few and limited lesions of the solitary follicles and Peyer's patches. 3. Cases presenting intestinal lesions fully as extensive as in the severest forms in adults. The red blood corpuscles steadily diminished from the onset of the disease to defervescence or the first week of convalescence. Inflammatory complications were associated with leucocytosis.

The Value of the Widal Reaction.—Dr. JOHN LOVETT MORSE, of Boston, read this paper. He said that, while the tendency abroad was to make use of a high dilution and employ a short time limit for the Widal reaction, in this country the preference was for a low dilution and a longer time limit. Out of 253 cases of clinically diagnosed typhoid fever observed last autumn at the Boston City Hospital, there had been ten cases in which the reaction had not been obtained. Two of these had evidently been typhoid fever, for one presented intestinal hæmorrhages, and the other the typical lesions of typhoid fever, at the autopsy. The dilution employed was one in ten, and the time limit half an hour. He thought one was justified in asserting that the Widal reaction was present in at least ninety-five per cent. of all cases, but that it seldom appeared before the second week of the fever, and might be delayed until convalescence. Typhoid fever could not, however, be excluded by a single negative test or even, absolutely, by repeated negative tests. If a positive reaction was obtained, it was proof of typhoid fever unless the person had previously had this disease. The most convincing proof of all of the presence of typhoid fever was a negative reaction followed by a positive reaction, a dilution of one in fifty being used. Of 164 cases of typhoid fever in children between the ages of two and thirteen years, 77 had given a positive Widal reaction. The reaction appeared to occur somewhat earlier in children and to disappear more quickly. This reaction was not quite so important in early infancy, because of the possibility of a previous foetal typhoid. Proof was not wanting of the transmission of the agglutinating power to the infant through the mother's milk, but it was quite evanescent in the infant when so transmitted.

Dr. W. P. NORTHRUP referred to the case of an infant of nine months, seen by him in hospital practice, in which no Widal reaction had been obtained, notwithstanding the fact that in the same hospital at that time there were three other members of the family sick with typhoid.

No typhoid bacilli could be found in the urine. The speaker added that, although 22,260 children belonged to the New York Foundling Hospital, and about 1,200 were farmed out in the suburbs of the city, not a single case of undoubted typhoid fever had been seen among these children in the many years of service of Dr. O'Dwyer, Dr. J. Lewis Smith, and himself.

Dr. DAVID BOVAIRD, JR., thought the different opinions expressed regarding the prevalence of typhoid fever among children could be reconciled on the ground that the prevalence of this disease among adults varied greatly in different localities.

Dr. JAMES J. WALSH said that he had seen typhoid fever in two children of twelve and fifteen years respectively. Both had given the Widal reaction, one on the twenty-sixth and the other on the twenty-eighth day, and both had had relapses. He thought the Widal reaction was rather one of immunity than one of infection.

Dr. E. LIBMAN said that he had done much work with the Widal reaction, and in three years had seen about seventy cases of typhoid fever in children, as determined by this reaction. The Widal reaction had proved especially useful in distinguishing between typhoid fever, pneumonia, and meningitis. He had made use of a dilution of one in twenty and a time limit of fifteen minutes, and since he had adopted the plan of growing the bacilli at 86° F. there had been a much larger proportion of Widal reactions noted.

Dr. MORSE said that he would hesitate to make the diagnosis of typhoid fever if there was an increase in the white blood corpuscles. He had not observed any special relation between the time of the appearance of the Widal reaction and the occurrence of relapses.

Letters to the Editor.

URETHRAL IRRIGATION.

WESTFIELD, MASS., April 15, 1901.

To the Editor of the New York Medical Journal:

SIR: Having read with interest a paper written by J. R. Eastman, M. D., published in your issue for April 13th, I wish to take exceptions to his remarks on Valentine's apparatus, with which he particularly finds fault.

1. The "force" is not regulated by raising and lowering the apparatus, but by the stopcock. Here let me say he has a new device for a stopcock.

2. I see nothing to be sterilized in the Valentine apparatus but the nozzles; these he sterilizes most thoroughly, and, furthermore, he never uses the same nozzle in a second case, before sterilizing. They are made of glass.

3. If the doctor knew that permanganate of potassium spoils in twenty-four hours, in solution, he would not speak of a "stock solution"; if the tablets are used and thoroughly "rubbed up" in a graduate, the objection the doctor finds will be fully dispensed with.

4. In reference to only irrigating the anterior urethra, if the doctor will lightly compress the urethra with the little finger, he will soon learn (by feel) when the fluid is at the "cut-off" muscle.

5. To gauge the pressure, this can be done by the pushing to and fro of the stopcock.

6. It requires about five seconds to fill the percolator, which, in my opinion, is quick time.

I can find no improvement in the doctor's apparatus

over Professor Valentine's. It reminds me of the old-time pocket-syringe treatment, the trouble-producer and, in fact, good for the specialist.

Being a former senior assistant to Professor Valentine, watching his untiring labors and efforts to produce an apparatus for the rapid cure (also positive) of gonorrhoea, I can speak with full knowledge of his apparatus. In conclusion, I wish to say that Professor Valentine will be pleased to send the doctor such literature as he has on the subject, and show his usual hospitality to the doctor if he is ever in New York. I wish to ask the professor's pardon for any error I may have made in my remarks as to his willingness to do as said above.

FRED. P. LOWENSTEIN, M. D.

Book Notices.

Aetiologie und Prophylaxe der Lungentuberkulose. Von Dr. J. RUHEMANN, Arzt in Berlin. Mit 13 Kurventabellen. Jena: Gustav Fischer, 1900. Pp. 88.

THE author regards other bacteria than the tubercle bacillus as concerned in the initiation of pulmonary tuberculosis, especially the influenza bacillus, although, of course, these cannot start the disease without the aid of the tubercle bacillus. They furnish complications and keep them active, thus prolonging a disease which might, under suitable conditions, yield to treatment.

The first four chapters of the book deal with the ætiology of the disease in a striking and convincing manner. The last chapter treats of its prophylaxis, and is eminently readable by reason of its vigorous style and excellent condensation.

Burdett's Hospitals and Charities, 1900. Being the Yearbook of Philanthropy and the Hospital Annual. By Sir HENRY BURDETT, K. C. B., etc. London: The Scientific Press (Limited). New York: Charles Scribner's Sons, 1900. Pp. 1051.

THIS volume sustains the reputation of its predecessors and affords information that is nowhere else available. It is the ambition of the editor of this unique publication to include data from all English-speaking countries, and he has occasion to say that "there is in the United States of America a literature of the highest value which is confined entirely to pamphlets. Some of the ablest writing in the English language we have found in pamphlets of the sort we have in mind, and we should immensely appreciate the cooperation of any residents in the United States who would kindly procure and dispatch every pamphlet of the kind which comes under his notice, so that the collection we have commenced may ultimately be as complete as possible." It is to be hoped that those of our readers who may have such pamphlets, or who are connected with hospitals that publish reports, will comply with this request.

Inorganic, General, Medical, and Pharmaceutical Chemistry. Theoretical and Practical. A Text-book and Laboratory Manual containing Theoretical, Descriptive, and Technological Chemistry; Class Exercises in Chemical Equations and Mathematics; and Practical Manufacturing Processes for Five Hundred Chemical Preparations, with Explanatory Notes. By OSCAR OLDBERG, Pharm. D., Professor of Pharmacy, Northwestern University, Chicago, etc. In Two Volumes. Chicago: Chicago Medical Book Com-

pany, 1901. Volume I, pp. xii-522. Volume II, pp. viii-655.

THESE two volumes form a practical guide to the study of inorganic chemistry, the first dealing with the theoretical and descriptive part of the subject, the second forming a complete laboratory manual. The work appears to be thorough and entirely modern in its views, and it will no doubt become popular with students when its merits are known.

Ueber die vom Processus vermiformis ausgehende diffuse eitrig Peritonitis und ihre chirurgische Behandlung. Von Dr. ALI KROGIUS, Dozenten der Chirurgie an der Universität Helsingfors (Finland). Mit 43 Kurven im Text. Jena: Gustav Fischer, 1901. Pp. 240.

It is interesting to note the gradual acceptance by Continental, especially German, writers of the American views on appendicular inflammation. It has been, indeed, a slow process; but it is gradually bearing fruit and at the present day the resistance to operation is growing less and less as the subject is more thoroughly understood. In the present volume the author lays down authoritative rules for surgical intervention, although he has limited himself somewhat generally to the treatment of peritonitis as a sequel of inflammation of the vermiform appendix. The work opens with a long historical account of the entire subject of appendicular inflammation and its treatment, in which our own writers are, naturally, frequently cited. The author favors unreservedly the operative treatment of diffuse purulent peritonitis which results from a ruptured appendix, although the mortality in his fifty cases is extremely high, not so high, however, as if the operation had not been performed. The book is a good example of thoroughness and is worth careful perusal. The chapters on classification, diagnosis, and ætiology are carefully prepared and mark the work as complete.

The Treatment of Fractures. By W. L. ESTES, A. M. M. D., Physician and Surgeon-in-Chief of St. Luke's Hospital, South Bethlehem, Pa. New York: International Journal of Surgery Company, 1900. Pp. 216.

It is always refreshing to find a work by the hand of an author whose wide experience has qualified him to present to his readers an original treatise which is so exceptionally free from padding and unnecessary detail, and yet leaving us nothing ambiguous to ponder over, but in its stead supplying us with all the essential and desirable information possible in so small a volume. The writer states in his preface that he has drawn freely from modern authorities for ideas and suggestions, but further says that the methods and measures laid down have been the result of a large hospital experience extending over the past fifteen years. It is noteworthy that the writer has given space to the mechanics of fractures in general only where it has been found necessary to elucidate the treatment, the latter, as suggested by the title, being the main object of the book.

The author has been most judicious in the arrangement of the work. He first considers the "first aid and transportation," a subject to which, as a rule, too little space is given. The importance of it is well illustrated in this chapter. We find under the same heading mention of a number of simple and clever devices for the prevention of further injury to the affected part and further suggestions leading to the greater comfort of the patient.

during his transportation. The advice to immediately apply a permanent splint whenever it is practicable, preferably plaster-of-Paris, is worthy of special comment; as the author states, there is nothing to fear from the secondary swelling if the splints have been properly applied.

Among the many interesting chapters may be mentioned that on fractures of the vertebræ; here the author has the opportunity of exhibiting his intimate knowledge of these fractures, permitting his reader to derive the benefits from his invaluable experience and mature judgment. Almost equal interest will be found in the chapters that follow, each of which makes manifest the desire of the author to place at the disposal of his readers only such subject-matter as is pertinent and desirable.

BOOKS, ETC., RECEIVED.

The Theory and Practice of Military Hygiene. By Edward L. Munson, A. M., M. D., Captain, Medical Department, United States Army. Illustrated by Eight Plates and nearly Four Hundred Engravings. New York: William Wood & Company, 1901. Pp. xii-971.

A Text-book of Mechanotherapy (Massage and Medical Gymnastics) Especially Prepared for the Use of Medical Students and Trained Nurses. By Axel V. Grafstrom, B. Sc., M. D., late House Physician, City Hospital, New York, etc. With Eleven Pen-and-ink Sketches by the Author. Philadelphia: W. B. Saunders, 1900. Pp. 5 to 139.

Vorlesungen über die pathologische Anatomie des Rückenmarks. Unter Mitwirkung von Dr. Siegfried Sacki, Nervenarzt in München. Herausgegeben von Dr. Hans Schmaus, a. o. Professor u. i. Assistant am patholog. Institut in München. Mit 187 theilweise farbigen Textabbildungen. Wiesbaden: J. F. Bergmann, 1901. Pp. xxi-589.

Pathologie und Therapie der Herzneurosen und der functionellen Kreislaufstörungen. Von Dr. August Hoffmann, in Düsseldorf. Mit 19 Textabbildungen. Wiesbaden: J. F. Bergmann, 1901. Pp. ix-367.

Verhandlungen der siebzehnten Versammlung der Gesellschaft für Kinderheilkunde in der Abtheilung für Kinderheilkunde der 72 Versammlung der Gesellschaft deutscher Naturforscher und Aerzte in Aachen, 1900. Im Auftrage der Gesellschaft herausgegeben von geheime Sanitätsrath Dr. Emil Pfeiffer, pract. Aerzte in Wiesbaden. Mit einer Tafel. Wiesbaden: J. F. Bergmann, 1901. Pp. xiii-260.

Bericht über die acht und zwanzigste Versammlung der ophthalmologischen Gesellschaft. Heidelberg, 1900. Unter Mitwirkung von E. von Hippel und A. Wagenmann. Redigirt durch W. Hess und Th. Leber. Mit 17 Tafeln und 8 Abbildungen im Text. Wiesbaden: J. F. Bergmann, 1901. Pp. ix-242.

New Inventions.

DR. CORNING'S INSTRUMENT FOR SPINAL ANÆSTHESIA BY CATAPHORESIS.

THE accompanying cut was accidentally omitted from Dr. J. Leonard Corning's article on Spinal Anæsthesia by Cataphoresis, published in our issue for May 4th.

A, the outer (insulated) tube; B, the inner tube; C, D, the binding-posts; E, the bulb of the outer tube.

Miscellany.

Some Medical Aspects of Napoleon's Campaign against Russia.—Some years ago Dr. Achilles Rose published in the *New Yorker medicinische Monatsschrift* a number of interesting extracts from a Latin dissertation by C. J. von Scherer, a surgeon attached to the corps of Würtembergians, and from a book by a German officer of the Westphalian corps. We now reproduce the substance of them in English.

In the beginning of May, 1812, Napoleon's army arrived at the frontier of Poland, whence it proceeded by forced and most tiresome marches to the river Niemen, which forms the boundary between Lithuania and Poland, arriving at its borders in the middle of June. An immense body of soldiers met near the city of Kowno, crossed the Niemen on pontoons, and formed under the eyes of the emperor in endless battle line, on the other side of the river. The forced march continued day and night over the sandy soil of Poland. The tropical heat during the day and the low temperature at night, the frequent rain storms from the north, the camping on bare and often wet ground, the ever-increasing want of pure water and fresh provisions, the immense masses of dust which, like a cloud, hung over the marching columns—all these together had sapped the strength of the soldiers even in the beginning of the campaign. Many were taken sick before they ever reached the Niemen. The march through Lithuania was hastened as much as the march through Poland; provisions became scarcer all the time; meat from cattle that had suffered from starvation and exhaustion was for a long time the soldiers' only food. The great heat and the inhalation of sand and dust dried the tissues of the body, and the thirsty soldiers longed in vain for a drink of water. Often there was no other opportunity to quench the thirst than in the swamps. The officers were powerless to prevent the soldiers from kneeling down at the stagnant pools and drinking the foul water without stint. Thus the army,

tired to the utmost from over-exertion and deprivation and disposed to sickness, entered the land of the enemy. The forced marches were continued during the heat of the day through sand and dust until stormy weather set in with rain, followed by cold winds. With the appearance of bad weather a general diarrhoea, which had already been observed at the time of crossing the Niemen, showed itself with greater severity. Men were attacked so rapidly that in the midst of the march they had to leave the ranks. The route the army had taken from camp to camp was marked by offensive evacuations. The number of the sick became so great that they could not all be attended to, and medical treatment became illusory when the supply of medicaments was exhausted. Many were left behind and a large number died on the way. On post-mortem examination, nothing noteworthy was found in the intestinal tract.

The greater part of the army fought in vain, however courageously, against the extending evil. Soon the strongest constitutions succumbed. Naturally enough, there was wanting everything of which the sick were in need—vegetables, farinaceous food, and medicaments—and consequently there was no barrier against the spread of the disease, while at the same time the deprivations and hardships which had caused it continued and reached their climax. Of a morning there were often as many as thirty of the small Würtembergian corps who had died during the night, not only such as had come to the camp sick, but also many who the previous evening had been counted among the healthy. Many who apparently were strong were taken with sudden nervous exhaustion and were as if paralyzed, unable to stir. Then came vertigo, insatiable thirst, and pain over the eyes. They died suddenly without fever. They had a slow pulse, without any abdominal pain, and often died in a moment with perfect consciousness. The post-mortem examination of those who had died from dysentery revealed inflammation of the stomach and the larger intestine, especially the rectum. The intima of the stomach, of the duodenum, and sometimes of the whole intestinal tract was completely relaxed and atrophied. In some cases there were found small ulcers in the stomach, with dentated margins, especially in the fundus, and there were like ulcers in the rectum. In other cases there were found quite large ulcers extending from the stomach into the small intestine. They were from the size of a lentil to the diameter of half an inch, and occupied the different membranes; in extreme cases the muscularis and the mucosa, but only rarely the servosa. In many instances there were gangrenous patches. The gastric juice had a sour odor; the lower part of the liver was bluish and hardened, containing a bluish liquid; the gall-bladder was generally empty or contained only very little bile; the mesenteric glands were mostly inflamed, sometimes purulent.

During the advanced stage of the disease the patients suffered from gastralgia, were very hungry, longed for vegetable diet, but had no fever. Some would march, equipped with knapsack and arms, apparently in good spirits, but suddenly would succumb and die. Others, especially those of a strong constitution, would become melancholic and commit suicide. Immoderate use of liquor proved very disastrous.

On the way from the Niemen to the Düna three thousand sick men had to be left in the hospitals of Malaty, Wilna, Disna, Strizzowan, and Witepsk.

The number of deaths increased from day to day. In the hospital of Strizzowan, in which von Scherer served

six weeks, there were 902 patients. Of these, 310 died during the first three weeks; during the following three weeks, when better nursing and better means of treatment were obtainable, the number of deaths was only thirty-six.

The arrangements, which were made in haste during the march and called hospitals, had either no supply of drugs or only a very limited quantity. All that could be found in the shape of medicinal herbs in the fields or in the woods was made use of. Thus, they used, for instance, in the hospital of Witepsk, huckleberries and tormentilla root. When von Scherer organized a hospital in the castle of Strizzowan, he brought a large number of patients into a barn and two stables, and being without the necessary refreshments and drugs for them, he proceeded, not without difficulty and danger, to obtain some from the vicinity. During the first three weeks he gave partly as nourishment, partly as a medicament, the following plants which grow there, and sometimes with really good effect: *Cochlearia armoracea*, *acorus calamus*, *allium sativum*, *rhapanus sativus*, *menyanthes trifoliata*, and *salvia officinalis*.

During the following three weeks he received several thousand florins from General Count von Scheeler, with instructions to apply the sum toward ameliorating the condition of his patients. He procured eatables and drugs from great distances, namely, from the Polish cities, Mohilew, Minsk, and Wilna. Enabled now to give his patients proper diet and medicines, he had excellent results. Some of the convalescents had relapsed on the slightest provocation, such as the eating of potatoes, which grew abundantly in the vicinity of the hospital. They were eaten surreptitiously, often in large quantities, by some of the convalescents. Many who were on the way to recovery died in consequence of their imprudence; others suffered for a long time great weakness of the intestine.

Marvellous was the effect of mental emotions on the disease. Great fright or great joy caused a sudden cessation of dysentery. Surgeon-General von Kohlreuter during and after the battle of Smolensk, witnessed the great influence of mental emotion on diseases of the body. Of 4,000 Würtembergians who took part in that battle there were few who were quite free from dysentery. Tired and depressed, the army dragged along; but as soon as the soldiers heard the cannon at a distance, telling them the battle was beginning, they emerged at once from their lethargy; the expression of their faces, which had been one of sadness, changed to one of joy and hilarity. Joyful and with great bravery they went into action; the hope of relief from the depressing state of war revived body and mind.

During the four days that the battle lasted and for some days afterward dysentery disappeared as if banished by magic power. When the battle was over, and the deprivation was the same as before, the disease returned as severe as before—nay, even worse, and the soldiers fell into complete lethargy. Many convalescent improved but slowly from great emaciation. Most noticeable was a kind of despondency or, rather, mental indolence which persisted in the patients; even in officers whom von Scherer had known as energetic and cheerful men a certain moroseness and a remarkable indolence were observed.

In the battle of Borodino, the soldiers fought like maniacs, with a wild joy devoid of all human feeling. They attacked the enemy where they were the most numerous. In charging a battery they all sought to be

first, exposing themselves to the fire of innumerable cannon; over heaps of corpses they stormed the batteries of the enemy. This was not the work of health and strength, not the work of calm bravery, but the act of extreme despair. About a thousand Württembergians were wounded, and many had to undergo surgical operations. It is noteworthy that in those of enfeebled and in reduced general condition capital operations were unusually successful and more were saved than is usual under apparently more favorable circumstances.

After the battle the army marched to Moscow and remained there until October 19th. The condition of the men was not materially improved. They had arrived starving, without the necessaries of life, and the burning of the city deprived them of suitable winter quarters, of which they were in sore need. Although eatables saved from the fire were distributed among the soldiers, so that they had during the weeks they remained tea, coffee, meat, and bread in sufficient quantity and of good quality, dysentery continued and assumed in the majority of patients a typhoid character. Besides, real "typhus"* had now made its appearance in the army. Icterus, associated with gastralgia and feverish pulse, were among the first symptoms. The fever spread rapidly and added to the misery of the army. The large number of sick gathered in miserable places, the odor of the innumerable cadavers lying in the streets of Moscow, the fatigue and deprivation of the men—all this had prepared for the development of the disease.

After the retreat from Moscow had been decided upon, all the sick that could be transported were sent ahead on wagons under a strong guard. They were sent on the nearest road to Borodino, while the army took the road to Kaluga. Several thousand fever patients were left in Morkan. With few exceptions, according to later information, they all perished. Of those who, although attacked by the disease, had still strength enough to be transported on the wagons, quite a number recovered on the way, to become, later on, victims of the cold.

The army left Moscow after the middle of October. The weather was clear and the nights were cold. The road chosen was the one to Kaluga, and the march was a forced one. Near Maloijoroslawez a desperate engagement took place, in which the French cavalry sustained severe losses. The discipline which thus far had kept the army together was shaken, and irregularities of all descriptions began to take place. Officers and men alike, seeing the general helplessness, looked with despair into the future. Surrounded on all sides by the enemy, who pressed them severely, the men were forced to remain on the high road. Whoever absented himself from the road exposed himself to the alternative of being killed or taken prisoner. On the endless tract of devastated land, from Moscow to Wilna, one did not see a native for days or even one head of cattle. Cities and villages had been laid in ashes; every day the misery and distress increased. The provisions which the men had taken with them from Moscow were lost, together with the wagons, on the flight after the engagement of Moliojoroslawez, before the army had reached Borodino. The rations which the soldiers carried with them were eaten in the first few days, and after that there was complete want of food. The horses, which could not be fed, fell in great numbers on the road. From the last days of October until mid-December, when the army arrived at Wilna, horseflesh was the only food of the greater portion of the soldiers. Many did not get even this and died from starvation before the

great cold set in. The meat, however, which the survivors ate came from the starved and worn-out horses which had been unable to proceed further, or from such as had been lying dead on the road for a long time. With great voracity the soldiers threw themselves on the dead animals and fought with inhuman frenzy, disregarding all differences of rank and all military discipline, officers and men alike striving to secure some portion of the carcass, the heart, liver, and brain being the most preferred parts. The weaker had to be contented with any part. Many devoured the meat raw, while others placed it on bayonets and roasted it by a fire, eating it with the greatest relish, without any addition of condiments.

This was the sad condition when the great cold set in and brought the misery to its climax. During the last days of October, when the army hardly had reached Borodino, cold north winds came. On October 26th there was the first snowfall, and the snow made the way difficult to the utmost degree for the enfeebled army. The cold increased now from day to day, and it was already terrible for many to pass the night in the open air. Most of those who were unable to protect themselves by the warmth of a fire or by warm clothing had their limbs frozen. During the first days of November the thermometer had fallen to 5° F. Among the deleterious effects of the cold, mental derangements were noticed about this time. The first effect of the cold on the brain, which manifested itself even in the strong and healthy men, was loss of memory. At the very beginning von Scherer noticed many who could not name the best known and most familiar things, who even could not name the articles of food they were longing for most eagerly, or called them by a wrong name. Many forgot their own names and did not recognize their nearest friends and comrades. Others appeared altogether weak-minded, the facial expression being that of perfect dullness. Those who escaped the ill effects of the cold because of their strong constitution of body and mind were pained and horrified, in addition to their own misfortunes, to see the mental faculties of excellent men, otherwise full of will power, sometimes slowly, sometimes rapidly diminish and gradually degenerate into real lunacy, once in a while to brighten up for a moment only to sink down again.

The great cold enfeebled at first the brain of those whose health had been suffering before, especially of those who had suffered much from dysentery. Soon, however, with daily increasing cold, the influence of the low temperature made itself felt by every one. In consequence of the effect of the cold, the deeper-seated vessels of the brain and lungs were gorged, and the right heart was enlarged. In one case the autopsy revealed rupture of the blood-vessels of the brain: in most instances more or less serum was found in the sinuses. The corpses were white as snow, while the central organs in every autopsy were found full of blood. In the beginning, while the cold was still tolerable, the concentration of the liquids from the surface of the body into the central organs caused only slight changes in the functions of these organs, such, for instance, as difficult breathing, mental weakness, sometimes in greater, sometimes in less degree, numbness, indifference to external matters; in short, all that was called at that time the "Russian dunce," or "Russian dolt." The actions of these men gave evidence of complete paranoia and the highest degree of indifference. This condition may be compared to that of senility, when body and mind have been reduced again to the state of childhood. The bodies

*It is probable von Scherer means what we call typhoid fever.

of those who had suffered most from cold were as much wrinkled and parched as those of very old people. Men, before full of vigor in body and mind, hardened in the field, were tottering along, bent over a stick, lamenting and wailing like children. On the way they would beg for a piece of bread, and, if they received something to eat, real childish joy overcame them, bringing not infrequently tears to their eyes.

The features of these unfortunates were, according to the amount of suffering they had undergone, deadly pale and strangely changed. Youths looked like men eighty years of age, and their appearance was like that of cretins. The lips were bluish, the eyes dull without brilliancy and constantly in tears; the veins were small, hardly visible; the extremities were cold, the pulse could not be felt either at the wrist or at the temples; an almost invincible inclination to sleep prevailed. Often there happened, in the moment of sinking to the ground, paralysis of the lower extremities; shortly after this a few drops of blood from the nose indicated approaching death.

All bonds of brotherly love were undone; extinct was all human feeling. Upon anyone who sank down exhausted on the road the nearest comrades, the dearest relatives would throw themselves, to take possession of his garments, etc., leaving him naked on the snow, exposed to sure death. All that lived in the men was the instinct of self-preservation.

During the second half of November, still more during the first days of December and especially on the 8th, 9th, and 10th, when the army arrived at Wilna, the cold had reached the highest degree. During the night from the 9th to the 10th the thermometer was 40° F. below zero. The cold air caused severe pain in the eyes, similar to that brought on by heavy pressure. The eyes, which had been weakened already by the continued sight of snow, suffered thus very much. Many were blinded to such a degree that they could not see one step forward, could recognize nothing, and had to feel the way by means of a stick. Numberless men fell on the road and stiffened at once. During this period von Scherer observed that when those fell on the hard, frozen, ice-covered ground who had been suffering already considerably from cold, they died soon, in consequence, probably, of concussion of the spinal cord brought on by the fall, for suddenly general paralysis of the lower extremities, of the bladder, and of the sphincter ani occurred; urine and feces were involuntarily voided. Many, without falling, without suffering such a concussion, died from progressive paralysis which proceeded from the lower extremities. In others complete hemiplegia ensued, while the mental faculties remained intact up to the last moment.

Regimental Surgeon von Keller communicated the following case to von Scherer: "It was near Wilna, during the first days of December, in one of the coldest nights, when we were lying around a fire in the road, together with a number of German officers, when a military servant approached us, asking permission to bring his master, an officer of the guard, to our fire. We consented with great pleasure, and two men of the guard brought a tall and strong man of about thirty years of age and placed him between themselves on the ground. When the French officer learned that a surgeon was present, he narrated that something very strange had happened to him. Notwithstanding the great misery, he had been until now cheerful and well, but half an hour ago his feet had become rigid, he had been unable to walk farther, and now he had no longer any sensation from the

toes up to the thighs. I examined the case carefully. The feet were perfectly stiff, white as marble, and ice-cold. The officer was well dressed and, although in a most precarious condition, more cheerful than my comrades and myself. Soon he had a great desire to urinate, but was unable to do so. With great relish he ate a large piece of horseflesh which had been roasted, but complained soon of illness, and his hitherto cheerful disposition changed into greatest depression of mind. The urine was retained for several hours, which caused him great pain, but during the latter part of the night he passed involuntarily feces and a large quantity of urine. He slept a great deal, and his breathing was until then free, but when morning dawned he went into a comatose state, and with daybreak, before we left our camp fire, the strong man who eight or ten hours before had been in good health, had died."

Interstitial Keratitis in the Offspring of Syphilitics.

—Dr. Peter A. Callan (*American Gynecological and Obstetrical Journal*, February) concludes that the offspring of syphilitics show the evidences of the inherited taint in only a slight percentage of the cases; that is, if we except those children that die under five years of age. Only a slight percentage of such children develop interstitial keratitis. When the disease attacks one eye, all our treatment appears to be powerless to prevent its development in the other eye. We may possibly delay, but we cannot prevent, the outbreak of interstitial keratitis in certain cases.

A Wandering Letter from the United States to the Late Ernest Hart.—The following from the *West London Medical Journal* for April may possibly reach the eye of the sender of the letter, and is therefore republished:

"A curious letter was delivered the other day at the hospital. It bore the United States postmark, and was addressed to 'Dr. Ernest Hart, at one time ophthalmic surgeon to the West London Hospital.' I have no means of judging of the measure of the sender's expectations as to the proper delivery of the letter, but to save further speculation it may be pointed out that Mr. Hart ceased his connection with the hospital more than thirty years ago, and that he has been dead more than three years. If the sender of the letter should ever happen to see this paragraph, it may interest him to know that I forwarded his communication to Mr. Hart's widow. That ends my knowledge of the matter, because I have not had a reply."

The Legal Complications of Ovarian Grafting.—The *American Gynecological and Obstetrical Journal* for April, commenting editorially on a paper on Ovarian Grafting in the *Medical Record* for January 19th, by Dr. Robert T. Morris, says:

"Should some of these experiments result in pregnancy we should fancy certain not uninteresting medico-legal questions might arise, but we suppose this is one of the objections that Dr. Morris classifies as 'fanciful'; and when at last a real baby is produced from such a dual league it will be time enough to decide whether the infant belongs to the woman whose tissues, though cast upon a foreign shore, really sent it forth or to the woman whose uterus took the wanderer in and harbored it for nine weary months; and whether the second woman would be justified in a suit to recover rental: or, failing in that, in evicting the tenant before the lease should have expired."

Original Communications.

THE PATHOLOGY AND BACTERIOLOGY OF URETERO-INTESTINAL ANASTOMOSIS.

BY F. ROBERT ZEIT, M. D.,

CHICAGO,

PROFESSOR OF CLINICAL PATHOLOGY, BACTERIOLOGY, AND HYGIENE IN THE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL AND POST-GRADUATE MEDICAL SCHOOL.

(Concluded from page 761.)

Ureteral implantation into the rectum was done on 120 dogs (Martin, 76; Peterson, 44), of which number 101 died during the first forty-eight hours after the operation, of peritonitis, due to leakage of urine into

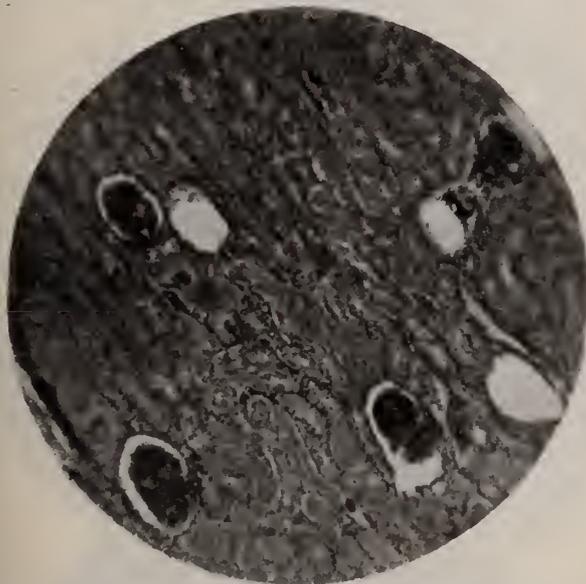

FIG. 9.—Implantation of both ureters into the rectum. The dog died, sixty days after the operation, of pyelonephritis of one kidney. Cloudy swelling and necrosis of the epithelium of the convoluted tubules.

the peritoneal cavity, or of general sepsis. I found colon bacilli in the kidney cortex of two dogs (iv P. and 1072 P.), which died within two days after the operation, and in such enormous numbers that the convoluted tubules were packed with them.

Sections showed severe hyperæmia, marked leucocytic infiltration, and some parenchymatous change. Cultures from the blood and various organs showed a rich growth of *Bacterium coli commune*. Mortality, 84 per cent.

Four dogs died between the second and tenth days (P. 805 and 940, P. ii and P. ix), of pyelonephritis and general sepsis.

Dog "A."—Implantation of the left ureter into the rectum. The dog lived eight days (xiii P.). Pyelitis and pyelonephritis of the side operated on. Fibrinous thrombi in both ventricles of the heart, extending into the pulmonary artery and aorta. Colon bacilli in both kidneys and in the blood.

Dog "B" lived nine days (ix P.). Pyelitis and pyelo-

nephritis. Extensive medullary changes, necrotic black papillæ.

Histopathology: Many small cortical abscesses with colon bacilli. Necrotic papillæ and colon bacilli in the collecting tubules, surrounded by a necrotic area, much leucocytic infiltration, with many polymorphonuclear leucocytes and red blood corpuscles in the interstitial tissue.

Three died on the tenth day, of pyelonephritis and general septicæmia (5 and 6 M., iii P.). Pyelitis, pyelonephritis, fibrinous thrombi in the ventricles of the heart; septic spleen. Colon bacilli in the kidney cortex, blood, and spleen.

One died on the thirtieth day, of pyelitis, pyelonephritis (interstitial small-cell infiltration, dilated uriferous tubules, capsules partly denuded of epithelium). Thrombosis of the portal vein. Colon bacilli in the kidney cortex and pelvis.

One died thirty-nine days after the operation (iv P., 1128), of pyelonephrosis and pyæmia. Endocarditis, septic spleen and liver.

Two dogs were killed forty days after the operation (P. i and ii, 1012 and 1032). One (P. i) had small granular atrophic kidneys with distinct evidence of former pyelonephritis. The colon bacilli had been destroyed with the tissue necrosis and cicatrization. The cultures showed no growth.

Histopathology: Proliferation of interstitial connective tissue, forming dense rays from papillæ to cor-

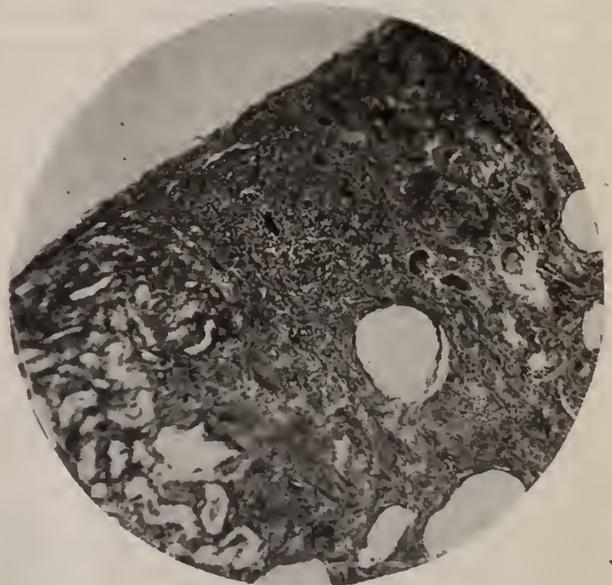

FIG. 10.—Implantation of both ureters into the rectum. The dog was killed ninety days after the operation. Atrophic granular kidney. Much interstitial hyperplasia with contraction and small-cell infiltration. Dilated, desquamated tubules and atrophic glomeruli, with thickened capsules.

tex, with retraction on the surface of the cortex. Many dilated desquamated tubules. Vessel walls thickened. Some cloudy swelling.

The other dog (P. ii) showed pyelitis and pyelonephritis, pyo-ureter, and fibrinous thrombi in both ven-

tricles, extending into the aorta and the pulmonary artery. Pyæmia. Cultures show rich growth of colon bacilli from both kidneys, the spleen, the liver, and the blood.

Histopathology: Pyelonephritis.

Macroscopical specimens "C" demonstrated:

One dog died sixty days after the operation (dog 5, P.), from pyelonephritis and pyæmia of one kidney and

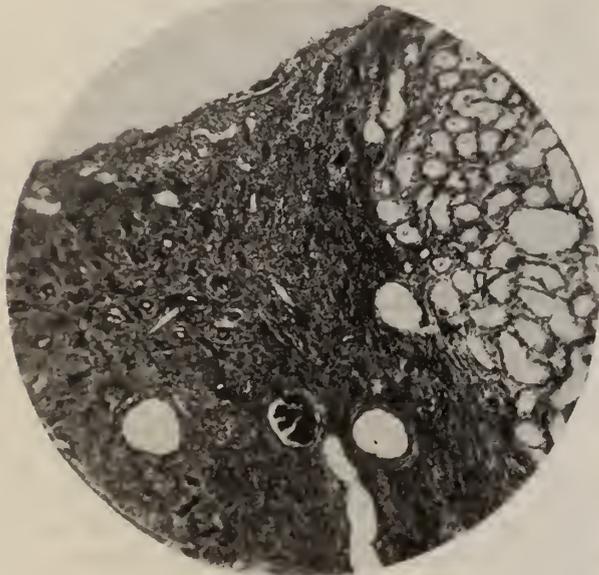

FIG. 11.—See Fig. 10.

parenchymatous nephritis of the other kidney. The right kidney was granular, with millet-seed cortical abscesses containing colon bacilli. Adherent capsule, old and recent pyelonephritis. The left kidney was enlarged and pale, and the capsule stripped off easily. No bacteria were found in smears or culture. Thrombosis of the portal vein, colon bacillus, and staphylococcus infection of the liver. Fibrinous thrombi in the right auricle and ventricle, with *Staphylococcus albus*. Purulent cystitis.

Histopathology: Right Kidney.—Pyelonephritis and granular atrophy. Hyperplastic interstitial connective tissue in the form of rays from papillæ to cortex, with cicatricial retraction of the surface of the cortex. Dilated tubules, with desquamated epithelium and granular detritus. Vessel walls thickened. Some cloudy swelling and necrosis.

Left Kidney.—Parenchymatous nephritis, cloudy swelling, fatty degeneration, and necrosis of epithelium of the convoluted tubules. Very little interstitial change.

Two dogs died eighty-four and eighty-seven days after the operation (dogs 3 and 8, P.). The first (eighty-four days) died of pyelonephrosis and pyæmia (mixed infection), pyelonephrosis, and pyo-ureter on the right side. *Bacillus coli communis* and *Staphylococcus albus*. Pyelonephritis of the left kidney. Fibrinous thrombi in the heart. Septic spleen and liver, with colon bacilli. Purulent cystitis with *Staphylococcus albus*.

The second dog (eighty-seven days) died of pyelonephritis and pyæmia (mixed infection). Slightly granular kidney, with adherent capsule and pyelonephritis. Pyo-ureter. Septic endocarditis with fibrinous thrombi. *Staphylococcus albus* and colon bacilli in the spleen, liver, and heart. Colon bacilli in the ureter and kidney.

One dog was killed ninety days after the operation (M., 4). Cultures taken from the live organs (chloroform narcosis).

Right Kidney.—Macroscopic specimen "D" demonstrated: Recent pyelonephritis, with colon bacilli. Non-adherent capsule. Millet-seed abscesses over the whole surface of the kidney, purulent rays from papillæ to cortex.

Left Kidney.—Old pyelonephritis, with granular atrophy of the middle of the convex border and adherent capsule. No bacteria.

Purulent cystitis with *Staphylococcus aureus* and colon bacilli, septic spleen and liver (*Staphylococcus aureus* and colon bacilli). Ureters comparatively healthy.

Histopathology: Atrophic granular kidney. Much interstitial hyperplasia with contraction and small-cell infiltration. Dilated, desquamated tubules and atrophic glomeruli with thickened capsules.

One dog died 127 days after the operation (M., 1), of pyelonephritis and pyæmia. Pyelonephritis and pyelitis of both kidneys, colon bacilli in both kidneys (uriniferous tubules) and ureters. Thrombosis of the por-

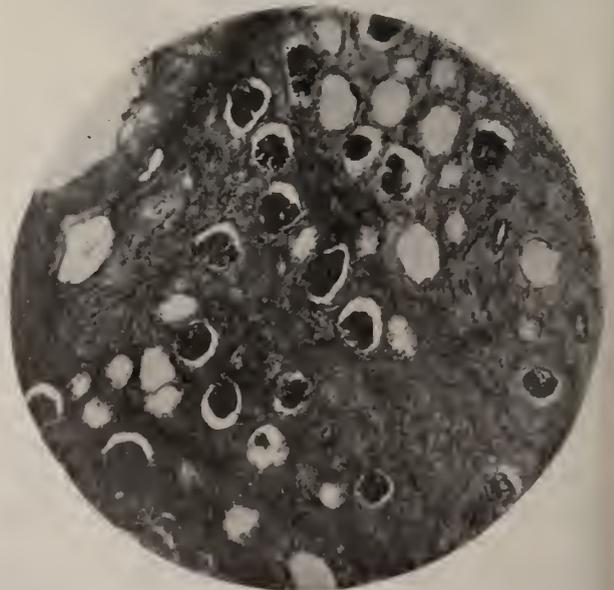

FIG. 12.—Ureteral implantation of both ureters into the rectum. The dog died three hundred days after the operation. Extensive induration and cicatrization. The newly formed and indurated fibrous tissue contains only a few atrophic glomeruli. Here and there small-cell infiltration is present in this section.

tal vein. Septic spleen. Cystitis. The bladder contained purulent fluid with colon bacilli and *Staphylococcus albus*. Fibrinous thrombi in the heart. Leg

œdematous, with purulent exudate in the subcutaneous tissues and colon bacilli.

One dog was killed 210 days after the operation (M., 7). Macroscopic specimens "E" demonstrated: Old pyelonephritis with granular atrophy. Hydronephrosis of both kidneys and hydro-ureter. No growth of bacteria in cultures. Purulent cystitis with colon bacilli and *Staphylococcus albus*.

One dog died 300 days after the operation (3, M. 851) with small granular atrophic kidney, the result of old pyelonephritis. No bacteria found.

Histopathology: Extensive induration and cicatrization. The newly formed and indurated fibrous tissue only contained a few atrophic glomeruli; here and there

small cortical abscesses of pyelonephritis seen in other cases had resulted here in infarct-like retractions by scar tissue.

IMPLANTATION OF THE TRIGONUM INTO THE RECTUM.—Peterson operated on twenty-one dogs, of which number, sixteen died during the first few days (76 per cent.), of peritonitis and general sepsis. He thinks that twelve deaths were clearly due to faulty technique.

One dog died eight days after the operation, from pyelonephritis and pyæmia. The left half of the trigonum with denuded mucosa, the right half with mucosa intact, were implanted into the rectum. Pyelitis and pyelonephritis of the left kidney. Hyperæmic right kid-

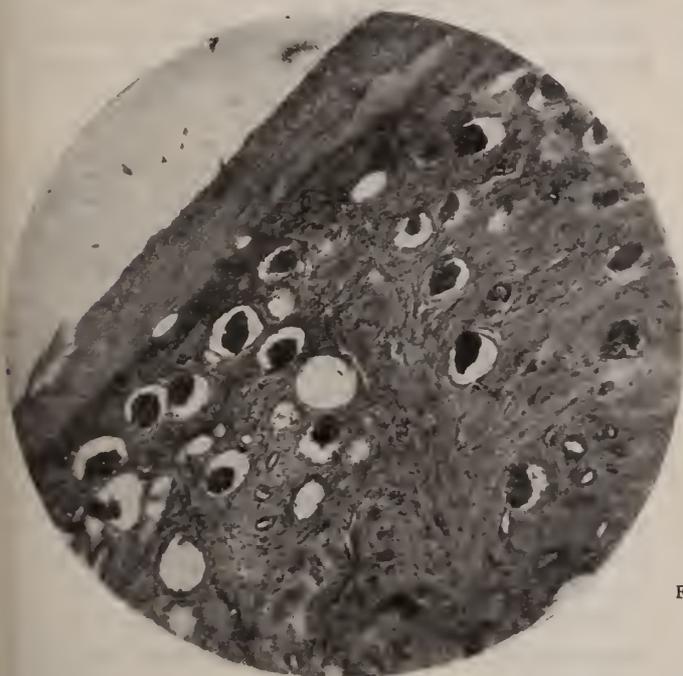

FIG. 13.—See Fig. 12.

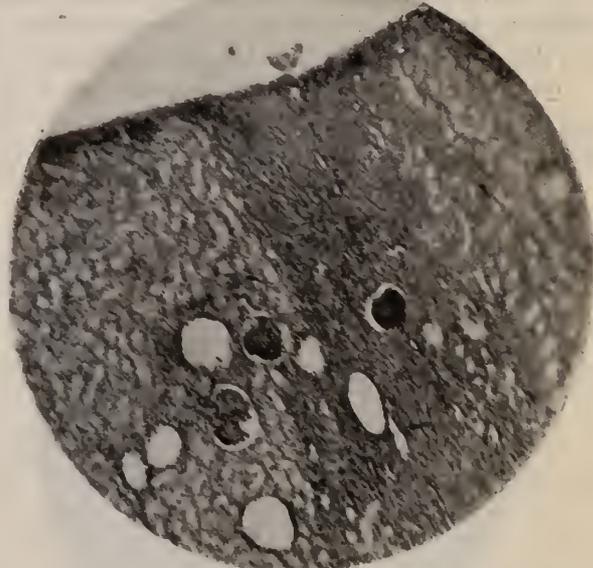

FIG. 14.—Implantation of both ureters into the rectum. Dog killed four hundred and five days after the operation. The elevated portions of the cortex consist of fairly normal parenchyma. Some cloudy swelling is present. The retracted areas consist of newly formed cicatrized connective tissue, with atrophic glomeruli, dilated capsules and leucocytic infiltration of newly formed connective tissue.

small-cell infiltration was present in this scar tissue. Mortality, 96 per cent.

One dog was killed 405 days after the operation (P., 10). Macroscopic specimens "F" demonstrated: This dog had perfectly recovered from the operation and was, to all appearances, in the very best of health when we killed him. Cultures and smears from all the organs showed no bacteria present. Both kidneys had opaque adherent capsules, with deeply branching cicatricial retractions of the surface, having macroscopically the appearance of arteriosclerotic contracted kidneys. Both ureters were dilated. Sections of the kidneys showed distinct evidence of an old pyelonephritis. Radiating, yellow, ray-like lines from papillæ to cortex surface.

Histopathology: The elevated portions of the cortex consisted of fairly normal parenchyma. Some cloudy swelling was present. The retracted areas consisted of newly formed cicatrized connective tissue with atrophic glomeruli, dilated capsules, and leucocytic infiltration of newly formed connective tissue. The many

ney, otherwise normal. Fibrinous thrombi in the heart. Abdominal wound sloughing, and pelvic abscess. Colon bacilli in both kidneys, the spleen, and the heart.

One dog was killed thirteen days after the operation. Macroscopic specimen "G" demonstrated: The dog was much emaciated and dying from pyelonephritis. The right ureter was implanted into rectum by the former method. The left ureter with the trigonum was implanted into the rectum. The results are highly interesting. The right kidney showed a well-marked pyelonephritis with pyelitis, necrotic papillæ, and opaque capsule. The cortex was covered with yellow, purulent, millet-seed abscesses, surrounded by hyperæmic zones. Yellow and red flame-like rays from papillæ to cortex. Colon bacilli in smears and cultures. Left kidney, normal. No bacteria.

Histopathology: Fully developed pyelonephritis of the right kidney. Many small abscesses in the cortex. The leucocytic infiltration was so extensive that very little of the kidney structure could be seen. Hæmor-

rhagic extravasation and polymorphonuclear leucocytes in the lumen of the tubules and in the interstitial tissue. Colon bacilli in the collecting tubules. Necrotic papillæ.

Left Kidney.—Hyperæmie, with some cloudy swelling of the lining epithelium of the convoluted tubules. No bacteria.

One dog was so sick on the forty-fourth day that we killed him. Macroscopic specimen "H" demonstrated: Pyelonephritis and pyæmia. The trigonum with both ureters was implanted into the rectum. Too much ureteral mucosa was removed, implanting flaps transversely across the bowel. Both kidneys showed advanced pyelitis and pyelonephritis and adherent capsules. Pyoureter of the right side. Colon bacilli in both kidneys. Fibrinous thrombi in both ventricles and auricles. Result the same as in uretero-intestinal anastomosis.

One dog was killed on the fifty-ninth day after the operation. Macroscopic specimen demonstrated: Trigonum implanted into the rectum. Ureters slightly di-

FIG. 15.—Pyelonephritis thirteen days after implantation of the ureters into the rectum. Many small abscesses in the cortex; the leucocytic infiltration is so extensive that very little of the kidney structure can be seen. Hæmorrhagic extravasation and polymorphonuclear leucocytes in the lumen of tubules and interstitial tissues. Colon bacilli in the collecting tubules. Necrotic papillæ.

lated. No pyelonephritis. Capsule stripped off easily. Smears and cultures negative.

Histopathology: Parenchymatous nephritis.

One dog was killed sixty-five days after the operation. Macroscopic specimen "K" demonstrated: The left ureter with half of the trigonum implanted into the rectum. This dog was in perfect health, apparently, when killed. Very small, atrophic left kidney. Capsule adherent and surface slightly nodular. Left ureter much dilated and non-patent. No bacteria in smears and cultures. Compensatory hypertrophy of the right kidney. Purulent cystitis.

ANIMAL EXPERIMENTS WITH BACILLUS COLI COMMUNIS.—It has been shown by the preceding reports that an ascending infection by the *Bacillus coli communis* takes place in every case of uretero-intestinal anastomosis, which led me to undertake some experi-

ments with a view to producing an artificial immunity against infection by these organisms. The animals experimented upon were white rats and guinea-pigs.

Virulence of Bacteria.—The virulence of the colon bacillus varies much, according to the different sources from which it is obtained. But even from the same source we cultivated bacteria which were identical in morphological and cultural characteristics, and yet varied greatly in their virulence.

The name of this bacillus stands for a whole group of bacteria. In order to determine the virulence and lethal dose of *Bacillus coli communis* to be used for immunization, I employed pure cultures obtained from two sources, of which I shall only give the most characteristic. In all cases, twenty-four-hour bouillon cultures were used (second generation), which were inoculated from discrete colonies on agar plates (first generation).

A, 1.—Second generation, from a case of colitis membranacea of Dr. Emil Ries.

(a) *Guinea-pigs.*—Intraperitoneal injection of 2 cubic centimetres killed a guinea-pig of 500 grammes in eighteen hours. Smallest lethal dose, 0.2 cubic centimetre. At the autopsy a hæmorrhagic exudate was found in the peritoneal cavity, with colon bacilli and great distention of the large intestine. Colon bacilli in the heart-blood, the spleen, and the liver.

(b) *White Rats.*—Intraperitoneal injection of 2 cubic centimetres killed a white rat of 180 grammes in from twelve to eighteen hours. Autopsy: Great distention of the colon. Hæmorrhagic exudate into the peritoneal cavity. Colon bacilli in the exudate, the heart-blood, the spleen, and the liver. Smallest lethal dose, 0.4 cubic centimetre.

A, 2.—Second generation, from a case of colitis membranacea of Dr. Emil Ries. Intraperitoneal injection of 2 cubic centimetres. Guinea-pig weighing 380 grammes:

	Degrees.	Grammes.
2d day: Temperature,	101.;	weight, 370
3d "	" 101.6;	" 320
4th "	" 102.;	" 310
5th "	" 102.;	" 285
6th "	" 101.4;	" 295
7th "	" 101.;	" 315
8th "	" 101.;	" 333
12th "	" 100.2;	" 360

B, 1.—Second generation, from the rectum of a healthy guinea-pig of 370 grammes. The same guinea-pig, inoculated with 2 cubic centimetres, showed loss of weight and lowered temperature for several days, but recovered completely within ten days, at which time its weight was the same as before inoculation.

B, 2.—Second generation, from the rectum of a healthy guinea-pig. One cubic centimetre killed a guinea-pig of 350 grammes in from twelve to eighteen hours.

It is evident from this that, of the four cultures used, only two (A, 1 and B, 2) were virulent, although no cultural or morphological difference could be made out between virulent and non-virulent cultures.

Immunity.—Löffler and Abel (46) have already shown that the poisonous principle of the colon bacillus is in the bacterial bodies and cannot be separated, so we used for our experiments:

1. Living cultures of virulent colon bacilli, one tenth of lethal dose, by subcutaneous injection.

2. Cultures killed by heat.

A white rat of 177 grammes was injected subcutaneously with 0.04 cubic centimetre of living culture A, 1.

	Degrees.	Grammes.
1st day: Temperature,	101.;	weight, 170
2d " "	101.;	" 160
3d " "	101.;	" 155
4th " "	100.;	" 160
5th " "	99.;	" 161
6th " "	99.;	" 171
8th " "	99.;	" 172
10th " "	99.;	" 180

On the twelfth day another subcutaneous injection of 0.08 cubic centimetre was made, without fever reaction or loss of weight.

On the 14th day, 0.1

On the 19th day, 0.2

On the 24th day, 0.4 (Lethal dose.)

On the 30th day, 1.0

A large necrotic area with hard, swollen base and circumference had formed on the abdomen where the injections had been made. This animal now received an intraperitoneal injection of 1 cubic centimetre of his virulent culture—that is, more than double the lethal dose—but without effect. A serum test showed marked and immediate clumping of bacilli in a dilution of one drop of blood with fifty drops of bouillon culture.

When we tried the same reaction with other colon cultures, it proved negative. The animal then received an intraperitoneal injection of 2 cubic centimetres of the virulent bouillon culture B, 2, and died the same night. The autopsy showed hæmorrhagic exudate with colon bacilli in the peritoneal cavity and in the heart-blood and the spleen. It appears from this that the animal was immune only to *Bacterium coli*, A, 1.

The same experiment was done on several guinea-pigs with practically the same results. We now used dead cultures (killed by heat) of the same *Bacterium coli*, A, 1, in a third generation for immunization of another guinea-pig, and found again a positive serum reaction after we bled the animal to death to obtain the serum. This serum clumped only the same colon bacilli which were used to produce the immunity.

The experiments are not concluded, and will be the

subject of a future paper; but it would seem from the results obtained so far that artificial immunity to the group of bacilli constituting the so-called colon group, to prevent ascending infection in cases of ureteral implantation into the rectum, is impossible, although it is the only hope of making such an operation feasible.

Implantation of the trigonum into the rectum (Maydl's operation) cannot be done in cases of malignant disease of the bladder. The same may be said of vesicorectal anastomosis (Frank).

These operations are very efficient in the prevention of early ascending infection, but, of course, out of the question where the trigonum is diseased and the bladder must be removed.

Renal infection does not take place until very late, when the normal ureteral vesical orifices become deficient and an ascending infection or pyelonephritis may follow

FIG. 16.—See Fig. 15.

in the same manner in which it occurs in an old purulent cystitis. For a time the normal vesical orifices resist the entrance of bacteria, until a purulent cystitis encroaches also upon the region of these valve-like structures, and then pyelonephritis results. Artificial immunity would seem here, also, the only resource.

CONCLUSIONS.

1. Ureteral implantation into the rectum is always followed by ascending infection. The resulting pyelonephritis is caused by the *Bacillus coli communis*.

2. The primary mortality is very large, 84 per cent., no matter which operation is done.

3. Of 120 dogs operated upon, 90 per cent. died of peritonitis due to leakage of urine or general sepsis and pyelonephritis during the first ten days.

4. Dogs living a longer time died of pyelonephritis, pyelonephrosis, and pyæmia.

5. Dogs which had fully recovered from the operation and the resulting pyelonephritis, and were, to all appearances, in perfect health and vigor again, all had granular contracted kidneys, due to induration and cicatrization of diseased areas. The rectum acts as a fair substitute for the bladder in such cases.

6. Dogs which had fully recovered after unilateral implantation were living by the other kidney. The kidney of the side operated on was atrophic and granular, the result of an early pyelonephritis. The functionally active kidney was of two to eight times the size of the atrophic one.

7. A review of the literature on uretero-intestinal anastomosis in man shows that no better results can be expected in man than in animal experiments.

8. The ureters are frequently dilated, but show very little or no disease, no matter how extensive a pyelitis or pyelonephritis is present.

9. The bladder is always infected by way of the urethra, whether it is emptied at the time of operation or not. A purulent cystitis was found in every case, caused by *Staphylococcus albus* and *Bacillus coli communis*.

10. Artificial immunity to infection by the so-called colon group of bacteria is the only hope of making uretero-intestinal anastomosis a feasible operation.

AIR, A FACTOR IN DIGESTION.

By EDWIN W. MOORE, M. D.,

FRANKLIN, PA.

As students of anatomy and physiology, we have been taught that the organs of digestion start at the mouth and end at the ileocæcal valve; that the functional possibilities are completed at this point, and the resulting product is ready for absorption and assimilation. This, I take it, is complete so far as it goes; but if put to the test, it is only a part of a truth—that completed digestion implies a further catalytic change which is furnished in the lungs.

In this presentment I do not purpose entering the domain of the experimental physiologist, but will simply follow the trend of established anatomical and physiological fact. It is not necessary to follow the food elements through mastication and through the results of the action of the varied ferments from the mouth to and through the small intestines, for these changes are accepted; neither is it necessary to follow the water and the salines in their ready absorption into the venous circulation; but it is necessary to follow the resulting absorption of the food elements from the intestines. Here we find two factors at work—the venous and the lacteal

systems. It is immaterial which has the greater prominence, so far as our proposition is concerned, because this introduces the point at issue—viz., if the digestive processes are completed at the ileocæcal valve, why the anatomical arrangements for a further physiological act?

It is a recognized fact that the lacteal system collects the results of digestion and empties them into the receptaculum chyli. At this point is added to it the result of the lymphatic absorption—a venous auxiliary in the collection of the lymph or used-up material from the body. The conjoined fluid is carried by the thoracic duct to the left subclavian vein, with a usual conduit to the right subclavian vein. At these points the elements of the food are added to the venous blood returned from the upper part of the body, after the elements of nutrition have been abstracted. Surely no one can conceive of a completed process by the commingling of a fluid practically void of the life elements with a fluid bearing the elements of life minus one factor—oxygen. The pulmonic circulation, which has to do with the return, or venous, circulation, plus the food elements of digestion, to this point, empties the combined fluid into the right auricle; from this it passes into the right ventricle, and from this through the pulmonary arteries to the lungs. Here, the last, and possibly the most potent, part of digestion takes place, the elimination of carbonic acid, etc., and the oxygenation of the venous blood, plus the new products from the food. After the oxygenation—a unique process—the completed, reanimated, fully digested product is sent to the left auricle through the pulmonary veins, bearing all the elements of nutrition and in a condition for assimilation. It then passes into the left ventricle and is sent from thence on its errand to foster the life and growth of all parts of the body through the systemic circulation.

The anatomy and physiology of the circulation of the blood in the heart demonstrate the necessity of this last act in digestion. The blood to foster the growth and maintenance of this organ is furnished by the systemic circulation through the coronary arteries. After it has abstracted the elements for its growth and sustenance the veins collect the residue and return it to the right auricle, whence it issues again to commingle with the venous blood and the food products furnished by the pulmonic circulation.

It follows as a rational sequence that the last act in digestion is accomplished in the pulmonic circulation in the lungs, and that oxygen is the necessary chemical element: that oxygenation is a part of the digestive process because, from the time food has entered the mouth, the circuit has not been changed, barring the absorption of water and the salines, until the systemic circulation has become a factor; that the pulmonic circulation affords the first time at which oxygen is added to the sum of the elements; that all oxygen furnished to the system prior to this is abstracted from, not added to, the sum of the elements after ingestion; that there is a lung digestion

as surely as a stomachic or intestinal, and that its place and importance will appear clear on analysis.

This statement abridges the function of the systemic circulation and increases the function of the pulmonic circulation. The one ceases at the arterial capillaries, the other begins at the venous capillaries. The veins and lymphatics are carriers of dead blood and lymph, deoxygenated blood and lymph, or at least blood and lymph deprived of life-begetting elements plus the food elements gathered up by the lacteals and veins, and this product must be oxygenated before it can impart its vital elements to the body.

THE PROPER ADMINISTRATION OF THE SCHOTT EXERCISES.

By VICTOR NEESEN, M. D.,

NEW YORK.

SINCE the appearance of my article on the Schott treatment of chronic heart disease in the *New York Medical Journal*, about a year ago, I have received numerous requests to further elucidate the manner in which the exercises should be given. But realizing that it is well-nigh impossible to acquire the art of administering the exercises from a mere perusal of written directions, and knowing, as I do, the harmful effects that can result from an improper use of the remedy, I have refrained from any endeavor to teach through the medium of the press and have confined my labors of tuition to those who have come to me for personal instruction.

Of late, however, I have run across several cases that have fared badly as a consequence of the improper administration of the exercises. This I know because, after the operator was corrected and the exercises were given properly, the patient improved. In some of these cases the operator employed was not at all skilled, he being the valet or butler; in others, regular Swedish masseurs or masseuses were in attendance, but upon inquiry it was found that their knowledge of the Schott exercises had been gained from a perusal of some book or monograph on the subject, or perhaps at second hand through the instruction of the doctor who had himself gained his knowledge from the books or medical journals.

The chief and most frequent error I found to be too strong a resistance. The patients were, in part, responsible for this mistake. When a light resistance was given, they pooh-poohed it, thought it child's play, etc. Some people (and especially self-made men) want the fullest value for their money, and they think that twice as much resistance is going to do them twice as much good.

Another error was rapidity. The patient, as well as the operator, seemed to want to get it over as soon as possible. Frequently, there was no sitting-down rest between each movement. The operator wanted to get to

his other patients and the patient wanted to get to his business or his pleasure. Each was in a hurry.

In some cases I found the patient without a particle of enthusiasm, taking the exercises as he would a nasty dose of drugs. A frequent remark was "I don't question my doctor's judgment any more than my lawyer's, but I don't see what good these movements are going to do me."

Another somewhat frequent fault was "holding the breath" during a movement. Either the degree of resistance was so strong that it required great effort on the part of the patient to overcome it, and holding the breath was a natural consequence; or the patient simply forgot to breathe. The former was secondary to the fault of over-resistance. The latter was due to a habit of mind concentration, and should have been combated by eternal vigilance on the part of the operator.

I have therefore come to the conclusion that it would do no harm, and indeed might prevent harm, if some directions were given and the danger signals pointed out.

When an operator comes to me to be taught, I first instruct him how to count the pulse. In every case he should count the pulse and note it before, during, and after the *séance*. The pulse is the best indication of the good or bad effect of the exercises. When the effect is good, the pulse will go down, or, at least, not go up (except in bradycardia); and if the pulse goes up, there is a fault somewhere which must be corrected.

There are two ways to count a pulse: Counting the rhythm and counting the beat. In a markedly intermittent pulse, if the beat alone is counted a very erroneous

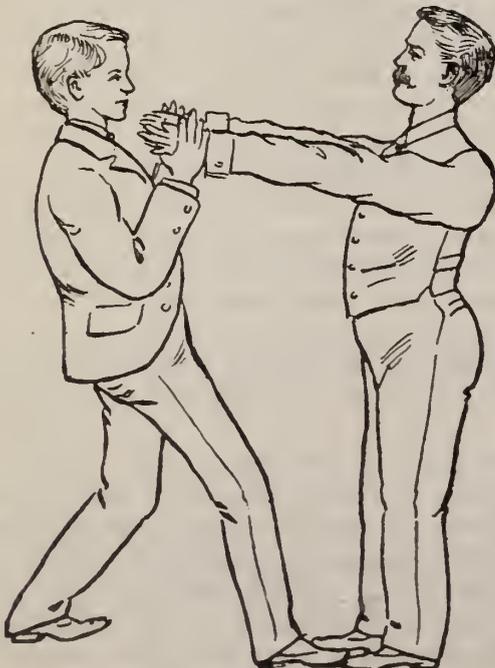

FIG. 1.—Beginning the first movement.

impression of the pulse rate may be obtained. There may be only fifty beats to the minute and yet the heart's action may be very rapid indeed. The way to count the

rhythm is to count right along, following the rate of the beat, and filling in the interval with imaginary beats. Thus, a heart having actual beats numbering sixty may

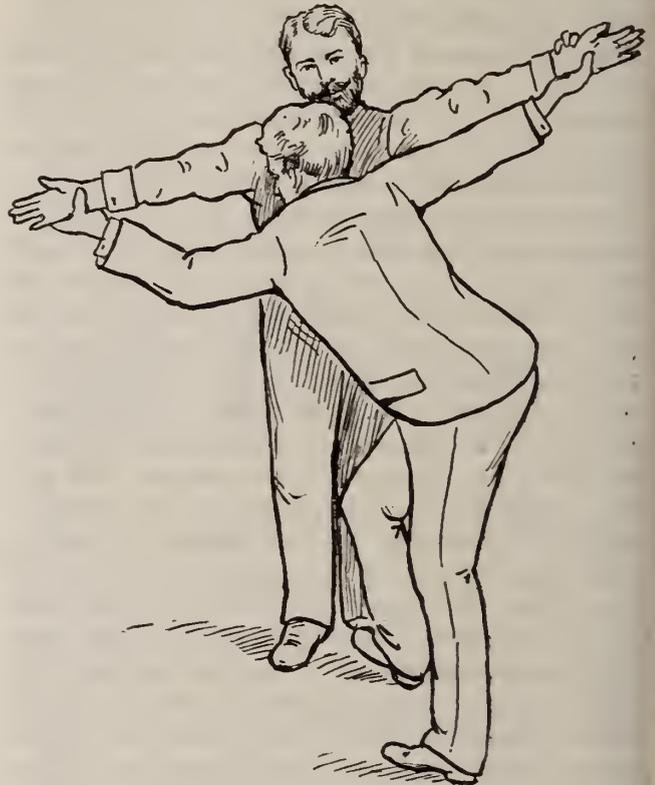

FIG. 2.—Second half of first movement.

have a rhythm of ninety. This is important because the exercises will bring the rate down from ninety and up from sixty.

I next explain to the operator the object of the movements. In the words of Schott, "Movements without design weaken the heart; movements with design strengthen the heart." The primary object of the exercises is, *not* to develop the muscles, but (a) to relieve the overburdened heart by (1) drawing the blood away from it into the extremities and muscular structures; (2) accelerating the circulation (contraction of the muscles upon the blood-vessels); and (3) soothing the nervous mechanism of the heart by acting upon the motor nerves through the slow movements of the muscles; and (b) to strengthen the heart muscle.

I then rehearse the *rules*:

1. Each movement is to be performed slowly and evenly, without jerking or trembling.

2. Each movement is to be followed by an interval of rest (sitting).

3. Arm movements should alternate with leg or body movements.

4. No part of the body is to be held so as to compress the blood-vessels or interfere with the breathing.

5. The patient should be instructed to breathe naturally and regularly.

6. The patient should be watched closely for (a)

irregular breathing, (b) straining, (c) trembling, (d) flushing or pallor of face and lips, (e) dilatation of nostrils, (f) yawning, and (g) drawing down of the corners of the mouth.

FIG. 3.—Second movement.

If any of these signs are exhibited, something is at fault—usually too much resistance or too rapid execution.

The *movements* are as follows:

No. 1.—Both arms are moved simultaneously from the extended horizontal position in front to the extended

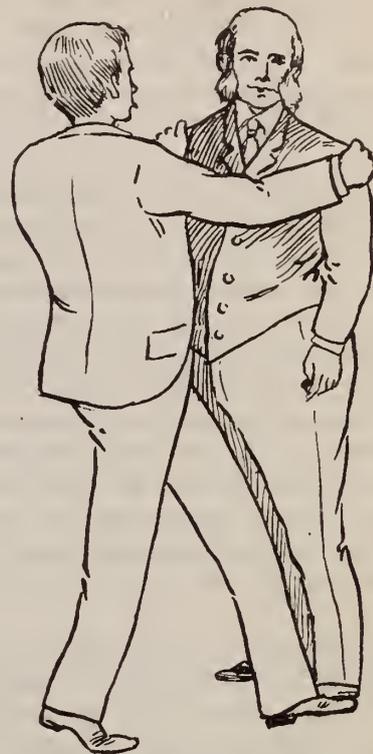

FIG. 4.—Sixth movement.

horizontal position at the sides and returned to the first position. The operator's four fingers compose the resisting surface during the first half, and the thumbs during the second. One foot should be extended close to the patient to maintain the balance.

No. 2.—The patient rests one hand on the back of a chair and raises the inside knee as high as he can and returns to first position. The operator disposes himself on the right knee, places his right hand on the arch of the foot for the first half, and under the instep for the second.

No. 3.—The patient raises the arms from the hang-

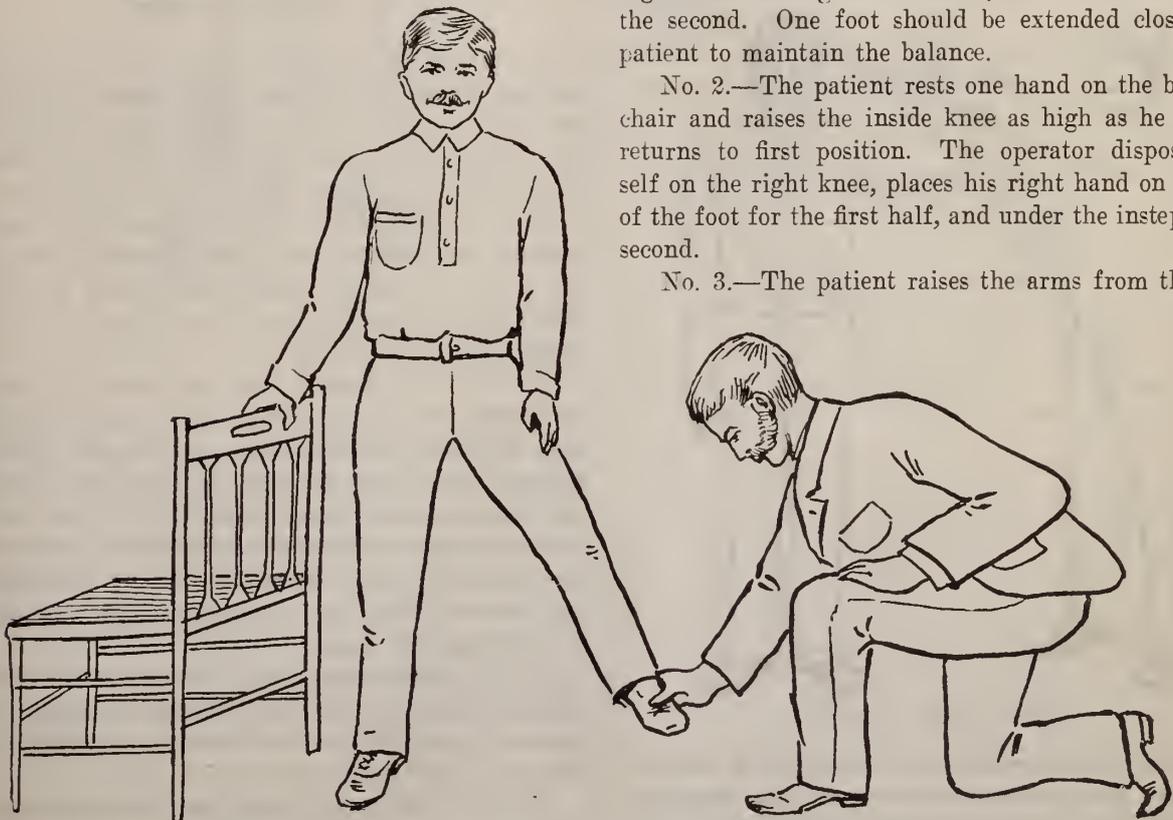

FIG. 5.—Ninth movement.

ing position to the side-horizontal position and return. The operator's four fingers resist the downward as well as the upward movement.

No. 4.—The patient rests a hand on the back of a chair and raises first one foot, then the other behind him, flexing the knee. The operator resists with the fork of his thumb and finger behind the heel for the upward, and with the fingers in front of the ankle for the downward, movement.

No. 5.—The patient's arms are raised from the hanging position to the front-horizontal position and return. The operator resists with the fork of his hand at first, but as the arms rise he twists his hands so that the fingers are resisting at the finish. In the return movement the operator's fingers are curved under the patient's wrists.

No. 6.—The patient twists the upper portion of his body first to one side, then to the other side, and return. The feet are kept still and the hands hang at the sides. The operator's left hand resists the right shoulder, and the right hand is placed behind the left shoulder over the scapula—that is, when the patient twists to the left; the hands are changed when the twist to the right is begun.

No. 7.—Resting one hand on the back of a chair, the patient raises one foot in front of him, returns it, and does the same with the other. The operator resists with the fork of his thumb and finger in front of the ankle, and then with his four fingers behind the ankle.

No. 8.—The patient flexes the forearm on the arm in the hanging position and return. The operator places one hand on the patient's shoulder and resists with the

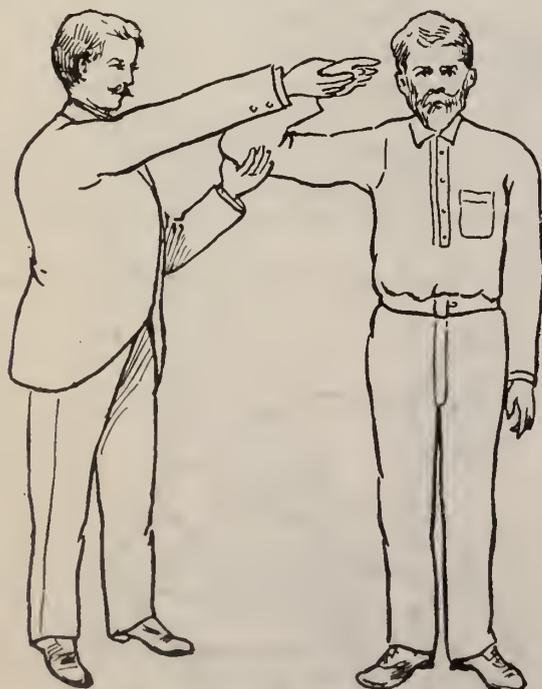

FIG. 6.—Tenth movement.

other hand over the wrist. The hand should not rest heavily on the shoulder, however, and the resistance should be kept up until the fingers touch the shoulder.

No. 9.—The patient rests one hand on the back of a chair and raises one leg sideways as far as he can. The operator squats or kneels, and resists with the fork of his right hand, the resistance diminishing as the leg rises.

FIG. 7.—Twelfth movement.

No. 10.—With the patient's arm extended in the side-horizontal position, he flexes the forearm on the arm. The operator places his left hand under the patient's elbow and resists with the four fingers of the right hand curled around the patient's wrist.

No. 11.—The patient sits in a chair without arms and separates the knees as far as possible without displacing the feet. The operator squats before him and resists with his four fingers outside of the knees, and, on the return, inside of the knees.

No. 12.—The patient starts one arm at a time forward from the hanging position, then upward, then backward, then downward, making a complete circle in the air with his hand. This is called the windmill movement. One of the operator's hands is laid lightly upon the patient's shoulder and resistance is made with the four fingers of the other until the arm reaches the overhead vertical position, when the hands must be quickly changed for the downward sweep.

No. 13.—The patient sits on the edge of a chair and raises one foot at a time until the leg is straight. Resistance is made with the fork of the hand in front of the ankle and with the fingers behind the ankle.

No. 14.—The patient bends the body forward at the hips, the arms remaining hanging at the sides. The op-

erator stands at the patient's side, places his left hand in the small of the patient's back, his right hand in front of the left shoulder, and his own right shoulder in front of the patient's left shoulder. He resists with his body, bending his right knee as the patient bends his body. The upward movement is resisted by the operator's left hand placed between the shoulder blades, his right hand being placed over the pit of the stomach, as a sort of counterbalance.

These, then, are the principal exercises as they are given in Bad Nauheim by Professor Schott's masseurs. Of course, it is manifestly impossible to give any directions concerning the amount of resistance to be employed. Each case must have its own adaptation.

As to the contraindications, they are few. Advanced

FIG. 8.—Fourteenth movement.

atheroma, aneurysm, and acute inflammatory carditis comprise the list.

But in a great many cases the patient himself will decide that the exercises are not exactly suited to his case, and he will come to this conclusion for this reason: After a very short trial he will not see the miraculous improvement in his condition that he expected, and, as the treatment is rather expensive, he will go back to his drugs.

In closing, I might say that the use of mechanical appliances to take the place of the operator is not sanctioned by Professor Schott; in fact, he is opposed to them on the ground that they are not at all satisfactory and are in some cases harmful.

335 WEST FIFTY-FIRST STREET.

THE USE OF THE SUPRARENAL CAPSULE IN DISEASES OF THE HEART.

(Second Paper, with a Report of Cases.)

By SAMUEL FLOERSHEIM, M. D.,

NEW YORK.

(Concluded from page 765.)

CASE XXIX.—The patient, a girl, thirteen years old, had mitral regurgitation. The pulse was 104, slightly irregular, and of fair force. After the administration of the suprarenal capsule, the mitral murmur became softer, and decreased in volume. The pulse was 91 and regular.

Remarks.—The patient had chronic bronchitis, which was temporarily relieved.

CASE XXX.—The patient, a woman, twenty-six years old, had mitral regurgitation; the heart's action was very irregular. The pulse was 86, very irregular, and weak; there were many beats dropped. After the administration of the suprarenal capsule, the heart's action became more regular. The pulse was 84, nearly regular, and strong; nearly all the intermittence had disappeared.

Remarks.—The tightness and sensation of a foreign body in the epigastrium were relieved.

CASE XXXI.—The patient, a man, aged sixty-four years, had mitral regurgitation and aortic stenosis. The apex beat was at the sixth rib, three quarters of an inch to the left of the left nipple line. There was beginning cardiac dilatation. The pulse was 96, of fair force, and regular. After the administration of the suprarenal capsule, the mitral murmur became decreased in volume and intensity; at times it was almost inaudible. The aortic murmur became louder, plainer, and localized. The pulse was 84, increased in force, and regular.

Remarks.—The severe attacks of dizziness and staggering gait almost disappeared after one dose of the powder.

CASE XXXII.—The patient, a young man, eighteen years of age, had slight mitral regurgitation; the heart's action was irregular. The pulse was 104, irregular and weak. After the administration of the suprarenal capsule, no marked effect was produced. The heart became only slightly more regular. The pulse was 104, more regular, and slightly increased in force.

CASE XXXIII.—The patient, a man, aged fifty-four years, had myocarditis; there was slight aortic regurgitation and forcible heart-beating against the chest. The pulse was 73, and irregular in force and frequency; six beats were dropped every minute. After the administration of the suprarenal capsule, the forcible heart-beating disappeared. The pulse was 84, nearly regular, softer, and fuller. Two beats were dropped every minute.

Remarks.—The patient had an attack of rheumatism.

CASE XXXIV.—The patient, a little boy, nine years old, had mitral and aortic stenosis and regurgitation. There was marked hypertrophy with beginning dilatation. The normal cardiac sounds were inaudible; a confusion of murmurs was heard; the apex beat was diffused. The heart's action was irregular. The pulse was 100, irregular in frequency and force, trembling, and weak. After the administration of the suprarenal capsule, the heart was contracted a quarter of an inch on each side; the heart's action became stronger and more regular. The apex beat became localized and was more easily located. All the murmurs became decreased in volume and intensity, and became localized and were much more

easily distinguished. The episternal pulsation became more pronounced, and the heart was powerfully stimulated. The pulse was 100, regular in frequency, quite full, and the force became markedly increased.

Remarks.—The patient was taking other treatment without any benefit. The headache and attacks of dizziness were relieved. The patient felt much better after the ingestion of the powder.

CASE XXXV.—The patient, a man, aged thirty-five years, had mitral regurgitation. There was marked hypertrophy with beginning dilatation. The pulse was 89, of fair force, irregular in frequency, and hard. Many beats were dropped. After the administration of the suprarenal capsule, the heart's action became much easier and more regular, and the apex beat was more easily located. The pulse was 86, of good force, more regular, soft, and full. The intermittence had disappeared.

Remarks.—The patient had phthisis pulmonalis in the third stage, laryngeal tuberculosis, and left sciatica.

CASE XXXVI.—The patient, a woman, fifty-nine years of age, had mitral regurgitation, and a dilated and weak-acting heart. The pulse was 92, irregular, weak, and thready, and almost imperceptible at the wrist. A few beats were dropped. After the administration of the suprarenal capsule, the heart was markedly stimulated, the mitral murmur had almost disappeared, and the action of the heart became regular. The pulse was 90, strong, full, soft, and regular, and all the intermittence disappeared.

Remarks.—The severe attacks of headache, dizziness, and fainting spells were relieved by the drug. No other medication was given.

CASE XXXVII.—The patient, a woman, aged thirty-nine years of age, had a loud, blowing, mitral regurgitant murmur. The pulse was 82, regular, full, and strong. After the administration of the drug the heart's action was slightly increased in force. The pulse was 82, fuller, and stronger.

CASE XXXVIII.—The patient, a man, aged thirty-eight years of age, had mitral regurgitation and cor bovis. The heart's action was very irregular and very weak; the mitral murmur was diffused and blurred; the apex beat was diffused. The pulse was 50, irregular, very weak, and nearly imperceptible at the wrist. After the administration of the suprarenal capsule, the heart's action became stronger, the apex beat became localized, and the mitral murmur became circumscribed. The pulse was 61, fairly strong, full, soft, regular, and easily perceptible at the wrist.

Remarks.—The patient had convulsions, due, in all probability, to an embolus from the heart. A marked effect of the drug was produced in this case.

CASE XXXIX.—The patient, a woman, aged sixty-four years, had mitral regurgitation. The pulse was 94, irregular, and weak. After the administration of the suprarenal capsule, the heart's action became stronger. The pulse was 86, regular, strong, and soft.

Remarks.—The patient had tuberculous cystitis with hæmaturia. The latter was completely controlled by the drug.

CASE XL.—The patient, a little girl, ten months old, had mitral regurgitation. The pulse was 123, irregular, and of fair force. After the administration of the suprarenal capsule, the heart's action became stronger and easier. The pulse was 106, regular, fuller, and increased in force.

Remarks.—The cyanosis of the face and neck, and the bronchitis, were relieved by the drug.

CASE XLI.—The patient, a man, twenty-nine years

of age, had mitral regurgitation, and a weak and dilated heart. The normal heart sounds were muffled; the apex beats were very weak, and the impulse was diffused. The heart beats were 69, weak, and irregular; the radial pulse was imperceptible. After the administration of the suprarenal capsule, the heart became markedly stimulated, the normal heart sounds became more distinct, and the apex impulse became more perceptible and localized. The pulse was 73, regular, soft, and observed at the wrist.

Remarks.—The patient had phthisis pulmonalis, with attacks of dizziness, which latter were promptly relieved by the powder.

CASE XLII.—The patient, a man, forty-three years of age, had mitral regurgitation and aortic stenosis. The heart's action was weak, and the apex beat was diffused. The pulse was 102, very irregular, and weak. A few beats were dropped and many half-beats were observed. After the administration of the suprarenal capsule, the apex impulse became more easily located, the action of the heart became stronger, and the normal heart sounds became more distinct. The pulse was 89, fairly full, and nearly regular. Almost all the intermittence and the half-beats disappeared.

Remarks.—The patient had an attack of malaria and felt much relieved after the administration of the suprarenal powder.

CASE XLIII.—The patient, a woman, aged twenty-four years, had mitral regurgitation and aortic stenosis. The heart's action was very irregular, and there was heaving of the chest with each cardiac beat. The pulse was 76, very irregular, sometimes dichrotic, weak, thready, and trembling; it was almost imperceptible at the wrist. After the administration of the suprarenal capsule, the action of the heart was markedly stimulated. The pulse was 74, full, strong, more regular, and softer, and there was a fair pulse at the wrist.

Remarks.—The attacks of headache and dizziness disappeared after taking the drug.

CASE XLIV.—The patient, a man, aged twenty-nine years, had mitral regurgitation. The action of the heart was weak and irregular. The pulse was 120, irregular and weak. After the administration of the suprarenal capsule, the action of the heart became stronger. The pulse was 112, fuller, more regular, and stronger.

Remarks.—The patient had experienced the sensation of his heart beating forcibly against his chest for fifteen years, both day and night, which was very annoying. When a capsule of suprarenal extract was administered the sensation of the heart beating against the chest entirely disappeared within two minutes, and it remained absent for more than fifteen minutes, when the beating returned again, but very much diminished in force; "a light tapping," as the patient called it. This was the first time in fifteen years that the patient had been entirely relieved of this symptom. Twenty minutes later the patient felt much better and disposed to work, whereas, previous to the administration of the drug, he had felt indisposed to do anything.

CASE XLV.—The patient, a woman, forty-five years of age, had mitral and aortic regurgitation. The pulse was 104, irregular, and weak. After the administration of the suprarenal capsule, both murmurs were diminished in volume. The pulse was 88, strong, full, and regular.

Remarks.—The dizziness and general weakness disappeared after the administration of the drug.

CASE XLVI.—The patient, a woman, thirty-six years of age, had very loud aortic and mitral regurgitant mur-

murs; there was a hæmic murmur, and the heart's action was dilated and weak. The pulse was 100, irregular, weak, small, and sometimes dichrotic. Many beats were dropped and there were many half-beats. After the administration of the suprarenal capsule, the mitral murmur became almost inaudible; the aortic murmur became much lessened in volume, and the thrill at the apex entirely disappeared. The pulse was 78, nearly regular, and much stronger.

Remarks.—There was general anasarca. The urine diminished in amount and the dropsy increased steadily. Tapping was resorted to.

CASE XLVII.—The patient, a woman, forty-two years of age, had mitral regurgitation with marked hypertrophy. The pulse was 106, regular, and of fair force. After the administration of the suprarenal capsule, the mitral murmur became clearer and more localized. The pulse was 106, regular, fuller, stronger, and softer.

CASE XLVIII.—The patient, a man, aged sixty-eight years, had mitral regurgitation and a dilated heart. The heart beats were 61, very irregular, and weak; there was no radial pulse. Three or four beats were dropped. After the administration of the suprarenal capsule, the heart's action became stronger and more regular. The pulse was 69, easily felt, nearly regular, and of fair force. One or two beats were dropped every minute.

Remarks.—The patient was suffering from a malarial attack.

CASE XLIX.—The patient, a woman, forty-two years of age, had mitral stenosis and regurgitation. There was hypertrophy with beginning dilatation. The pulse was 86, weak, but regular. After the administration of the suprarenal capsule, the stenotic murmur became more easily distinguished, and there was contraction of the heart muscle. The pulse was 84, full, strong, and regular.

Remarks.—The severe dyspnoea was relieved. Drowsiness was observed a minute after the administration of the drug.

CASE L.—The patient, a man, thirty-five years of age, had mitral regurgitation and a dilated heart; the apex beat was diffused. The pulse was 66, irregular, weak, and trembling. After the administration of the suprarenal capsule, the heart's action became much stronger, and the apex beat became localized. The pulse was 79, nearly regular, full, and strong.

Remarks.—The patient had been on a ten-days' debauch. Relief was afforded.

CASE LI.—The patient, a woman, thirty-six years of age, had mitral regurgitation and hypertrophy of the heart; there was a diffused apex beat. The pulse was 69, weak, and irregular. After the administration of the suprarenal capsule, the murmur became slightly decreased in volume, and the apex beat became localized. The pulse was 76, strong, and regular.

CASE LII.—The patient, a woman, twenty-eight years of age, had mitral regurgitation and aortic stenosis; the heart was dilated and there was a diffused apex beat. The pulse was 67, irregular, and weak. There were many half-beats. After the administration of the suprarenal capsule, the mitral murmur became decreased in volume, and the apex beat became more localized. The pulse was 77, regular, and strong. The half-beats disappeared.

Remarks.—The patient felt much better after the administration of the powder.

CASE LIII.—The patient, a man, thirty-seven years of age, had mitral stenosis with hypertrophy; the apex

beat was at the sixth rib in the nipple line. The pulse was 84, weak, but regular. After the administration of the suprarenal capsule, the thrill became less marked, and the apex impulse less pronounced. The pulse was 89, regular, fairly strong, full, and soft.

Remarks.—An attack of syncope was promptly relieved by the suprarenal extract.

CASE LIV.—The patient, a woman, aged forty-six years, had mitral regurgitation and a dilated heart, with arteriosclerosis; the apex beat was diffused. The pulse was 99, very weak, irregular, trembling, and jerky. Many beats were dropped. After the administration of the suprarenal capsule the apex beat became localized, and the heart's action became stronger. The pulse was 87, nearly regular, fairly full, strong, soft, and steady. Almost all the intermittence disappeared.

Remarks.—The dizziness was much relieved.

CASE LV.—The patient, a young man, twenty-one years old, had mitral regurgitation. There was a systolic thrill at the apex and diffuse pulsation over the præcordia. The apex beat was diffused. The pulse was 51, small, and irregular. After the administration of the suprarenal capsule, the thrill at the apex disappeared, and the apex impulse became localized. The pulse was 76, regular, full, and strong.

Remarks.—Other heart tonics had failed to benefit him for four years. Under the suprarenal treatment the patient can do light outdoor work, something that he has been unable to do for the past four years.

CASE LVI.—The patient, a woman, thirty-eight years of age, had valvular cardiac disease, with beginning dilatation. Compensation had ceased. After the administration of the suprarenal capsule, the heart's action became stronger.

Remarks.—All the other heart remedies had failed to benefit her. Under the suprarenal treatment the patient was able to do light housework again.

CASE LVII.—The patient, a woman, fifty-eight years of age, had mitral regurgitation, and the heart's action was very feeble. The pulse was 120, thready, soft, and intermitting every five seconds. After the administration of the suprarenal capsule, the pulse was 120, and the volume and force were markedly increased, and intermitted only six times to the minute.

Remarks.—There were general venous stasis and anasarca. The respiration seemed to be performed with more ease, and better, after the suprarenal powder was administered.

CASE LVIII.—The patient, a woman, had mitral insufficiency. The pulse was 78 and somewhat irregular. After the administration of the suprarenal capsule, the heart was stimulated, and the pulse became stronger and regular.

Remarks.—The suprarenal powder acted well when all other treatment was discontinued.

CASE LIX.—The patient, a woman, had mitral insufficiency. The pulse was 84 and very irregular. After the administration of the suprarenal capsule, the pulse became stronger and more regular.

Remarks.—The patient did not feel any benefit from the suprarenal treatment.

CASE LX.—The patient, a little boy, five years old, had mitral regurgitation; the action of the heart was very irregular. The pulse was 132, irregular, trembling, weak, and intermittent. After the administration of the suprarenal capsule, the pulse was 101, nearly regular, and stronger.

Remarks.—The patient had rheumatism. He felt much better after taking the suprarenal powder.

CASE LXI.—The patient, a man, had mitral regurgitation, with acute and excessive dilatation of the heart. The pulse was very irregular in its frequency. After the administration of the suprarenal capsule, marked improvement in the action of the heart and of the pulse resulted.

Remarks.—When the suprarenal powder was added to the treatment marked improvement took place.

CASE LXII.—The patient, a woman, twenty-four years old, had mitral regurgitation and a dilated heart. The pulse was 96, irregular, and of fair force. After the administration of the suprarenal capsule, the mitral murmur entirely disappeared, and the heart's action became nearly regular. The pulse was 100, nearly regular, and increased in force.

Remarks.—The patient was nervous and in the fourth month of pregnancy.

CASE LXIII.—The patient, a woman, fifty-nine years of age, had mitral and aortic regurgitation; the heart's action was very irregular. The pulse was 86, irregular, intermittent, small, and weak. After the administration of the suprarenal capsule, the diastole of the heart seemed to be prolonged; the normal heart sound became louder, plainer, and more easily distinguished. The mitral murmur became much diminished in volume, the aortic murmur also became diminished in volume and more localized. The pulse was 92, nearly regular, and stronger.

Remarks.—The severe attack of bronchitis and the headaches were relieved by the powder.

CASE LXIV.—The patient, a young man, nineteen years old, had a shrill, mitral regurgitant murmur, and the heart's action was irregular. The pulse was 106, jerky, small, and irregular. A few beats were dropped. After the administration of the suprarenal capsule, the mitral murmur became less shrill and more localized, and the heart's action became stronger. The pulse was 99, nearly regular, and fairly full. One or two beats were dropped every minute.

Remarks.—The patient was suffering from malaria.

CASE LXV.—The patient, a woman, twenty-two years old, had mitral stenosis, endocarditis, and hypertrophy of the right ventricle. The pulse was 96, irregular, very weak, and thready. After the administration of the suprarenal capsule, the pulse was 79, regular, full, strong, and soft.

Remarks.—No benefit had been obtained from other treatment. When the suprarenal powder was administered improvement resulted.

CASE LXVI.—The patient, a young man, twenty-one years old, had mitral stenosis and enlargement of the right ventricle. There was a displaced apex beat and a diffused impulse along the right border of the sternum, and epigastric pulsation. The pulse was 41, and almost imperceptible at the wrist. After the administration of the suprarenal capsule, the pulse was 72, stronger, fuller, and more regular.

Remarks.—Marked improvement resulted under the suprarenal treatment. The patient had been confined to his bed, but in five days he was able to walk a mile without fatigue.

CASE LXVII.—The patient, a woman, thirty years old, had mitral regurgitation and dilatation of both ventricles. The heart beats were 55, very irregular, and weak. The pulse at times was imperceptible, dichrotic, and very weak. After the administration of the suprarenal capsule, the pulse was 73, nearly regular, full, and strong.

Remarks.—The patient had had other heart remedies

for over a year without benefit. She was cyanotic and moribund, but under the suprarenal treatment she recovered and the cyanosis disappeared.

CASE LXVIII.—The patient, a little boy, seven years old, had mitral stenosis. The pulse was 95, irregular, and very weak. After the administration of the suprarenal capsule, the pulse was 71, regular, fairly full, and strong.

Remarks.—The child had scarlatina and cardiac dropsy. He recovered under the suprarenal treatment. No other treatment was employed.

CASE LXIX.—The patient, a little girl, five years old, had mitral stenosis, with hypertrophy of the right ventricle. The pulse was 116, irregular, and weak. After the administration of the suprarenal capsule, the pulse was 93, regular, full, and strong.

Remarks.—The patient had pertussis, which was benefited by the suprarenal treatment.

CASE LXX.—The patient, a woman, twenty-one years old, had mitral regurgitation. The pulse was 123, very irregular, weak, and fluttering, and almost imperceptible at the wrist. After the administration of the suprarenal capsule, the heart became quite markedly stimulated. The pulse was 91, regular, full, and strong.

Remarks.—The attacks of syncope were prevented, and rapid improvement in the general health resulted under the suprarenal treatment.

CASE LXXI.—The patient, a woman, thirty-six years old, had aortic regurgitation and a Flint murmur. The pulse was 78, irregular in force, but regular in frequency. After the administration of the suprarenal capsule, the pulse was 76, regular in frequency, and more regular and increased in force.

CASE LXXII.—The patient, a woman, fifty-five years of age, had aortic and mitral regurgitation. The pulse was 133, and irregular in force and frequency. Four beats were dropped every minute. After the administration of the suprarenal capsule, the pulse was 126 and increased in force. One beat dropped every minute.

CASE LXXIII.—The patient, a man, thirty-eight years of age, had mitral regurgitation. The pulse was 90, and irregular in frequency and in force. After the administration of the suprarenal capsule, the pulse was 102, increased in force, and regular in frequency.

Remarks.—The patient had phthisis and rheumatism.

CASE LXXIV.—The patient, a woman, fifty-one years of age, had mitral regurgitation. The pulse was 96, regular in frequency, and of fair force. After the administration of the suprarenal capsule, the pulse was 84, increased in force, fuller, and regular.

CASE LXXV.—The patient, a woman, forty-three years of age, had a loud, blowing, mitral regurgitant murmur. Compensation was good. The pulse was 92, regular, and soft. After the administration of the suprarenal capsule, the mitral murmur became slightly lessened in intensity. The pulse was 79, stronger, and regular.

Remarks.—The acute attack of bronchitis was controlled by the suprarenal powder.

CASE LXXVI.—The patient, a young man, twenty-one years old, had mitral regurgitation. The pulse was 84, fairly strong, and slightly irregular in force and frequency. After the administration of the suprarenal capsule, the pulse was 84, nearly regular, and increased in force.

CASE LXXVII.—The patient, a man, had a doubtful aortic lesion and mitral regurgitation. The pulse was 78, regular in frequency, and irregular in force. After

the administration of the suprarenal capsule, the pulse was 78, regular in frequency, and regular and increased in force.

CASE LXXVIII.—The patient, a young man, nineteen years old, had a systolic murmur. The pulse was 96, weak, irregular in force, and regular in frequency. After the administration of the suprarenal capsule, the pulse was 90, regular in frequency, and regular and increased in force.

CASE LXXIX.—The patient, a man, thirty-six years of age, had mitral regurgitation. The pulse was 84, very irregular, and weak. After the administration of the suprarenal capsule, the pulse was 78, stronger, and more regular.

CASE LXXX.—The patient, a little boy, eleven years old, had mitral regurgitation and aortic stenosis. The pulse was 102, regular, but weak. After the administration of the suprarenal capsule, the pulse was 96, regular, stronger, and fairly full.

CASE LXXXI.—The patient, a man, thirty-eight years of age, had lesions of all the heart valves, with general arteriosclerosis. The pulse was 90, of high tension, and irregular in force and in frequency. After the administration of the suprarenal capsule, the pulse was from 72 to 80, softer, and more regular.

Remarks.—The patient had been on exhibition in New York and in other cities before classes of students in general medicine. His heart and circulatory phenomena were very interesting.

CASE LXXXII.—The patient, a woman, fifty-one years of age, had mitral and aortic stenosis, with beginning predominant dilatation. There was a diffused apex beat. The pulse was 100, very weak, and very irregular. After the administration of the suprarenal capsule, both murmurs became softer and decreased in volume, and the heart was stimulated. The pulse was 81, regular, quite full, and strong.

Remarks.—Much improvement was experienced by the patient after the ingestion of the powder.

CASES OF ORGANIC HEART DISEASE IN WHICH THE SUPRARENAL CAPSULE HAD NO APPARENT EFFECT.—EIGHTEEN IN NUMBER.

CASE I.—The patient, a woman, twenty-seven years old, had aortic stenosis. Compensation was good. The pulse was 98, regular, and fairly strong.

CASE II.—The patient, a woman, forty-nine years of age, had slight mitral regurgitation. The pulse was 69, strong and regular.

CASE III.—The patient, a man, thirty-four years of age, had slight aortic regurgitation. The pulse was 74, regular, full, and strong.

CASE IV.—The patient, a man, forty-two years of age, had slight mitral regurgitation. The pulse was 77, slightly irregular, and strong.

CASE V.—The patient, a man, sixty-eight years of age, had mitral regurgitation, with marked hypertrophy. The pulse was 86, full, regular, and strong.

CASE VI.—The patient, a woman, forty years of age, had mitral stenosis. The pulse was 79, slightly irregular, full, and strong.

CASE VII.—The patient, a man, thirty-nine years of age, had aortic regurgitation. The pulse was 69, regular, and strong.

CASE VIII.—The patient, a man, twenty-nine years old, had mitral and aortic regurgitation, with predominant hypertrophy. The pulse was 73, full, regular, and strong.

CASE IX.—The patient, a young girl, sixteen years

old, had mitral stenosis. The pulse was 87, slightly irregular, but strong.

CASE X.—The patient, a woman, forty-nine years of age, had mitral regurgitation, with predominant hypertrophy. The pulse was 91, regular, and strong.

CASE XI.—The patient, a man, thirty-eight years of age (Case LXXIII), had mitral regurgitation. The pulse was 82, regular, and strong.

CASE XII.—The patient, a woman, twenty-one years old (Case LXX), had mitral regurgitation. The pulse was 79, regular, and fairly strong.

Remarks.—When the pulse was full and strong no effect was observed, but when the pulse was irregular and weak the suprarenal capsule produced an effect.

CASE XIII.—The patient, a woman, fifty-one years of age (Case LXXIV), had mitral regurgitation. The pulse was 86, regular, and strong.

CASE XIV.—The patient, a woman, aged forty-two years, had slight mitral regurgitation. Compensation was good. The pulse was 87, slightly irregular, strong, and full.

CASE XV.—The patient had a mitral regurgitant murmur. The pulse was 80 and regular. The blood-pressure was 120. Measured by the tonometer.

CASE XVI.—The patient had an aortic regurgitant murmur. The pulse was 82 and regular. The blood-pressure was 118. Measured by the tonometer.

CASE XVII.—The patient had mitral regurgitation and aortic stenosis, and a presystolic murmur which disappeared when the patient was quiet and rested. The pulse was 80 and regular. The blood-pressure was 118. Measured by the tonometer.

CASE XVIII.—The patient, a young boy, sixteen years old, had mitral regurgitation, with slight hypertrophy. The pulse was 77, regular, full, strong, and soft.

Remarks.—The acute bronchitis was relieved by the suprarenal powder.

Conclusions.—After the administration of the suprarenal powder, the following was observed:

1. A weak and irregular-acting heart became stronger and more regular.
2. A dilated heart was contracted.
3. A diffused apex beat became localized.
4. A diffused, loud, and rough mitral regurgitant murmur became localized, smoother, and lessened in intensity, while in some cases the murmur disappeared.
5. A murmur which, owing to the extreme weakness of the heart, could scarcely be heard, became more distinct, thus aiding in the diagnosis.
6. The normal cardiac sounds, when indistinct, became clearer and more easily distinguished.
7. In some cases a rapid pulse became less rapid; in other cases a slow pulse became faster.
8. Patients who were very weak, with organic heart disease, were improved.
9. No effect was observed in organic heart disease when the pulse was strong and regular.

218 EAST FORTY-SIXTH STREET.

J. Pierpont Morgan's Gift to a French Hospital.—J. Pierpont Morgan has given 50,000 francs to the hospital at Aix-les-Bains, and the municipality has marked its appreciation of the gift by presenting to him a bouquet.

RELATIONS OF VASCULAR DISEASE TO HEART DISEASE.

BY WILLIAM H. THOMSON, M. D., LL. D.,

NEW YORK,

PHYSICIAN TO THE ROOSEVELT HOSPITAL.

As the heart seems to be constructed with its cavities and valves fitted to act more than any other bodily organ on mechanical principles, like a simple pump in fact, it is natural to invoke mechanical principles to account for its disorders. Thus, when in the walls of the vessels through which it has to drive the blood, alterations occur which seriously diminish the calibre and elasticity of those tubes, it is readily inferred that the increased work thus entailed on the heart must in time afford us both the cause and the explanation of the consecutive heart lesions. But anatomical investigation and clinical experience abundantly demonstrate that the connection between vascular disease and heart disease is by no means so direct and simple that mechanical explanations will suffice to make everything plain. Thus, Mott reports that in the necropsies of 113 males and 81 females, or 194 in all, who had been inmates of the Claybury Insane Asylum, in each of whom extensive atheroma of the aorta and its branches was found, only 4 showed marked hypertrophy of the heart. On the other hand, at the Charing Cross Hospital, London, fully 24 per cent. of males and 7 per cent. of females with atheromatous arteries showed severe heart lesions. The difference between these two classes lay in the fact that the asylum patients usually had been long confined to the asylum where they were either in bed or led physically inactive lives, while the hospital patients were directly admitted from hard-working people, like porters and dockyard laborers. Again, as an example of the effects of bodily inactivity, the most extreme alterations in arteries are met with in senile degenerations, where every main artery of the body may be found stiff and extensively calcareous, and yet, in more than half, the heart will be found small.

We have to go much further to establish the connection which undoubtedly exists between vascular and heart disease, and in so doing we traverse one of the widest and most important fields of general pathology, which brings us directly to the subject itself of the nature and import of sclerotic changes in tissues.

Sclerosis in general is a substitution of the least living and most mechanical tissue of the body, the connective tissue, for some higher tissue which it replaces when that dies. In the blood-vessels, in both arteries and veins, we find it in more or less diffused patches, embedded in the intima just within the endothelial layer, and at first sight it looks like the result of some localized inflammatory process. But this is a mistake. At no time, in the great majority of cases, do the affected areas show infiltration with inflammatory products, so that it is erroneous to speak of an atheromatous artery as be-

coming so by endarteritis. There is no resemblance between the initial changes in the intima of the arteries in this case and the changes in the lining of the heart in endocarditis. What happens first in the artery is a degeneration and death of the muscular and elastic fibres of the middle coat, which, if not provided against in some way, would be followed by aneurysm or rupture from intravascular pressure wherever such degeneration occurred. To prevent this, the subendothelial connective tissue corpuscles actively proliferate and fill up the space left by the removal of the elements of the muscular coat, just as a plumber stops a leak in a pipe with solder. Even when this new product assumes a nodular form and may impart a beaded feel to the affected artery, Thoma, to whose researches we owe the most thorough investigation of this subject, has shown that it does not project into the lumen of the vessel, but projects the other way so as to fill up the space left by the absorption of the degenerated debris in the middle coat. Subsequent contraction of the sclerotic tissue may greatly change the calibre of the vessel, but primarily the process is a conservative one, and does not itself constitute the disease scarcely more than the scars left by small-pox are parts of that disease. In other words, the true disease here is that process of degeneration and decay in the higher order of cells that form the middle coat of the vessel.

What is it, therefore, which first kills the cells of the middle coat and leads to compensatory sclerosis? Evidently quite a number of devitalizing agencies, some immediate and some remote in their modes of operation. One of the most immediate of these can be nothing else than the damaging effect of continuous intravascular strain. The distribution of atheroma shows this pretty conclusively. In the aorta it develops at the root, where the initial stress is the severest; then along the concave, rather than the convex, contour of the arch; then at bifurcations and in distributions where the impact of the blood current is strongest, until, where the sclerosis occurs very widely diffused, we find the arteries of the lower limbs the most frequently involved, the anterior tibial being the artery most often affected in the body. The frequency, therefore, with which the coronaries are affected is plainly due to their situation where they are subjected to the highest arterial pressure. The most decisive illustration, however, is found in the case of the pulmonary artery, which almost invariably shows no trace of atheroma, however extensively the aorta and its branches are affected. In cases of prolonged mitral stenosis, however, all this is changed, and the pulmonary artery may be found atheromatous throughout owing to the stress falling on it from this valvular defect. Likewise in veins, the branches of the portal vein may be found both sclerotic and calcareous in long-standing cases of portal obstruction.

But where are we to find the original seat of the obstruction to the current which causes this strain?

Neither in the aorta nor in any of its branches, for Thoma has shown by examination of sections that the lumen of these vessels is as wide as ever. As late results of the atheromatous change, the originally tough deposits may caseate and ulcerate, or calcareous matter may accumulate in them till the inner surface of the vessel becomes rough or the seat of thrombi; but such changes do not constitute essential grades of the process. The development of atheroma in the pulmonary artery in mitral stenosis, just cited, as well as in the portal system in cirrhosis of the liver, shows that the primary seat of the obstruction is beyond the vessels and in the area of the capillaries. This is further demonstrated by the fact that the most widely diffused and most serious sclerotic changes are to be found in the arterioles, just those vessels which have relatively the largest supply of the actively living muscular tissue whose one function is to produce movement. To find them most affected has but one meaning, and that is, that they have had the most work to do in the struggle against an obstruction beyond them.

It cannot be too clearly recognized that the arteries are but conduits to the capillary area. That no appreciable processes take place in them, but that it is in the capillary area that everything goes on. It is there that all the nutritive and all the chemical changes take place which make up the processes of life. According as the interchange is natural between the extracapillary and intracapillary fluids will the physical conditions of the coming current of blood in the arteries be normal. But let chemical or vital changes occur in the capillary area that interfere with the normal interchange through the walls of the capillaries, and the arterial flow must be correspondingly affected. A simple illustration of the chemical side of this subject is afforded in chlorosis, where diminished affinity between blood and tissues due to deficiency of the oxygen carrier, hæmoglobin, leads both to œdema at the periphery and to dilatation of the heart at the centre of the circulation. Hence, we come to the conclusion that, so far as the factor of intravascular strain is concerned in producing vascular disease, the original cause is to be located in unfavorable conditions within that area of the circulation which ministers directly to nutrition. The arteries become very palpable to touch because overfull with blood from obstruction further on, and the pulse rises in tension. Hypertrophy of the muscular coat of the arterioles follows, on account of increased work; but hypertrophy in a muscle is always at the expense of its reserve stock of vitality. All hypertrophied muscles degenerate sooner than normal muscles, and arterioles illustrate this law very fully.

We are thus brought to the remote, or ultimate, causes of this leading form of vascular disease, and they may be conveniently summed up under the term of *tissue poisons*. We will refer to the commonest of them in their order, as lead, gout, alcohol, intestinal ptomaines, kidney disease, and syphilis. Lead is a specific muscular

poison, but so far as it causes disease of the blood-vessels it seems to do so by inducing in some unknown way a general gouty condition. The arteries feel full, the pulse is incompressible, gouty arthritis follows, and tophi are often present in the ear cartilages. Ordinary gout, on the other hand, is one of the commonest causes of arterial atheroma and degeneration. That it is not uric acid alone which causes gout is shown by the clinical facts of the systemic associations of uric-acid gravel. Children may suffer from uric-acid calculi severely, and likewise many adults who yet never have gouty toes or gouty bronchitis or any of the other familiar troubles of the gouty state, nor, we may add, diseased blood vessels. Out of the great array of theories or facts bearing upon the ætiology of gout, the geographical distribution of the disease is the most significant, for it is endemic wherever fermented, in distinction from spirituous, liquors are used, while it is scarcely known where no liquors are taken. Thus, on the same island, England is the land of strong beer and of much gout; Scotland is the land of much whiskey, but not of gout. When a Scotchman is gouty he is taking something else besides his whiskey. So in America, in my young days, gout used to be an aristocratic disease because limited to those who took European wines. Everybody else took whiskey and only had gout if he took too much cider. At present gout has become wholly vulgarized among us by the imported German custom of lager-beer drinking. I once lived in a Mohammedan country where they use no liquors at all, and no one there knows what gout is. When, therefore, we find disease of the blood-vessels so commonly present in old beer drinkers, we can safely infer that a specific derangement of digestion furnishes the tissue poison, for a beverage is as much diet as solid food is, and this inference lends color to other inferences about the alimentary origin, so to speak, of much vascular and heart disease, as well as affords indications for therapeutics.

Alcohol causes tissue degeneration irrespective of gout. In lager beer which can produce gout the alcohol may be only from four to six per cent.; in whiskey it is from fifty-five to sixty per cent. With spirits, therefore, a man may readily soak his tissues with an agent which chemically alters the properties of living cells and particularly delays normal metabolism. Such treatment simply ages prematurely the nervous, muscular, and secretory cells, with accompanying signs of impeded circulation and weakened function everywhere, and it is in the atheromatous blood-vessels that this acquired senile decay most clearly expresses itself.

Many writers speak of sclerosis as the final stage of life which all must reach if they do not die sooner, and as people start with a varying stock of vitality according to what they inherit, so the arteries of many at fifty are as old as others at eighty. We do undoubtedly find hard and tortuous vessels in people in middle life with a family record of apoplexy, who have not been drinkers or

arteries, it produces localized necrosis before there is time for connective tissue repair, and thus leads to aneurysm on the supervention of any sudden strain. Aneurysm of the aorta, therefore, is oftener due to syphilis than to any one other cause. Syphilitic disease of the coronary arteries leads to fatty degeneration of the heart by blocking its nutritive blood, with clinical characteristics which we will soon note. It is an error to suppose that syphilitic arteritis is a late tertiary development of the disease, for it frequently occurs before the expiration of the first year after infection, though, as a rule, it develops earlier in the arteries of the brain than in the aorta.

We are now prepared to note how the coexistence of vascular disease may alter the conditions of the problems of heart disease, whether in a pathological, a clinical, or a therapeutical sense. Too often we find an embarrassed heart in a patient after middle life prescribed for with virtually the same remedies that are given to a young patient whose whole vascular system is yet intact, but whose heart has been disabled locally in its valves or its appendages by a carditis of a toxic origin as from acute rheumatism. For, while it is true that primary disorders of the heart affect the circulation in most patients after forty, we often find the converse equally true—that primary disorders of the circulation affect the heart, and that physical examination of the arteries may afford as important indications of the nature of cardiac disease as physical examination of the heart itself; and the same may be said of signs observable in the venous, lymphatic, and capillary systems. The circulation, in fact, is more extensive still in its course, for the rapid effects of a hypodermic injection show that the interstitial fluid outside the capillaries moves at a scarcely less rapid pace than the intravascular current, and many cases of labored heart's action, leading in time to serious organic changes in the heart, doubtless arise first in a disordered state of the interchange between the intracapillary and the extracapillary fluids. Recognizing, therefore, that in such cases the heart should be regarded as only a part of the apparatus of the circulation, and, as such, as simply taking its share in a general disease, we have with each patient to go all over him, not only as he is, but as he has been in his inheritance and in his modes of life.

Thus, one of the first questions to be considered is to what extent the nutrition of the walls of the heart itself is impaired by disease of its coronary arteries. This is notably the case when we have reason to suspect the effect of syphilis. One patient, for example, who gives no sign of valvular defect, yet shows a tendency to frequent sighing: his pulse has but little tension, but, instead, is rather slow and intermittent, especially upon exertion, and his heart impulse is feeble. In another case, we are called to see a comparatively young subject on account of alarming symptoms of heart failure, which suddenly set in after a muscular effort, especially after lifting. There is good reason for fear, in the case of such a patient, that

these symptoms may be due to the giving way of a localized degeneration caused primarily by the blocking of a coronary branch, and that death may suddenly end all. Here, the severity of the signs of failure in cardiac function compared with the absence of marked signs of organic change in either the heart or the system at large, should lead us to push "specific treatment" actively, enjoining as well the total avoidance of muscular strain.

On the other hand, there is a different class in whom there is no reason to suspect syphilis, and who do show evidences of more or less vascular disease. They give, however, more signs of intrinsic weakness of the heart than of anything else. The pulse is not sustained in any quality; the face, after either exertion or emotion, shows changes of color generally to yellowish paleness, and the patients cannot finish a long sentence without an extra inspiration or two. The heart impulse is very feeble, and there may, or may not, be physical signs of valvular defect or of cardiac dilatation. Mural weakness is to be inferred as the chief danger of the patient, and that, again, is most likely due to coronary disease. It is noteworthy, however, what a great improvement, at least for a time, may occur in such patients by treatment. About eighteen months ago a well-known Western capitalist came to me with a serious train of these cardiac symptoms, which, though he had no valvular lesion, had induced several alarming attacks of pulmonary engorgement. He faithfully followed my directions for six months, and not only was he able to engage again in business, but he went safely through an accident in which he broke three ribs. Last spring, however, he took a trip to Europe, and, contrary to my advice, went to Nauheim. I warned him, and the physician who was to accompany him, that the Nauheim treatment was not adapted to his case. That physician has published a paper on the outcome of his patron's experience there, in which he says: "The usual number of baths (at Nauheim) is from twenty to twenty-four, ranging over a period of from four to six weeks. However, Professor Schott kept Mr. — in Nauheim from May to August 13th, during which time about sixty baths were administered. It is but feeble language to say that (after this) my resources were taxed to the utmost, and the marvel is that Mr. — ever reached America alive."

We may add that in all cases where, along with a weak or imperceptible apex beat, the pulse and complexion show signs of fatty degeneration in the ventricles, digitalis works badly, and so do some other remedial measures which may be of great service in the next class of cardiac disorders supervening on vascular disease. The symptoms at the heart itself will usually suffice to show the difference, especially when taken in connection with the ætiology of the trouble. Thus, in gouty patients, and in many cases of chronic alcoholism, the large fat hand with distended veins on its back, the swollen visage, and the œdematous ankles, go along with many other confirmatory signs of great embarrassment in every

tissue circulation. Meantime, the heart is found laboring powerfully with a widespread and heaving impulse, having grown large and strong in its efforts to cope with the peripheral obstruction. Later, the same patient is found waterlogged in his extremities and filling up in his serous cavities. The heart no longer strikes the chest wall forcibly, but with the short diffused slap of dilatation. It is doubtful if at any time, or at least in the beginning, the nutrition of the heart muscle in such cases was much impaired by coronary disease. The indications, therefore, are to relieve the tense arteries and the loaded veins by a prompt bleeding, followed by a calomel purge and digitalis, and, finally, by the true and permanent remedies which we will mention. It is in such cases that a judicious employment of stimulant baths may, after a while, do good. But what we would emphasize is, that these cases of cardiac disorder are really extrinsic to the heart itself in their origin, and that our chief aim should be to deal, as best we may, with those extrinsic causes and conditions.

For a long time albuminuria was used as a term equivalent to Bright's disease, but it is altogether too narrow a designation of kidney disease, especially of those forms of renal change which are most associated with vascular disease, for not only is the albuminuria in cases of granular kidney generally slight or even absent, but I also feel assured that albumin may not be found for years in many instances in which the kidneys have been steadily declining in their duty of eliminating urea, before the kidneys themselves become "granular." In those forms of Bright's disease characterized by dropsy and abundant albumin the blood-vessels and the heart in time become affected in proportion, not to the albuminuria, but to the failure of proper excretory function.

The pathology of granular kidney is extremely obscure, for in typical cases it comes the nearest of anything toward suggesting a sort of general spontaneous sclerosis all round, illustrated by wrinkled skin, emphysematous lungs, atrophied liver, and sclerosed nervous tracts, while the kidneys are neither more nor less wasted than the other viscera. The organ, however, which does not often waste, but rather hypertrophies, is the heart, as we might expect from the task it has to perform in driving the blood through so many well-nigh closed channels. The aorta suffers severely from the strain and the sclerosis at its root often involves the aortic valves with the production of corresponding auscultatory signs. Dr. Osler says that the combination of increased arterial tension, a palpable thickening of the arteries, hypertrophy of the left ventricle, and accentuation of the aortic second sound are signs pathognomonic of general arteriosclerosis. We may add that if, after a ringing metallic snap with the second sound, an aortic murmur begins to be heard, we cannot too soon warn our patient that an uphill bicycle ride may be the beginning of his end so far as danger from his heart is concerned, if he is not ended sooner by a cerebral hæmorrhage.

Therapeutically, our chief aims in cardiovascular disease should be prophylaxis, delay of a progressive process, and relief of symptoms. We can take comfort in the fact that the structure of the lungs, liver, and kidneys indicates that we start in life with about four times the stock of apparatus that we need to live with, and if our inventory of cells amounts, after middle life, to only half the original, we can get along, provided we do not trade as if we still had the whole. Notwithstanding sclerotic evidences of pretty general cellular death, we never can tell how much is yet left to go on with. Therefore, the first thing to do in cardiovascular disease is to take the chemistry of life in hand. Thus, we begin with diet, and study how we can thereby render the digestive processes easier, with consequent easier tissue metabolism, and, as a result, the least difficult products to excrete. The use of beer, alcohol, tobacco, strong meats, and such like articles, as well as too much of anything, are to be warned against, while a schedule, carefully studied for each patient's peculiarities, is enjoined, with explanations of the reasons.

There is one substance, however, which we may now call a food, whose importance as an agent to prevent muscular decay and degeneration is scarcely ever adequately appreciated, and that is oxygen. The more any animal breathes, the stronger its muscles, striped or unstriped. The muscular fibres of the heart and arteries of a sedentary indoor-living man or woman, cannot be as strong as the same fibres in an actively breathing man, any more than their arms and legs can. Muscular function, more than any other function in the body, is dependent upon the supply of oxygen which the muscles receive. The efficacy of the open-air treatment of tuberculosis is nothing compared with the efficacy of the open air for months together in such conditions of unstriped muscle weakness as obtain in chronic cystitis, chronic bronchitis, chronic gastro-intestinal atony, and, lastly, chronic cardiovascular disease. But in addition to the direct revivifying effect upon dying muscle, oxygen is our chief restorative for remedying the vitiated chemistry in the tissues which constitutes the "uric-acid diathesis" or causes the vital processes to be half smothered by alcohol or produces the dismal poisons of chronic dyspepsia.

It is high time that the profession should take up the open-air treatment for arteriocapillary fibrosis and prescribe such treatment for it in a very different fashion from the usual little-studied prescription that the sufferer should take a vacation. Long before this we ought to have appreciated better why it is that a dyspnoic man goes out for a short outing after trout and returns with his high-tension pulse soft, his wind restored, and his portal obstruction removed.

The other remedies, medicinal and otherwise, for symptoms or accompanying complications of cardiovascular disease, would take us too far afield for the limits of this article.

Therapeutical Notes.

The Treatment of Grippe.—M. H. Hervieux (*Union médicale du Canada*, April), in a general review of the subject, says G. Lyon believes strongly in quinine and antipyrine, while the author puts confidence in quinine and phenacetine.

For the *mild form* of the disease:

℞ Antipyrine. 12 grains;
Quinine hydrochloride or hydro-
bromide. 5 “

M.
For one wafer. Three or four daily for an adult.

Or:
℞ Phenacetine. 5 grains;
Quinine sulphate. from 2 to 4 “

M.
For one wafer. One every four hours till the effect is attained.

It is well to follow the ingestion of either of these wafers with a small glass of light grog.

Where *nervous prostration* predominates, the following is recommended:

℞ Strychnine sulphate. $\frac{1}{8}$ th of a grain;
Sodium benzoate. 75 grains;
Old brandy. 5 drachms;
Water. 3 $\frac{1}{2}$ ounces.

M.
To be taken in divided doses in the course of twenty-four hours.

When the nervous grippe has *cerebellar symptoms*, *e. g.*, dyspnoea without pulmonary cause, M. Huchard recommends the subcutaneous injection, three or four times daily, of a quarter of a Pravaz-syringeful of the following:

℞ Solution of trinitrin, 1 per cent. 40 drops;
Distilled water. 2 $\frac{1}{2}$ drachms.

M.
Nerve tonics will be needed after this form of grippe and, if there are symptoms of pseudomeningitis, hot baths and an ice bag to the head are called for.

Gastro-intestinal Grippe.—In this form there is a characteristic porcelain-like appearance of the tongue, or perhaps furring, bitterness in the mouth, absolute anorexia, sometimes vomiting and foetid diarrhoea, with, occasionally, gingivostomatitis. A mouth-wash of borax or other antiseptic is needed, and the gums may be treated with the following application:

℞ Salol. 1 $\frac{1}{2}$ drachm;
Vaseline. 1 $\frac{1}{4}$ ounce.

M.
If there is much turgidity of the gums:

℞ Tincture of aconite, } equal parts.
Tincture of iodine, }

M. for local application.

Internally, antiseptics of the digestive tube must be maintained by benzonaphthol, salophene (ten grains three times daily), or salol (from five to ten grains three times daily). These drugs may be administered alone or with quinine, in wafers.

Intestinal lavage, morning and evening, is indicated. Enterocolysis with tepid baths is recommended in the pseudotyphoid form. Abundant drink is necessary.

Pulmonary and Cardiac Grippe.—Tracheobronchitis, with a fatiguing paroxysmal cough, is the most common form. Codeine, half a grain in wafers or tablets every two or four hours, is recommended. Or:

℞ Tincture of aconite. 100 drops;
Cherry-laurel water. 3 $\frac{1}{3}$ ounces;
Syrup of tolu. 10 “

M.
A dessertspoonful repeated several times in the twenty-four hours.

Or, again, the following prescription by Huchard:

℞ Quinine sulphate, } of each. 30 grains;
Extract of cinchona, }
Extract of aconite root. 2 “

M.
For twenty pills. Three pills twice daily.

Inhalations of hot borated steam, with benzoin, mint, etc., are very useful. The atmosphere of the room may be charged with tar vapor.

In the *bronchitic form* with scanty difficult expectoration, ipecacuanha in nauseating doses or small doses of Dover's powder, squill, ammoniacals, etc., may be given. But where the expectoration is abundant and purulent, terpene in pills or wafers, from three to five grains, three or four times daily, or other balsamics or terebinthines. Beechwood creosote is also useful.

For *pulmonary congestion*, Grassé recommends:

℞ Ipecacuanha. 30 grains;
Bitter-orange peel. 60 “
Boiling water. 3 $\frac{1}{2}$ ounces.

Infuse and add
Syrup of senega or of orange flowers, 1 ounce.

M.
One soup-spoonful every two hours. This mixture is contraindicated in profound adynamia.

Dover's powder and quinine fulfil the same end. Ergotin subcutaneously for hæmoptysis, stimulants, and cardiac tonics are of use in this form, especially injections of caffeine, sparteine, ether, strychnine or camphorated oil.

If there is acute asystolia with cardiac dilatation, $\frac{1}{120}$ th of a grain of digitalin may be used, preceded at night by a slight bleeding. But the digitalin must not be repeated on the following day.

Journal des praticiens for April 27th credits the following prescription to Dr. Chevalet:

℞ Quinine valerianate, }
Sodium benzoate. } of each. 3 $\frac{3}{4}$ grains;
Phenacetine, }
Caffeine. $\frac{3}{4}$ of a grain.

M.
For one wafer. One to be taken every four hours until the cessation of the headache, fever, and depression.

Yeast in the Secondary Infections of Tuberculosis.

—Dr. Julius Ullman (*Journal of the American Medical Association*, May 4th) says that, having seen brewer's yeast used with great effect in a case of pyogenic affection of the tonsil, in doses of from two to four ounces every three or four hours, he has used the brewer's yeast to combat the secondary pyogenic symptoms of ulcerating tuberculosis in which there were chills, hectic flushes, morning decline, evening rise of temperature, etc. Since using it there have been no further chills, no hectic flushes, and no night sweats.

The remedy is easily obtained fresh from any brewery. It may be taken in a tumbler without the addition of other liquid, and the author's experience is that it is well borne. If the stomach cannot tolerate it, a rectal enema of double the quantity may be given.

It has been shown, says Dr. Ullman, by Vaughan and others that the nucleins of the body have much to do

with giving to an organism its immunity. The various organs generating nuclealbumin and nucleic acid give to the body a substance which is destructive to microorganisms and their toxins. Brewer's yeast contains nucleic acid and is, therefore, an excellent therapeutic measure, and one which the author has not seen recommended for pyogenic infection, whether pyæmia, septico-pyæmia, or the secondary infections in tuberculosis, diabetes, typhoid, carcinoma, etc.

The Treatment of Leucorrhœa.—According to *Ἱατρικὴ Προοδος* for March, Snegnirov recommends a vaginal injection of lactic acid, three per cent.

The same journal gives the following formula:

℞ Potassium chlorate, } of each 30 parts;
Tincture of opium, }
Tar water. 470 "

M.

From two to three soup-spoonfuls in a quart of water as a vaginal injection night and morning.

The Treatment of Dental Neuralgia.—S. H. Creighton, D. D. S. (*Medical and Surgical Monitor*, April), says that the causes of dental neuralgia are almost exclusively local and may be classified into obvious causes and obscure causes.

A. Obvious causes are as follows: (1) Pulpitis, (2) putrescent teeth, (3) pyorrhœa, (4) recession of gums, (5) malposition of teeth, (6) substances under the gums.

B. Obscure causes are: (1) Dying of pulp, (2) pulpstones or nodules, (3) exostosis, (4) pericementitis, (5) necrosis, (6) periosteal thickening, (7) deposition of secondary dentine in pulp chamber, (8) unerupted or impacted teeth, (9) diseased antrum, (10) catarrhal conditions, (11) albuminuria, (12) anæmia.

Unquestionably the most confusing cases are those of reflex dental irritation, in which the real cause is not readily discernible, but far remote. By way of illustration, he says that Dr. Slater has recorded a case where the right arm was seriously affected; it became almost powerless, and was constantly in a state of aching pain. The patient could hardly grasp or hold anything in her right hand. Facial palsy occurred, with dimness of the right eye. A week later she had complete facial paralysis, deafness, and her right arm as before stated. The upper right wisdom tooth was removed. Before the patient left the house, the pain in the arm and the powerlessness had vanished. The patient was quite cured in a fortnight.

The treatment, of course, is first to remove the cause. Where relief does not follow thereon, the author gives the following: *Internally*, morphine; gelsemium; antipyrine; acetanilide, with codeine cautiously given as an auxiliary; cannabis indica; or, perhaps, the best of all, fluid extract of gelsemium and fluid extract of cannabis indica, five to ten drops, according to the age of the patient; given two hours apart. *Locally*, chloral-camphor; aconite; a combination of oleate of morphine, lanolin, and vaseline; menthol, thymol, and chloral, of each, eight parts; camphor water and alcohol, of each, ninety-six parts; dry heat. *Constitutional treatment* according to the patient's general constitution, habits, age, etc. If the attack is acute, the following will be found helpful: (a) Restriction of diet to vegetable only; (b) saline cathartics; (c) salicylates, iodides, with colchicum. *Chronic Disorders.*—Should there be a tendency to chronicity, build up with tonics of iron, arsenic, strychnine, cod-liver oil, and malt. Despite all efforts to discover a cause, there are many cases at present unexplainable. In such instances treat on general principles. Occasionally a case will refuse to yield to any of these measures. In such cases resort to surgical intervention.

nine, cod-liver oil, and malt. Despite all efforts to discover a cause, there are many cases at present unexplainable. In such instances treat on general principles. Occasionally a case will refuse to yield to any of these measures. In such cases resort to surgical intervention.

The Alimentation of the Newly-born.—According to the *Lyon médical* of April 14th, M. Budin says that after birth the infant takes little milk; up to the tenth day the quantity augments, and then remains stationary for a while. He has found the following mathematical formula: The necessary quantity for twenty-four hours is arrived at by multiplying by two the figure of the child's weight and suppressing a 0. Thus: A child of 2,500 grammes will require $250 \times 2 = 500$ grammes; one of 3,700 grammes, $370 \times 2 = 740$ grammes, and so on.

An Ointment for Rheumatic Pains.—Maurange (*Gazette hebdomadaire de médecine et de chirurgie*, April 18th) is credited with the following formula:

℞ Methyl salicylate (oil of wintergreen). 25 parts;
Guaiaicol, } of each 5 "
Oil of turpentine, }
Lanolin. 15 "
Vaseline. 25 "

M.

Apply rapidly, and cover the affected joint with an impermeable tissue.

A Mixture for Tympanites in Infants.—The *Gazette hebdomadaire de médecine et de chirurgie* for April 18th credits the following formula to the *Journal de médecine de Bordeaux*:

℞ Sodium sulphocarbonate. 3 to $7\frac{1}{2}$ grains;
Syrup of bitter-orange peel. 75 "
Peppermint water. 375 "

M. S.

A coffee-spoonful three times a day for two consecutive days.

A Liniment for the Pulmonary Manifestations of Influenza.—Bourget, of Lausanne (*Therapeutische Monatshefte*, 1901, No. 3; *Münchener medicinische Wochenschrift*, April 16th), recommends the following formula:

℞ Salicylic acid. 4 parts;
Methyl salicylate (oil of wintergreen). 10 "
Oil of eucalyptus. 5 "
Oil of sage. 3 "
Oil of nutmeg. 5 "
Camphorated oil. 30 "
Spirit of juniper. 120 "

M.

The whole surface of the chest is to be rubbed with the liniment. [The spirit of juniper (*spiritus juniperi* [Ger. Ph., 2d ed.]) is made by macerating 5 parts of juniper berries in 15 parts each of alcohol and water and distilling off 20 parts.]

The Treatment of Ileus with Atropine.—Demme (*Münchener medicinische Wochenschrift*, 1900, No. 48; *Clinica moderna*, April 3d) has obtained a cure after other measures had failed in two cases of ileus, with stercoraceous vomiting, by a single injection of one thirtieth of a grain of atropine (gramme 0.005) [This dose seems very large and should be carefully watched in its effects, if used.]

THE NEW YORK MEDICAL JOURNAL,
62-68 West Broadway.

NEW YORK, SATURDAY, MAY 18, 1901.

THE ST. PAUL MEETING OF THE AMERICAN
MEDICAL ASSOCIATION.

By the time this issue of the *Journal* reaches those of our readers who live in remote parts of the country, many of them will be making their final preparations for setting out to attend the annual meeting of the American Medical Association, to be held in St. Paul on the 4th, 5th, 6th, and 7th of June. If they have been prudent, they have already secured quarters, for there will undoubtedly be a large attendance. In addition to the usual preliminary affair of the meeting of the American Academy of Medicine, there is this year an important assembly of military surgeons to immediately precede the meeting of the national representative organization. To those who are to attend a meeting of the American Medical Association, and particularly to those who go as delegates, it is always advantageous to have some idea of the special features that are likely to mark the occasion.

In the *Journal* for April 20th, in an article entitled *The Growth of the American Medical Association*, we suggested in general terms certain lines along which, as it seemed to us, the association's work might be simplified and its present purposes more fully accomplished than is possible under its actual form of organization. We think we have since perceived indications that the matters we dealt with in that article are almost sure to come up for consideration. We hope—indeed, we expect—that they will be considered in the progressive spirit that animates the present chief officers of the association, persistence in the old ways, simply because they are old, being renounced in conformity to changed conditions. In short, we look for a reorganization of the association, at least for action that will lead to such a result in the near future.

Another matter that, we think, might well engage the association's serious attention—and it is one that some

of the prominent and deservedly influential members are already cherishing—is the question of giving the association's powerful aid to the Association of American Medical Colleges, perhaps (of course with the avoidance of an *ex-post-facto* rule) by its declining to receive as future delegates those whose qualifications for practice, aside from their having complied with State requirements, rest on a diploma from an American school which is not a member of the Association of American Medical Colleges, that is to say, a short-cut school. There are still too many of these stumbling-blocks. They should be rooted out, and the American Medical Association is quite capable of performing the task quickly and effectively.

Finally, there is the Pathological Exhibit, the fruit of the inspiration and enterprise of our brethren in Indiana. As we pointed out in the issue to which reference has already been made, that feature of the meeting, which was so appreciated at the Atlantic City meeting, is this year more snugly under the wing of the association. We regard it as highly important, however, that still greater prominence and support should be assured to it for all coming meetings of the association, and we hope that generous action to that end will be taken in St. Paul.

THE DEADLY INFLUENZA.

"WHAT'S in a name?" Generally nothing; sometimes everything. For many years preceding the present "influenza period" persons who felt the need of a high-sounding name for every ailment that attacked them applied the term influenza to coryza, sore throat, an ordinary catarrhal cough, or any other manifestation of what plainer people called a "cold." The Italian name had come down from the time of a former "influenza period." Whatever terrors it may have had for the laity in the early years of its use had vanished under the influence of its indiscriminate and senseless application to trivial affections. As for the French term *grippe*, early shortened by many into *grip*, it seems to have been in itself suggestive of triviality to most minds. And so the only two names under which the terrible disease in question is known to the world in general both conveyed a suggestion of the trifling if not of the amusing; as a consequence, the disease itself, though really one of the most destructive, came to be regarded as of little moment. The medical profession has not wholly escaped the notion of its insignificance, though every physician of any experience must now acknowledge to himself that influenza is

one of the leading destroyers of health and life. On this deliberate conviction he should act, freeing his mind utterly from his original conception of the disease, and cooperate with his local board of health in attempts to restrict its prevalence. Thus only can much be accomplished.

It is not that the direct, primary mortality of influenza is very great; perhaps we should be better off if it were, for we should at least be less given to the fatal error of underrating its gravity. But it leads to so many other serious conditions. Creeping along the Eustachian tube, it sets up purulent inflammation of the middle ear, and this extends often to the mastoid cells and in some instances to the brain. Descending upon the lungs, it sets up pneumonia, in itself a fearfully destructive disease, and paves the way for tuberculous infection. It is not, however, the mere crawling or burrowing of a local process that does all this mischief; influenza poisons the garrison before storming the citadel. Few other diseases so rapidly or invariably work that intense depression of the vital powers, that sapping of the natural resisting forces, so characteristic of influenza, and in the wake of none others follows such protracted exhaustion. Then, too, if Nature succeeds in forming any antitoxine, it is feeble and short-lived, for one attack leads to but brief immunity, if any at all, against others. Moreover, we as yet know of little in the way of treatment that is more than symptomatic, save that sore experience has taught some of us that the disease must be humored, so to speak, if we are to get the better of it—we must yield to the attack early, without a fight; take to bed at once, and keep it till the acute illness is entirely over.

It appears from the Chicago Health Department's *Bulletin* for March that, of late, pneumonia, often the result of influenza, has been the cause of more deaths in that city than were due to any other disease. We do not believe that Chicago is exceptional in that respect. We presume, however, that her vital statistics are kept with a degree of accuracy commensurate with the energetic way in which her sanitary officers deal with infectious disease. Let influenza, then, be generally recognized as a potent factor in the production of pneumonia and tuberculous pulmonary disease—in short, of a considerable percentage of the total mortality—during its periods of prevalence, which are now following alarmingly close upon each other; then possibly the ground will have been prepared for a virtual stamping out of the disease. We must commend the Chicago department's efforts in this direction most heartily.

"UREINE."

As a rule it is safe to take it for granted that an alleged discovery in medicine that is first heralded in the newspapers will turn out to be no discovery at all. Dr. William Ovid Moor's supposed discovery of a new and important constituent of the urine, which he called "ureine," seems to be no exception. Press dispatches last summer announced Dr. Moor's discovery as set forth before the Thirteenth International Medical Congress sitting in Paris. His paper, entitled *The Discovery of "Ureine," the Principal Organic Constituent of Urine and the True Cause of Uræmia*, was published in the *Medical Record* for September 1st. Though skeptical as to the genuineness of the alleged discovery, we allowed a very condensed abstract of the article to appear without comment in our issue for September 8th. We felt that the investigator had fallen into error, but we recognized that the error was not of a kind calculated to lead to calamity; it was to be corrected, though not hastily, for its full and convincing correction had to come from the chemists, and the medical profession could afford to wait for their verdict. It has come in the shape of an article entitled *Is there Such a Constituent of the Urine as "Ureine"?* by Dr. Walter S. Haines, professor of chemistry in Rush Medical College, Chicago, and Dr. Charles S. Woods, associate in chemistry in the same school, published in the April number of *Medicine*.

Dr. Moor described "ureine" as a viscid fluid, somewhat resembling glycerin, decomposing at a temperature of about 80° C. (176° F.), and almost equal in amount to all the other solid constituents of the urine put together. The Chicago chemists seem to have demonstrated the following facts: 1. The extreme improbability of a previously unknown proximate principle being shown at this late day to be present in large amount in normal urine. 2. The fallacy of the inference that some new constituent of the urine must be found to account for the blue coloration produced by the action of urine on potassium ferricyanide and ferric chloride; either uric acid or a urate will give rise to the color, as has long been laid down in various text-books of chemistry. 3. If the glycerin-like liquid termed "ureine" were really a proximate principle, it could not be evaporated to dryness, whereas the liquid obtained by Dr. Moor's process can be rendered absolutely dry by patient evaporation at a temperature of 65° C. (149° F.). 4. "Ureine" is simply a somewhat concentrated solution of certain solids (the normal solids of the urine plus some of the reagents employed) in water. 5. No substance of the specific gravity of 1.270 (assigned to "ureine" by Dr. Moor) could fail,

if added to the urinary constituents already known, to materially affect the specific gravity of normal urine as fully accounted for by those previously well-known constituents. 6. If "ureine," which is said to be decomposed at 80° C. (176° F.), were the toxic principle of urine, that excretion would be deprived of its poisonous quality if subjected to a temperature considerably below the boiling point, but boiled urine is well known to preserve its toxicity.

A physician, no matter what may be his attainments in medicine proper, may readily fall into error in regard to a matter of chemistry. Such an error is not at all to his discredit, and we do not doubt that in this instance Dr. Moor will share with the profession at large a sense of obligation to Dr. Haines and Dr. Woods for having been at the pains to clear up the question of "ureine" definitively.

A GOOD-NATURED SATIRE.

WE have always been ready to applaud when a medical man has tried his hand in general literature, and we welcome Dr. John H. Girdner's recent satire on New Yorkers, in spite of its whimsical title.* Dr. Girdner is himself a typical New Yorker, though a Southerner by birth and rearing, so we Gothamites may readily preserve our equilibrium under his sometimes caustic sallies, which, by the way, seem to us to be quite as applicable to the people of almost any large town as to the inhabitants of New York. His personality is so genial that everybody who knows him will feel that, with all New York's faults, he loves her still, as we all do, and will even pardon him for defining a victim of "Newyorkitis" as a man who "has got his New York inflamed" and for injecting his political opinions into a homily upon subjects of no obvious political bearings. There is much that is wholesome and entertaining in the book, and doubtless it will meet with a wide circle of readers.

SALICYLIC ACID IN THE TREATMENT OF INFLUENZA.

THOUGH its curative power must be of decidedly restricted range in influenza—practically limited, we should say, to that form of the disease in which catarrh of the air-passages is a prominent feature—an aseptic condition of the inspired air seems to be largely what Bourget (*Therapeutische Monatshefte*, 1901, No. 3; *Centralblatt für innere Medizin*) relies upon in the salicylic-acid treatment. He paints the entire thorax with an aromatic liniment of a volatile compound of salicylic acid, and the warmth of the body, the patient being in bed and

well covered, soon volatilizes the salicylic compound, which at once pervades the inspired air.

THE NEW YORK STATE HOSPITAL FOR THE CARE OF CRIPPLED AND DEFORMED CHILDREN.

THE opening of this new institution, which promises to be of much usefulness, took place in Tarrytown on Friday, May 17th. It was auspicious for the hospital that such eminent men as Bishop Potter, Dr. Robert F. Weir, Dr. A. Alexander Smith, and Dr. William M. Polk took part in the exercises, the medical men representing respectively Columbia University, the New York University, and Cornell University.

IN HONOR OF THE LADY DOCTOR.

THE gallant Marcel Baudouin, in an article in the *Gazette médicale de Paris* for February 23d on The Women Physicians of Ancient Greece, justifies his practice of appending the name of their husbands to that of those women doctors who were married, unauthorized though it is from a classical point of view, on the ground that it is useful to facilitate further bibliographical research. He then adds: "Moreover, it is the only means of rescuing from oblivion the names of the husbands who have at least had the merit of making such glorious marriages." We congratulate our lady colleagues as well as M. Marcel Baudouin upon this graceful compliment. Like mercy, "it blesseth him that gives and her that takes."

SO-CALLED MASTITIS ADOLESCENTIUM.

THAT morbid condition of the breasts which sometimes, even in boys, occurs at the time of puberty or a little later is commonly called mastitis, but Richard Adler, of Prague (*Deutsche medicinische Wochenschrift*, 1901, No. 5; *Deutsche Medizinisch-Zeitung*, March 14th), regards it as simply an expression of an unusually rapid or pronounced physiological development. Preferable to the ordinary treatment with tincture of iodine and mercurial ointment he finds the use of a celluloid shield for the breast, capacious enough to prevent all pressure on the nipple. It is held in place with sticking-plaster.

DIPHThERIA AMONG CATS.

CHICAGO is reported to be having an epidemic of diphtheria among cats. The amount of infectious disease transmitted by domestic pets is probably far greater than people generally have any idea of, and cats are especially sources of danger, owing to their "freedom of the house," even including the sanctity of the bed chamber. The cat, moreover, is said to be very susceptible to diphtheria, and it devolves upon the members of the profession attending in cases of diphtheria to properly instruct those concerned to this effect.

**Newyorkitis*. By John H. Girdner, M. D., etc. New York: The Grafton Press.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 20th: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.
TUESDAY, May 21st: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.
WEDNESDAY, May 22d: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.
THURSDAY, May 23d: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.
FRIDAY, May 24th: New York Clinical Society; New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society.
SATURDAY, May 25th: New York Medical and Surgical Society (private).

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending May 11, 1901:

Small-pox—United States and Insular.

Table with columns: Location, Dates, Cases, Deaths. Lists various locations like Sitka, Alaska, Los Angeles, California, etc., with corresponding case and death counts.

Small-pox—Foreign.

Table with columns: Location, Dates, Cases, Deaths. Lists foreign locations like Buenos Aires, Argentina, Prague, Austria, etc.

Table with columns: Location, Dates, Cases, Deaths. Lists international locations like Cairo, Egypt, Marseilles, France, Paris, France, etc.

Yellow Fever.

Table with columns: Location, Dates, Cases, Deaths. Lists Rio de Janeiro, Brazil and Havana, Cuba.

Cholera.

Table with columns: Location, Dates, Cases, Deaths. Lists Bombay, India and Madras, India.

Plague.

Table with columns: Location, Dates, Cases, Deaths. Lists Cape Town, Africa, Hong Kong, China, Bombay, India, Karachi, India, and Wakayama Ken, Japan.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending May 11, 1901:

Table with columns: Diseases, Week end'g May 4 (Cases, Deaths), Week end'g May 11 (Cases, Deaths). Lists Typhoid Fever, Scarlet Fever, Cerebro-spinal meningitis, Measles, Diphtheria and croup, Small-pox, and Tuberculosis.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from May 4 to May 11, 1901:

BLOCK, WILLIAM H., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.
EBER, ALBERT H., Captain and Assistant Surgeon, United States Volunteers. The leave granted him is extended fourteen days.
GIRARD, JOSEPH B., Lieutenant-Colonel and Deputy Surgeon-General, is granted leave of absence for seven days.
JONES, PERCY L., Captain and Assistant Surgeon, will report at San Francisco for transportation to Manila.
PALMER, FREDERICK W., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.
SWIFT, EUOENE L., Major and Surgeon, United States Volunteers, will proceed from San Francisco to Washington for instructions.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending May 11, 1901:

BENTON, F. L., Assistant Surgeon. Detached from the Naval Hospital, Yokohama, Japan, and ordered to duty on the Asiatic Station.
BOOERT, E. S., Passed Assistant Surgeon. Ordered to the Lancaster.

CURTIS, L. W., Surgeon. Detached from the *Vermont* and ordered home, and to be in readiness for sea duty.
 DERR, E. Z., Medical Director. Detached from the Naval Academy, Annapolis, and ordered home to await orders.
 LOWNDES, C. H. T., Surgeon. Detached from the *Lancaster* and ordered to the Naval Station, San Juan, Porto Rico.
 PICKRELL, G., Surgeon. Ordered to the *Vermont*.
 STOKES, C. F., Surgeon. Detached from the Asiatic Station and ordered home.
 TAYLOR, J. S., Assistant Surgeon. Detached from the *Manila* and ordered to the Naval Hospital, Yokohama, Japan.
 WIEBER, F. W. F., Surgeon. Detached from the Naval Station, San Juan, Porto Rico, and ordered to the Naval Academy, Annapolis.

A Monument to Pasteur is to be erected at Dôle, his native place. It will be inaugurated in 1902.

The Willard Parker and Reception Hospitals.—Dr. Louis Fischer has been appointed a visiting physician to the Willard Parker and Reception hospitals, of this city.

Willard State Hospital Funds Tied Up by Failure of a Banking House.—Fifteen thousand dollars of New York State funds is tied up in the failure of the banking house of Le Roy C. Partridge, of Ovid, Seneca county, which was the chief depository of the Willard State Hospital. The State is protected, however, by a bond of \$25,000.

The Erie County Society for the Prevention of Tuberculosis, the second of its kind to be formed in the United States, has organized by the election of Dr. Benjamin G. Long, president; Dr. Henry R. Hopkins, vice-president; Dr. William G. Bissell, secretary, and Dr. Albert H. Briggs, treasurer. A board of fifteen directors has been chosen.

The Nathan Lewis Hatfield Prize for Original Research in Medicine, given by the College of Physicians of Philadelphia, has been awarded to Professor H. F. Harris, M. D., of Atlanta, Ga. The prize consists of the sum of \$500 for an original research, conducted at the instance of the committee, entitled: A Study of the Alterations Produced in the Large Intestine of Dogs by the *Amaba coli*, by Heat, and by Various Chemical Substances, with Notes on the Anatomy and Histology of the Viscus.

The National Confederation of State Medical Examining and Licensing Boards will meet at St. Paul on June 3d, just prior to the meeting of the American Medical Association in that city. There will be a discussion of the question What should be the Legal Definition of the Practice of Medicine? following a paper on that subject by Dr. Henry Beates, Jr., of Philadelphia; also a discussion following the report of the Committee on Interstate Reciprocity and Uniform Medical Legislation. Further information concerning the meeting may be obtained by addressing the secretary, Dr. A. Walter Suiter, Herkimer, N. Y.

The New York Pathological Society's Protest in re the State Pathological Institute.—At the meeting of the New York Pathological Society at the Academy of Medicine, on May 8th, the president, Dr. Edward K. Dunham, in the chair, resolutions were adopted protesting against "the subversion of the scientific work of the Pathological Institute of the New York State Hospitals, in the face of appeals from many medical societies of this city and State, in utter disregard of the appeals of distinguished medical men and prominent scientific men

both in this country and abroad for the continuance of the institute's work along its present lines of organization." The society also requested Governor Odell to intervene in behalf of this institute and to protect its work.

The New York University will Appeal in Medical School Property Case.—The decisions in the cases in which the New York University lost and the Medical College Laboratory and the Loomis Laboratory won, handed down by Justice Truax, in the Supreme Court, New York, will be appealed to the Appellate Division of the Supreme Court by the university. By the decisions the medical school property in East Twenty-sixth Street, including its contents, valued at \$150,000, is to be transferred by the New York University to the Medical College Laboratory corporation, and it is held that the Loomis Laboratory, in East Twenty-sixth Street, now allied with Cornell University, is not held in trust for the New York University.

The University Loses Control of the Medical College Laboratory.—When the Bellevue and University schools were consolidated, the Medical College Laboratory of the City of New York transferred to the university its property, including the laboratory and school, in consideration of a promise that the medical committee of the university should always remain constituted of people who were acceptable and satisfactory to the governing faculty of the college; that vacancies occurring in this committee should be filled by the appointment of persons who were agreeable and acceptable to the college, and that that committee should have the entire management and control of the property. The Medical College Laboratory, finding that this agreement was not being adhered to by the university, brought suit to set aside the conveyance of the property. In opposing this motion, the university set forth that if the committee of the university had made any such promise it had acted without authority. A decision in favor of the Medical College Laboratory was handed down on May 7th in the Supreme Court by Justice Truax, in which the university was ordered to reconvey all the property to the Medical College Laboratory and to pay all the costs in the case, the justice holding that the agreement was an integral part of the transaction and was, in fact, the sole consideration given by the university; and that, if the committee had acted without its authority in making this agreement, the entire transaction was illegal and the university could not profit by it. On the same day the suit of the university against the Loomis Laboratory, based upon the contention that the laboratory was held in trust for the university, was decided adversely to the university, which is thereby denied control of the laboratory.

The Iowa State Medical Association held its semi-centennial meeting at Davenport, Iowa, on May 15th, 16th, and 17th.

The Medical Society of the State of North Carolina will hold its forty-eighth annual meeting at Durham on May 21st, 22d, and 23d. An attractive programme of papers has been prepared.

The Mexico and Audrain Medical Society, of Mexico, Mo., has selected delegates to the State Medical Association at Jefferson City, this month, and the American Medical Association at St. Paul in June. As delegates to the former Dr. J. Rule, Dr. Fritts, Dr. E. McD. Bridgford, and Dr. Eugene Hultz were selected, and Dr. Fritts and Dr. G. F. Toalson were named for the latter.

The American Congress of Tuberculosis and the Medico-Legal Society met in joint session at the Hotel Majestic, New York, on May 15th and 16th. There were delegates from many of the States and Territories and from Canada, Mexico, and Nicaragua. All of the South American States were asked to send delegates. Among the subjects discussed were preventive legislation, the treatment and cure of tuberculosis, and climatic conditions.

The St. Louis Medical Society, of Missouri, held a meeting in that city on May 4th, at which the following papers were presented: A New Technique for the Reduction of Hypertrophies of the Turbinal Bodies, by Dr. M. A. Goldstein; Report of a Case of Osteosarcoma of the Forearm (Rapid Development), with Presentation of Specimen; also a Case of Mucoid Colitis, by Dr. J. W. Smith.

At the meeting held on May 11th Dr. J. W. Smith presented a Report of a Case of Suppurative Pericarditis (Operation and Recovery); and Dr. C. A. Martin presented an Unusual Case of Epilepsy.

The Medical Society of the County of Westchester will hold its annual meeting on Tuesday, May 21, 1901, at Grace Parish House, White Plains. Programme: I. Regular order of business. II. Address by retiring president. III. Election of officers. IV. Paper on Some Phases of Medical Legislation, by Dr. M. J. Lewi, secretary to the New York State Board of Medical Examiners. The discussion will be led by Dr. F. Van Fleet (chairman of the Committee on Legislation, Medical Society of the State of New York), Dr. Robert T. Morris and Mr. C. S. Andrews (council of the New York County Medical Society). V. Paper on Cancer of the Uterus, by Dr. A. F. Currier.

The New York Academy of Medicine.—The Section on Ophthalmology will hold its stated meeting on Monday evening, May 20th, at 8.15 o'clock. The order of business is as follows: I. Presentation of new instruments, corneal microscope with oblique illumination, by Dr. C. Koller. II. Presentation of specimens and patients—(a) Specimen, tubercle of the iris, by Dr. A. N. Alling; (b) patient with cyst of the vitreous at the head of the optic nerve, by Dr. C. Koller; (c) transplantation of a large Wolff graft into the orbit, to permit the wearing of an artificial eye, with exhibition of three patients, by Dr. Charles H. May; (d) patient with permanent conjugate deviation, by Dr. E. L. Meierhof; (e) patient with unilateral nystagmus, by Dr. A. Schapring; (f) Report of a Case of Xerosis Conjunctivæ Epithelialis, by Dr. J. E. Weeks; (g) Remarks on the Technique of Extracting Hypermature Cataract, with Demonstration of a Case, by Dr. H. Knapp. III. Paper, A New Operative Procedure for Treating Inflammation at the Posterior Part of the Eye, by Dr. S. B. Allen.

The American Pædiatric Society will hold its thirteenth annual meeting at Niagara Falls, N. Y., May 27th, 28th, and 29th. Following is the order of business: President's Address, by Dr. William D. Booker, Baltimore; The Visceral Lesion of the Erythema Group of Skin Diseases in Young Children; Congenital Absence of the Abdominal Muscles with Distended and Hypertrophied Urinary Bladder in a Child of Six Years, by Dr. William Osler, Baltimore; The Feeding of an Incubator Baby, by Dr. Charles W. Townsend, Boston; Glass Sun Rooms on City Roofs, or Winter Playhouses, by Dr. W. P. Northrup, New York; An Account of an

Epidemic of Malaria in Children, by Dr. Rowland G. Freeman, New York; An Analysis of Thirty-two Cases of Congenital Heart Disease, by Dr. John Lovett Morse, Boston; A Study of 571 Cases of Summer Diarrhœa, by Dr. Charles Gilmore Kerley, New York; A Note on the Little Finger of the Mongolian Imbecile and of Normal Children, by Dr. J. Park West, Bellaire, Ohio; A Case of Pulmonary Gangrene in a Baby, by Dr. Walter Lester Carr, New York; Bulbar Symptoms in the Newly-born, by Dr. Irving M. Snow, Buffalo; A Case of Acute Hemorrhagic Nephritis Complicating Influenza in a Thirteen-months-old Baby, by Dr. D. J. Milton Miller, Philadelphia; (a) Amaurotic Family Idiocy, (b) Monster, by Dr. A. C. Cotton, Chicago; Cyclical Albuminuria, with Report of a Case, by Dr. Frank Spooner Churchill, Chicago; (a) Heart Leap, (b) Maternal Impressions (report of case), by Dr. B. K. Rachford, Cincinnati; Measles Complicated by Appendicitis, by Dr. Harold Williams, Boston; The Treatment of Tuberculosis, by Dr. B. K. Rachford, Cincinnati. Papers are also promised by Dr. F. Huber, New York; Dr. A. Seibert, New York; Dr. Rotch, Dr. Acker, Dr. Adams, and others.

Manhattan State Hospital Training School for Nurses.—The fourth annual graduation exercises will be held at Ward's Island on Wednesday, May 22d, at 4.30 p. m. The steamers of the hospital service will cross to Ward's Island and return from the pier foot of East One Hundred and Sixteenth Street, every fifteen minutes after three o'clock p. m. The hospital will be open for inspection before the commencement of the graduation exercises, and guests who desire to visit the wards, etc., are requested to cross not later than four o'clock.

Mount Sinai Hospital.—It is announced that at the laying of the cornerstone of the new Mount Sinai Hospital, at Fifth Avenue and One Hundredth Street, on May 22d, the speakers will be Governor Odell, President Seth Low, Randolph Guggenheimer, Edward Lauterbach, and Dr. Abraham Jacobi. The stone will be laid by the president of the hospital, Isaac Wallach. Over eight thousand invitations have been issued.

Births, Marriages, and Deaths.

Married.

JERAULD—HUDDLESTON.—In Buffalo, on Tuesday, May 7th. Dr. Frederick Niles Coligny Jerauld, United States Army, and Miss May Ruth Huddleston.

KNOTT—BRAITHWAITE.—In Plainfield, N. J., on Saturday, May 4th, Dr. Middleton O'Malley Knott and Miss Hilda M. Braithwaite.

MALONE—PECK.—In Chicago, on Tuesday, April 30th. Dr. W. F. Malone, of Milwaukee, and Miss Adelaide Peck.

NICHOLS—GOODRICH.—In Yankton, South Dakota, on Saturday, April 27th, Dr. H. B. Nichols and Miss Edith R. Goodrich.

SHAMBAUGH—CAPPS.—In Jacksonville, Illinois, on Thursday, May 2d, Dr. George Shambaugh, of Chicago, and Miss Edith Capps.

SNITCHER—KAIPER.—In Denver, on Wednesday, May 1st. Dr. H. C. Snitcher and Miss Ada B. Kaiper.

VOGT—ATKINSON.—In Brooklyn, on Tuesday, April 30th. Dr. Francis C. Vogt and Miss Elizabeth A. Atkinson.

YOUNG—GREAMBA.—In Denver, on Tuesday, April 30th. Dr. James M. Young, of Pueblo, Colorado, and Miss Nora Greamba.

Died.

BOUSHEY.—In San Francisco, on Monday, April 29th, Dr. Julius Boushey.

CASSIDY.—In Atchison, Kansas, on Wednesday, May 1st, Dr. Joseph Cassidy.

DEYO.—In Gardiner, N. Y., on Saturday, May 4th, Dr. Abraham Deyo, in the seventy-first year of his age.

HUMPHREY.—In Akron, Ohio, on Saturday, May 4th, Dr. Elwyn Humphrey.

JARVIS.—In Hartford, Connecticut, on Tuesday, May 7th, Dr. George C. Jarvis, in the sixty-seventh year of his age.

LOWRY.—In Cincinnati, on Saturday, May 4th, Dr. Edward Noble Lowry, in the thirty-fourth year of his age.

MITCHELL.—In Marshall, Illinois, on Friday, May 3d, Dr. Orlando Mitchell.

PERKINS.—In Philadelphia, on Monday, May 6th, Dr. E. Stanley Perkins, in the fifty-sixth year of his age.

THURSTON.—In Louisville, Kentucky, on Thursday, May 2d, Dr. John M. Thurston, in the seventy-seventh year of his age.

TITUS.—In Great Falls, Montana, on Saturday, May 4th, Dr. W. H. Titus, of Dupuyer, Montana, in the thirty-fourth year of his age.

TULL.—In Chicago, on Monday, May 6th, Dr. Edward E. Tull, in the thirtieth year of his age.

Obituaries.

CHARLES RICE, PHARM. M., PH. D.

DR. CHARLES RICE, who died at his residence, in the grounds of Bellevue Hospital, New York, on Monday, May 13th, was born in Munich, Bavaria, in 1841. He received his education in public and private schools and in seminaries at Passau, Vienna, and Munich. Having at an early age special opportunities of acquiring a knowledge of various languages, one of his relations being an accomplished classical scholar and master of several Oriental languages, he felt drawn toward linguistic studies, receiving encouragement and special instruction from several prominent scholars, among them Dr. Gaugengigl, of Passau, and Professor Marcus J. Müller and Abbot Hanneberg, of Munich. He came to the United States in 1862 and entered the navy on board the sloop-of-war *Jamestown*. After three years of service as surgeon's steward, or apothecary, on this vessel in a cruise around the world he was honorably discharged. When he returned to New York he was so ill with malarial fever that he became a patient in Bellevue Hospital. It was not long before he became convalescent, and his well-known dislike of being idle led to his asking Mr. John Frey, then apothecary of the hospital and superintendent of the General Drug Department, for something to do while his strength was being recovered. Mr. Frey provided occupation for him and soon came to such an appreciation of Mr. Rice's ability and his desirability as an assistant that Mr. Rice was given a permanent appointment. Being appointed apothecary of the Bureau of Medical and Surgical Relief, when this was first organized, he was subsequently promoted to a similar position at Bellevue Hospital; and having meanwhile continued his chemical studies under competent instructors, he received the appointment of chemist at the General Drug Department, and, finally, chemist of the Department of Public Charities and Correction, which office he held up to the time of his death, in addition to that of superintendent of the General Drug Department. In 1872 he came very near losing his life. At the request of the late Professor McCreery he undertook the manufacture of a small amount of apomorphine, at that time something of a chemical novelty. The process involved the heating of the ingredients in a sealed glass tube immersed in a bath of boiling oil, and while he was watching the progress of the operation, the tube burst and the hot oil was driven to the low ceiling and fell as a shower upon Mr. Rice's head. It was this experience which led to his formulating an application for burns

which has since been entitled "Rice's burn mixture" by others than himself, his title having been "glycerite of gelatin," or "glue-burn mixture." In 1877 he became chairman of the Pharmacopœia Committee of the American Pharmaceutical Association, which drafted the report adopted by the Convention for the Revision of the Pharmacopœia of 1880 as the basis for the sixth decennial revision. He was also elected a member of the Committee of Revision and Publication and became its chairman. He was also chosen chairman of the succeeding Pharmacopœial conventions of 1890 and 1900. In 1879 the University of the City of New York conferred upon him the honorary degree of doctor in philosophy, and in

CHARLES RICE, PHARM. M., PH. D.

1890 the New York Academy of Medicine elected him an honorary fellow. He was the associate editor of the *American Druggist* from 1876 to 1892.

A striking phase of Dr. Rice's personality was his phenomenal possession of intellectual ability in so many diverse directions. His eminence in the domain of pharmaceutical chemistry is well known; but there are but few who are aware of his accomplishments in other fields. He was remarkably proficient as a mathematician. As a philologist he was, of course, *au fait* in his native language, German, and was ultragrammatical and orthographical in English, while he read with ease in French, Italian, Spanish, Portuguese, Dutch, Latin, Greek, Hebrew, Arabic, Hindustanee, Sanscrit, Persian, and Pushto, and knew something of Russian, Chinese, and Japanese. According to the late Professor Whitney, of Yale University, Dr. Rice was one of the foremost Sanscrit scholars in this country. He was an active member of the German Oriental Society of Leipsic and Hallé and of the American Oriental Society, was a corresponding member of numerous scientific societies abroad, being connected in this way with the Société de pharmacie d'Anvers, the Colegio de Pharmaceuticos de Barcelona, the Sociedad de Historia Natural de Mexico, the Pharmaceutical Society of Athens (Greece), and the Société de pharmacie de Paris.

In Dr. Rice the city of New York has lost a faithful servant and the professions of medicine and pharmacy a most conscientious and honest exponent of all that was best calculated for their advancement.

Pith of Current Literature.

Medical News, May 11, 1901.

Practical Food Prescribing. By Dr. Floyd M. Crandall.—The author's suggestions are practical. He believes that all so-called infants' foods are deficient in one or all of the important elements, and directs attention once again to the importance of having good, clean cow's milk, when mother's milk for any reason is not available. He mentions the close relation that exists between the acidity in milk and the deleterious; and as milk with the least acid is, as a rule, freest from spore-bearing bacteria, he suggests that this fact be made use of in testing milk by means of alkaline tablets as counseled by Farrington. He objects to sterilization, but he advises Pasteurization when there is the least doubt as to the milk's cleanliness.

Studies in the Bacteriology of Typhoid Fever, with Special Reference to its Pathology, Diagnosis, and Hygiene. By Dr. Philip Hanson Hiss, Jr.—The author's hygienic conclusions are: The urine of typhoid-fever patients should always be disinfected. From a hygienic standpoint bacteriological examination of the urine of patients convalescing from typhoid fever is important and should never be omitted before patients are allowed to go at large, so that proper precautions may be taken to guard against dissemination of typhoid bacilli by the urine. This is, according to the author, an often neglected source of infection that should be seriously considered in the hygiene of typhoid fever. Fæces, of course, should be disinfected at all stages of the disease, but the organisms being present generally only from the beginning of the second week to the fall of the fever, and the patient during this period usually being confined to bed, the fæces are not such a source of infection at large as the urine. The bacilli may, on account of the lung and throat lesions, be present in the mouth of those suffering from typhoid fever, hence the expectoration should be disinfected, as well as all eating utensils, etc., used by the patients.

Restoration of Useful Vision in a Complicated Case of Acute Inflammatory Glaucoma of Ten Days' Duration, with Visual Acuity Reduced to the Perception of Light. By Dr. C. A. Veasey.

Rupture of the Right Kidney; Nephrectomy; Recovery. By Dr. G. R. Trowbridge.—In view of his experience in this case, the author concludes that, in cases of trauma of the kidney, it is best to do an exploratory operation, for by this means alone is it possible to learn the extent of the injury.

Medical Record, May 11, 1901.

The Toxic Origin of Neurasthenia and Melancholia. By Dr. M. Allen Starr.—The author refers particularly to a variety of neurasthenia that occurs either in poorly nourished women, or in men about the age of forty-five years, who have lived rather freely, have taken little care of their diet, have indulged in the use of alcohol and tobacco, and have neglected exercise. The chief characteristic of this type is the alternation of feelings and symptoms at different times of the day. The maximum of distress occurs after the sleep of night, and the author attributes the cause to a toxic agent that accumulates in the blood during the period of sleep, and is manufactured either in the intestines or in the stomach, inasmuch as activity in the digestive process appears to aid in the elimination of the poison. Indican or indoxyl is the one

thing prominent in the urine, but of its ætiological significance nothing can be said. A true knowledge of the active agents concerned will be obtained only by very much more exhaustive studies in the chemistry of digestion. The diet in each case should be considered separately; no general rule applies to all cases. Meats, fish, rice, macaroni, and hominy are available; meat soups, potatoes, turnips, beets, and cheese are not. To counteract the toxic agent, a combination of five grains of sodium sulphocarbonate with one grain of potassium permanganate, put up in a shellac-coated capsule, is of use, given after each meal and on retiring. Capsules of salol (five grains) and castor oil (ten minims) are also of use. A hot bath on rising, followed by a brisk cool sponging, is of importance. Moderate exercise should be insisted upon, and an outdoor life, if possible, counseled.

Potain's Simple and Accurate Method of the Percussion of the Heart (with Post-mortem Verifications) By Dr. George M. Converse.—The key to the percussion of the heart rests in the recognition of the differences of pitch of the percussion note, and not in differences of intensity of the sound. The taking and preserving of tracings on a transparent paper is the simplest, quickest, and only accurate method of describing a heart for future reference.

The Treatment of Pneumonia, Including the Hypodermic Injection of Saline Solution. By Dr. F. Neuhoff.—As to the status of the saline-infusion treatment in acute croupous pneumonia, the author concludes that it is a useful adjunct to other treatment in selected cases. It acts as a powerful heart stimulant when other heart remedies can no longer sustain the flagging circulation. It increases the secretions, and moistens the tongue and throat as well as the skin. It lessens the delirium. Other observers have noticed that it also improves the respiration. It is contraindicated in pulmonary œdema. Some pneumonia patients apparently die of collateral pulmonary œdema not consequent on a failing heart. In these cases, saline infusions are not applicable. Other pneumonia patients apparently die from heart failure, or a pulmonary œdema caused by heart failure. In this latter class of patients the saline infusion averts the tendency to death by sustaining the heart when nothing else can, and thus it gives additional time for a favorable turn to occur in the disease.

Syphilis in the Well-to-do. By Dr. J. A. McDonald.—The author is convinced that syphilis among those favored by fortune is a totally different disease from syphilis in the poor. The statistics adduced support this opinion, and the author's explanation is, that the rich man gets his syphilis from a fashionable prostitute whose syphilis is well treated and not severe, and, moreover, once infected, the rich man avails himself from the start, of medical attention and constant care. The author insists that, in any case, the physician should make it perfectly plain to his patient that a failure to submit to a thorough course of treatment for the full period of two years will, in all probability, lead to disaster.

Subarachnoid Spinal Cocainization as a Means of Inducing Surgical Anæsthesia. By Dr. E. N. Liell.—The author believes that this method has passed the experimental stage, and entertains the hope that it will have its field of practical usefulness in the near future along with ether, chloroform, and nitrous oxide.

Keloid Formed upon a Vaccination Scar. By Dr. Frederic Griffith.

A Successful Pylorectomy on a Man in his Seventy-first Year. By Dr. Alfred King.

Postural Treatment in Threatened Miscarriage. By Dr. Alice M. Smith.

Boston Medical and Surgical Journal, May 9, 1901.

Some Reported Cases of Typhoid Fever Attributed to Contaminated Oysters, with Certain Facts Concerning this Means of Infection. By Dr. Charles Harrington.—After giving several interesting cases, the author refers to the investigations of Chantemesse, who secured specimens of oysters from several sources and made bacteriological examinations thereon. He found an abundance of bacteria and, in many instances, the *Bacillus coli communis*. He placed some of the oysters in water infected with typhoid stools and cultures, and, after twenty-four hours, removed them and kept them another like period before subjecting them to a bacteriological test. They yielded the typhoid organisms and *Bacillus coli communis* in great numbers. The author, in general, believes that the danger of infection arises wholly from the presence of sewage in the water where the oysters are planted or stored. The remedy lies, either in transferring the beds to cleaner situations, or storing the contaminated oysters in clean sea water until the bacteria have either perished or been washed away. As to the length of time sufficient to insure purification: Some believe that a week is enough; others, that sixteen days should be allowed. They should not be stored where sewage can reach them by currents along the shore, or where the prevailing winds can exert a harmful influence to the same end.

Experience with the Widal Reaction in Typhoid Fever. By Dr. Charles F. Withington.—The usual ninety-five per cent. of successful results indicates the value of the Widal reaction as a diagnostic sign. In the opinion of the author, however, the limitations of the test as to the time of its first appearance, which is rarely before the sixth day, and often not before the ninth or tenth, are such as to deprive it of the value which one would like to attach to it for early diagnosis. The author gives a typical instance of the tardiness of the Widal response in a case, where, after eight consecutive failures, it was positive for the first time on the twenty-ninth day.

The Widal Reaction in Typhoid Fever. By Dr. George B. Shattuck.

Means of Infection in Typhoid Fever. By Dr. E. N. Whittier.—The author's experience has made him very apprehensive regarding the course of typhoid occurring in families whose summers have been passed away from the city—rural and not urban in the source of the infection, imported and not native, "malarial and not straight." The typhoid of city origin may be atypical and puzzling; care and restrictions may be as prolonged, but it is without the terror, the destructiveness, the lethal drift, characteristic of country typhoids.

Early Diagnosis of Typhoid Fever by Isolation of Bacillus Typhosus from Stools; Conclusions of Dr. L. Roney, Based on the Use of his Asparagin-lactose-carbol Gelatin. By Dr. Calvin G. Page.—The author believes that there is good reason to hope that a method will be devised by which a report of examination of feces can be made in less than three days.

The Fevers of the Philippines. A Preliminary Report on the Nature of the Fevers Prevalent in the Philippine Islands, Including Typhoid Fever, Malta

Fever, the Malarial Fevers, and Undetermined Tropical Fevers. By Dr. Joseph J. Curry.

Philadelphia Medical Journal, May 11, 1901.

The Doctor's Fee—A Plea for Honorable Dealing. By Dr. John B. Roberts.—The author insists upon the point that the province of the doctor is to relieve the sick and suffering, and to subordinate to that first object of his calling the obtaining of a financial reward for his labor. Various forms of selfishness and cupidity are dealt with, and, with particular emphasis, the practice of dividing the fee is condemned, as is also the practice of accepting commissions. The author believes that the doctor should have an estimate of the value of his services, operative or otherwise, fixed in his mind. The amount should be based on his experience and skill, and it should not be so low as to coax away unjustly the patients of the younger and less experienced men in the profession. This fee should be lessened when the financial position of the patient would make its payment a serious burden. A well-to-do patient should pay the full fee, which should be generous in order to recompense the doctor for his expensive education and hazardous life. The fee should not be increased, however, unless an unusual time is given to the service, or additional responsibility placed upon the physician by reason of the man's position.

The Ætiology of Arrested Mental Development. By Dr. Pearce Bailey.—The author divides the factors that interfere with the development of the brain of the child into three classes: (1) Those acting before birth; (2) those acting during birth; and (3), those acting during infancy and childhood. He believes that the eradication of degeneracy has its brightest hope in increased education and better State care. Teach boys and girls physiology, and young men and women the pathology of generation. This, he believes, is a step not difficult to accomplish, and would provide a certain protection to the normal. For the abnormal and degenerate, sequestration is the only solution. For advanced cases, institutions are the legitimate homes. But for the borderland cases, the feeble-minded, the half-insane, the drunkards, the tuberculous, and the epileptic, colonization is the surest means of caring for the future.

Cataract Extraction. By Dr. Edward Jackson.—That ripening operations are better than waiting for spontaneous maturity of cataract in many cases, the author believes there can be no question. Now, however, that we have learned that immature cataracts can be extracted with safety, their field of usefulness has largely disappeared. Cataract extraction has been less affected by the evolution of antiseptic than any other important surgical operation. It is done with recourse to few of the more pretentious procedures by which asepsis is supposed to be secured in other capital operations, and yet few, if any, surgical operations show a better record as regards infection. According to the author, this fact demonstrates that the line is yet to be drawn between essentials and non-essentials in the technique of aseptic surgery.

Abscess of the Orbit from Disease of the Ethmoid; Curetting through the Orbit and Draining through the Nose. By Dr. George C. Harlan.

Purulent Chorioiditis, Following an Attack of Mumps; Diagnosis. Metastatic Chorioiditis, Revised by Study of the Eucleated Eyeball. By Dr. John T. Carpenter.

Spontaneous [?] Rupture of the Spleen—Laparotomy—Death—Report of Case. By Dr. D. C. Howard.

Ephemeral Insanity, with Report of Two Cases. By Dr. Charles J. Aldrich.—The author's cases are interesting examples of this form of insanity which Clouston has described as "*mania transitoria*." Most of these cases, according to Clouston, are epileptiform; a few cases are seen in young persons of unstable nervous and mental organization and usually of intense neurotic heredity. However, none of these causes or predispositions seems to explain the advent of insanity in the author's case. The occurrence of such insanity, which has a duration of a few hours or a few days in an otherwise apparently healthy and normal individual, possesses not only great medical interest, but involves questions of forensic medicine that are tremendous in significance and scope.

Journal of the American Medical Association, May 11, 1901.

The Diagnosis and Treatment of Injuries of the Head. By Dr. James H. Dunn.—The first duty in all head injuries is a careful and systematic examination, and, for this purpose, it is always desirable, and usually necessary, to shave the whole head. The natural depressions of the skull should be particularly considered, as such irregularities may be mistaken for depressed fractures, or asserted to have been such later on in damage cases. The embossments and tumefactions caused by extracranial effusions of blood may also lead to errors of diagnosis unless carefully studied. The discharges of blood and serum from the ear or nose, the behavior of ecchymoses of the mastoid region, of the conjunctivæ, of the pharynx, etc., and the disturbance of function of cranial nerves—all these are of great importance. The author gives an instance typical of the class of injuries to the head without important local signs or definite focal symptoms. He also considers those cases in which there are signs of fracture of the base, but no localized cerebral symptoms. He believes that the technique of intracranial surgery is still extremely defective in that, as yet, we have no easy, rapid, and safe method of opening the skull, nor are we yet able to prevent a welding of all the tissues, brain membranes, and scalp into one scar, which often proves a source of cortical irritation. He asserts that the insertion of foreign substances between the dura and the cortex is wholly objectionable, and that, far from preventing adhesions, it usually increases them by the irritation which it excites, even under the most favorable conditions.

The Relation and Position of Pelvic Organs; Examination of Patients. By Dr. Franklin H. Marten.—The author believes that the bladder and rectum, contrary to the opinion of many writers, perform their normal functions without interfering with the position of the uterus. The free upper wall of the bladder does not lie in contact with the anterior wall of the uterus, that space, when not occupied by the bladder, normally distended, being filled with light, constantly moving small intestines. These act as movable upholstery, surround the uterus on all sides, equalizing the abdominal pressure, and fill the necessary vacuum. In the general examination of a gynæcological patient, it is due to ourselves that we eliminate, or if it is impossible to eliminate, at least recognize, any serious organic difficulty other than gynæcological. The author outlines a systematic plan for the local examination. The systematic examination of the abdomen soon establishes a habit

which will make an operator acute in detecting minor changes, and many things will be revealed which would never come out in a simple bimanual examination of the pelvis.

Four Cases of Calculi Impacted in the Ureter. Nephro-ureterectomy, Abdominal Uretero-lithotomy, Vaginal Uretero-lithotomy. By Dr. B. R. Schenck.

The Differential Diagnosis of Ectopic Pregnancy, with Especial Reference between it and that of Early Uterine Abortion. By Dr. Hiram N. Vineberg.—The points the author brings out are: 1. The frequency with which ectopic gestation is diagnosed as early uterine abortion. 2. The advisability of looking with suspicion upon every case presenting apparently the symptoms of early uterine abortion, and, if the case is not running a simple and natural course, of fully anæsthetizing the patient for a rigid examination and for the proper performance of curetting in the event of uterine abortion being present. 3. If, after carrying out this plan, there is still some doubt, the advisability of making a posterior vaginal exploratory incision to determine the presence or absence of blood in the peritoneal cavity and of being prepared to open the abdomen if the condition found calls for it. 4. The unreliability of the so-called pathognomonic signs or symptoms of ectopic gestation.

I. Union Following Pathological Fracture of the Femur Due to Secondary Carcinoma. II. Spontaneous Disappearance of Carcinoma of the Lip. By Dr. Leonard Freeman.

The Rational Use and Limitations of Therapeutic Measures Intended to Promote Absorption of Exudates within the Eyeball. Medicinal Measures. By Dr. Randolph Brunson.—The limitation of therapeutic remedies used to promote the absorption of exudates is very circumscribed in a way, and, after all has been said, alteratives, mercury, and iodides, pilocarpine, sodium salicylate, and the hot baths constitute about the whole number of remedies on which we can place much reliance. Exudates of specific and uric-acid origin can without question be controlled, but in other cases we are frequently disappointed, do what we may.

Suppurating Mastoiditis, with the Report of Cases; Suppurating Otitis Media, both Ears; Suppurating Mastoiditis on the Right Side, Abscess Extending into the Deeper Tissues of the Neck, and Extradural Abscess. By Dr. J. H. Bryan.

Remarks on the After-effects of Operations for the Removal of Adenoid Tissues at the Vault of the Pharynx. By Dr. E. L. Shurly.

Medical Treatment of Actinomycosis. By Dr. J. L. Sawyers.—In this paper the author asserts that actinomycosis is not an uncommon disease, and that where uncomplicated, it is a non-suppurative, afebrile, comparatively painless, slowly progressing disease. The clinical signs and symptoms are often pathognomonic. The club-shaped bodies, single and in asters, are often absent, the threads more frequently present, and the coccus-like bodies most constantly present. Combined surgical measures and the administration of potassium iodide give the best results. Potassium iodide, administered internally, cures a large percentage of cases. The interstitial injection of potassium iodide into the infected tissues exerts a strikingly salutary influence over the disease.

Tropical Abscess of the Liver. By Dr. E. F. Robinson.

The Prevention of Insanity. By Dr. Daniel R. Brower.

When should we Operate in Appendicitis? By Dr. Douglas C. Moriarta.

Operating under X-rays. By Dr. J. F. Baldwin.

Lancet, May 4, 1901.

Eczema in Relation to Age. By M. Morris, F.R.C.S.—Eczema presents certain well-marked differences corresponding to different ages in life, and the author classifies the subject as follows:

Eczema in Infancy.—The disease usually begins as a patch of seborrhœa, around which a red areola appears. Everything tending to increase the local blood supply should be avoided, such as scrubbing the head with soap and water, keeping the head covered, etc. In the first stage, the disease is a purely local condition and calls for no constitutional treatment. Strong ointments and lotions should not be used; the applications should be of an antiseptic character, one of the best being an ointment of five grains of precipitated sulphur to an ounce of benzoated lard. Improper food is not always the cause of the change of a dry scaly eczema to an acute condition; it may be due to vaccination, to intestinal worms, or other causes. In such acute cases the best drug to give internally is mercury in some form, such as calomel. To dry up the discharge in acute, weeping cases, the author recommends the use of a powder composed of equal parts of boric acid, starch, and oxide of zinc. Ichthyol is also of value in converting an acute into a subacute stage, very small quantities being used. This form of eczema, like all others, is cyclical in its nature.

Eczema in Childhood.—In children eczema is also generally of the seborrhœic type, and begins as rough and scaly patches upon the cheeks and forehead. The early recognition and treatment of these patches is of the greatest importance. A relapse is much less likely if the original scaly condition is treated at the beginning. Such children should not go away to school; they are far better treated at home. The author doubts very much whether any relation exists between eczema and teething.

Eczema at Puberty.—There are two chief forms of eczema beginning at puberty. One is the seborrhœic form, and the other is the form which is associated with dry skin—xeroderma. In the latter form it is essential that the dry condition of the skin should be treated by mollient baths, and the free application of a twenty-per-cent. solution of glycerin in water. Xeroderma usually attacks the flexor surfaces—the bends of the elbows and knees. That form of eczema which alternates with nerve attacks (asthma, rheumatoid arthritis), very often appears at puberty for the first time, and requires special internal treatment in the form of nerve tonics, etc.

Eczema in the Adult.—An otherwise perfectly healthy person may suddenly become subject to a severe general attack of eczema, following exposure to cold. In such cases nothing is better than small doses of tartrated antimony, repeated in an hour or two; one thirty-second of a grain is usually sufficient. The irritation of the skin left behind after the subsidence of such an acute attack is often most intense, though there may be nothing to be seen. In some cases nothing but a change of climate will prove of service. It is in this form of eczema that mineral-water treatment is most efficacious. The use of alcohol seems often to have a definite relationship to such general attacks of eczema. The disease often takes the form of intertrigo in adults, being localized around the scrotum and the inner side of the thigh. Ex-

ercise should be curtailed, and the parts bathed with an antiseptic lotion, dried, and a weak sulphur ointment applied accurately all over. Varicose eczema is also exceedingly common in adults; the treatment is rest in bed, with elevation of the leg, and the application of Unna's zinc glycerin jelly. Chronic eczema of the leg, in the form of small, circular, chronic patches, is often seen. A serious effort should be made to get rid of these patches, as the condition may become acute and extend all over the leg. Ointments of salicylic acid and resorcin, and of pyrogallic acid are recommended.

Eczema at the Menopause.—Two forms occur at the change of life: Acute eczema of the head and face, and the very acute eczema of the vulva and anus.

Eczema in Old Age.—The constant irritation and itching so common in the eczemas of old age, often leads to very serious results. There is loss of sleep, imperfect nutrition, etc., thus forming a vicious circle. It is not uncommon for old people to commit suicide on account of their eczema. In such cases there is only one drug of any service, and that is opium; it should be given freely.

The Action of Arsenic as Observed during the Recent Epidemic of Arsenic Poisoning. By Sir Thomas Lauder Brunton.—In this article the author gives a short account of the general action of arsenic upon the body, classifying the symptoms observed in the late epidemic of arsenical poisoning, rendering it easier both to remember them and to understand the varieties which have been described. In both the Manchester and Hyères epidemics there can be little doubt the symptoms were chiefly, if not entirely, due to arsenical poisoning. The discovery of selenium in beer imports a new factor into the question, but it is not yet settled whether this substance may be partly to blame for producing neuritis. The author is very doubtful as to the production of peripheral neuritis by alcohol, and suggests that alcoholic neuritis, so-called, may in reality be due to arsenical poisoning.

Some Further Investigations upon Rheumatic Fever. By Dr. F. J. Poynton and Dr. A. Paine.—In a preceding contribution the authors described a diplococcus, which they were able to isolate from the tissues in rheumatic fever, and which they thought to be a cause of rheumatic fever. They have continued their investigations and have now isolated the diplococcus from sixteen cases of rheumatic fever. They have succeeded in demonstrating the organisms in rheumatic nodules in two cases, and have in addition grown them in the nodular tissue outside of the body in pure culture. Intravenous inoculation of this culture has produced valvular inflammation, pericarditis, and polyarthritis in a rabbit, and the diplococcus isolated from its joint exudate.

The authors hold that the commencement of rheumatic chorea is associated with the presence of the diplococci in the brain, and perhaps the pia mater, as well as with the presence of toxines produced by these organisms. They have observed distinct choreic movements in a rabbit inoculated with the diplococcus, and have isolated the organism from the blood and from the cerebrospinal fluid. They review the pathological and bacteriological literature of chorea, the reported facts agreeing well with their hypothesis. That only certain cases should develop chorea is remarkable and cannot yet be explained, but it is only a further evidence of the remarkably specific action of the more complex poisons. The causal relation of fright to chorea is also a great difficulty. Rheumatism produces a cerebral state analogous to that produced by fright: what that condition is

we do not know. The diplococci have been demonstrated in the multiforminuclear leucocytes, so that the moderate leucocytosis which occurs in rheumatic fever may be looked upon as protective in nature. It does not seem probable that rheumatic fever has a definite incubation period. The authors' observations tend to show that the fever of rheumatism is a primary phenomenon, and not secondary to the local lesions only. The causes of the occurrence of ante-mortem thrombosis in the heart in rheumatic fever are probably various: mechanical difficulties, weakness of the heart wall, and the increased tendency of the blood to clot.

A Case of Perforating Gastric Ulcer with Rigors. Operation for Suture Followed Three Weeks Later by Volvulus and Acute Intestinal Obstruction Requiring a Second Laparotomy. By A. A. Bowlby, F. R. C. S., and J. F. Steedman, F. R. C. S.—The case here reported is interesting on account of the extraordinary vitality of the patient, who survived two days of peritonitis following perforation and the necessary operation for suture, as well as the strangulation of an immense quantity of small intestine and a very serious operation for its relief within three weeks of the first abdominal section.

On Serous Vaccinia in Connection with Cretinism and Rickets. By Dr. R. Kirk.—The author reports several cases of serous vaccinia, all of the patients showing subsequently signs of myxœdema or rickets. In serous vaccinia, instead of normal viscid lymph being produced at the point of inoculation, a vesicle forms which, when broken, discharges thin, watery serum. It would appear that we should recognize the existence of a serous as well as a hæmorrhagic diathesis; the two are closely related, and both are associated with great vulnerability of tissue by various morbid agents. The author raises the question whether a healthy thyreoid gland is necessary to produce the viscid lymph of normal vaccinia, and suggests that vaccination be performed on calves whose thyroids have been extirpated and the results noted. The viscosity of the lymph perhaps acts as a defence against micro-organismal invasion. In one family of rickety children, serous vaccinia occurred in six out of seven children.

Three Cases of Sarcoma of the Uterus. By Dr. E. O. Croft.—While sarcoma of the uterus is an uncommon disease, yet its rarity has been overestimated. The author reports three cases seen by him. In two of the cases the disease had progressed so far as to be unsuited to operation; in the third, the uterus was removed and the patient made a good recovery.

A Case of Recovery after Operation for Diffuse Peritonitis from Perforation of the Appendix. By Dr. R. Coombe.

On the Uses of Diphtheria Antitoxine. By T. B. Broadway, M. B.—The author wishes to impress on all that the serum treatment of diphtheria has placed the prognosis of this disease in a more favorable light, and, if used early, practically saves life; it preserves the patient from the serious sequelæ which often follow recovery from it; if proper antiseptic precautions are taken no abscesses form at the seat of injection; and the almost instantaneous relief it gives to distressing symptoms would alone justify its use. It should be used early, freely, and in all doubtful cases of sore throat. Of twenty-four cases treated with antitoxine, one died of cardiac failure; of six cases treated without antitoxine, two died.

The Respiratory Movements of the Præcordial Area in Health and Disease. By Dr. J. Aikman.—The au-

thor has found that in cases of pericarditis complicating rheumatism, a marked diminution of the respiratory movement in the third left intercostal space precedes the stethoscopic signs by a period varying from one to four days. This limitation of movement rapidly extends to the second and first intercostal spaces. In his experience this sign is invariably followed by the appearance of a pericardial friction and a dull percussion note. It disappears with recovery, and reappears before a relapse. The variations of chest movement which prognosticate and evidence endocarditis are less in degree, being less marked when the right side of the heart is involved.

British Medical Journal, May 4, 1901.

Functional Nerve Diseases. By Dr. G. E. Rennie.—By the expression "functional nerve diseases" the author means disturbances of function of the elements of the nervous system, whether in brain, cord, or peripheral nerves, which are not dependent on gross organic change in those elements. Clinically, four types can be recognized: (1) Feigned disease; (2) hysteria in its various manifestations; (3) neurasthenia; (4) functional disease concomitant with and dependent upon organic disease. These various types are discussed in a very general way. Among the points brought out are the following: In feigned epilepsy, an important sign may be obtained from the examination of the urine, as in epileptics it is markedly hypotonic as compared with normal urine. A study of the plantar reflex is important: in functional disease, as in health, the flexor response is the rule; in organic disease involving the pyramidal tract an extensor response is almost invariable. In certain cases neurasthenia approaches very closely to insanity. Sexual neurasthenia is but a shade removed from sexual hypochondriasis.

On the Centralization of Medical Education by the University of London. By Dr. A. D. Waller.

Some Remarks on the Inheritance of Acquired Immunity. By G. Ogilvie, M. B.

Note on the Results Obtained by Antityphoid Inoculations in Egypt and Cyprus during the Year 1900. By Dr. A. E. Wright.—The author gives the following table, showing the incidence of typhoid fever and the mortality from the disease for the year 1900 in the inoculated and uninoculated among the British troops in Egypt and Cyprus:

	Average Annual Strength.	Number of Cases of Typhoid.	Number of Deaths from Typhoid.	Percentage of Cases Calculated on Average Annual Strength.	Percentage of Deaths Calculated on Same Basis.
Uninoculated.	2,669	68	10	2.50	0.40
Inoculated.	720	1	1	0.14	0.14

The one case occurring among the inoculated was that of a patient admitted to hospital on the thirty-third day after inoculation. It would seem that the disease was in this case contracted before anything in the nature of protection had been established by the inoculation.

Case of Secondary Anæmia becoming Pernicious. By Dr. W. Edgecombe.—The author reports the case of a woman, aged thirty-eight years, who had suffered for twelve years from a secondary anæmia following smallpox but continued hæmorrhages from the nose. At the time

the first blood examination, in 1899, her symptoms had become those of pernicious anæmia, the red corpuscles being below half a million to the cubic millimetre, and the hæmoglobin index two and a half times normal. She could not take arsenic, but improved rapidly upon oxygen and an organic preparation of iron, and four months later examination showed her blood to be almost normal. She then gradually failed and died about a year and a half later. A table of the results of the numerous blood examinations is given, and shows the following points of interest: (1) The hæmoglobin fell to eight per cent. just before death; (2) the high color, or hæmoglobin index; (3) the preponderance of megaloblasts over normoblasts among the nucleated red cells; (4) the leucocytes were usually below the normal in number, the lymphocytes being relatively in excess.

The case clearly shows the possibility of chronic secondary anæmia passing into the pernicious form.

The Treatment of Two Cases of Nerve Leprosy in which Recovery Took Place. By Dr. G. Thin.—The author puts on record the outlines of two cases of nerve leprosy in which the credit of the cure must, apparently, be chiefly attributed to the action of drugs. In the first case chaulmoogra oil was prescribed both internally (in twenty-one-drop doses) and externally. In the second case pyrogallic-acid ointment was applied locally and turpentine oil, in drachm doses, given internally. For a number of years both patients have led active, useful lives, enjoying excellent health.

An Operation on the Subjects of Exophthalmic Goitre. By J. D. Harris, M. R. C. S.—The author reports the case of a patient suffering from well-marked Graves's disease, who was obliged to undergo amputation of the breast for cystic degeneration. She failed steadily after the operation, and died at the end of sixty-eight hours. The condition of the heart was from the first the most difficult; beating irregularly at great speed.

A Case of Descending Landry's Paralysis in a Child. By L. A. Rowden, M. B.—In the case here reported the diagnosis of Landry's paralysis of a descending form was made from (1) progressive, symmetrical, motor paralysis, affecting first the muscles of the neck—the "stiff-neck" complained of—then the arms, forearms, chest, legs, etc.; (2) sensation did not seem at all disturbed until a few hours before death, and even then only slightly; (3) absence of rigidity, twitching, pain or spasm; (4) mental functions unimpaired; no loss of control over the emunctories.

Two Cases of Severe Frontal Herpes. By C. Higgins, F. R. C. S.

An Unusual Symptom in Secondary Syphilis. By A. S. Skirving, F. R. C. S.—The author has observed several cases of secondary syphilis in which itchiness of the fauces has been present. It is a definite itchiness, in every way comparable to the ordinary feeling experienced in the skin, and accompanied by a similar desire for counterirritation by scratching. The occurrence of itchiness in syphilitic affections of the mucous membrane is the more remarkable, since, with the exception of small papular syphilides, specific cutaneous eruptions seldom itch much, often indeed not at all.

Whooping-cough Cured by Irrigation of the Nares. By E. M. Payne, M. B.—The author reports a case of whooping-cough, occurring in a boy aged nine years, in which the nose was irrigated with a one to forty carbolic lotion three times a day. The cure was complete in about a week from the time treatment was begun.

Münchener medicinische Wochenschrift, April 16, 1901.

Meningitis Serosa Acuta. By Dr. J. Hegener.

Treatment of Intestinal Tuberculosis. By Dr. Edwin Klebs.—(*Continued article.*)

Fermentation Processes. By Dr. Carl Oppenheimer.

Treatment of Rhachitis with Adrenal Extract.—Dr. Max Höningsberger found that rhachitic children placed under this treatment thrived very well. The general condition improved at once, or very soon, and while, in the majority of instances, the principal symptoms were favorably influenced, this result was not uniform. He concludes from his observations that suprarenal extract is not a specific in rhachitis.

Addison's Disease. By Dr. L. Huismans.

Gastric Lavage in Children.—Dr. Ignatz Steinhardt says that gastric lavage is easily practicable in children in private practice, even in nursing infants, and is rarely productive of harm. It is especially indicated in the acute digestive disturbances in little children when the usual remedies do not succeed in stopping the vomiting. It is almost universally followed by a rapid improvement.

Deutsche Medizinal-Zeitung, April 18, 1901.

Use of Röntgen Rays in Medicine.—Dr. Immelmann says that the conformation of the œsophagus can be determined by the Röntgen ray if the organ is filled with shot or a sound. It is not always possible to diagnose renal or vesical calculi, but this may be a development of the future. Arthritis deformans, gout, and rheumatism lend themselves well to detection by the x-rays. Therapeutically, especially in lupus, the rays have a distinct field of usefulness. The author mentions in detail the various injuries that may be detected by means of the Röntgen rays.

Prophylaxis of Gonorrhœa.—Dr. Ernst R. W. Frank describes a simple device of his own invention for the injection, after a suspicious intercourse, of a solution of twenty-per-cent. protargol in bichloride of mercury (1 to 2,000). He finds this an almost certain prophylactic against gonorrhœal infection.

Wiener klinische Wochenschrift, April 11, 1901.

Toxicity of Alcohol in Certain Nervous and Mental Diseases.—Professor Wagner von Jauregg draws attention to the curative influence of alcohol when it is given to patients suffering from alcoholic delirium. He accounts for this by assuming it to be an antidote for the toxins developed from the excessive use of alcohol, although the alcohol itself is not the direct toxic agent. In other nervous and mental affections it acts as a poison, possibly, the author thinks, from the fact that the liver, which is injured by alcoholic drinks, allows certain toxins to pass into the general circulation which evoke the symptoms of intoxication or poisoning.

Alcohol and Delirium. By Dr. Joseph A. Hirschl.—A statistical paper.

Local Use of Carbonic Acid in Menstrual Disorders.—Dr. Gustav Loimann recommends carbonic-acid baths and douches of the gas in dysmenorrhœa, amenorrhœa, oligomenorrhœa, chronic metritis, and cervical erosion. It must not be employed during pregnancy for fear of bringing on an abortion.

Centralblatt für Chirurgie, April 20, 1901.

Value of Aluminium Bronze Wire in Surgery.—Dr. Rudolf Pichler writes from Mikulicz's clinic that suture

material of aluminium bronze is easily sterilized, and that colonies of bacteria found in the neighborhood of these sutures are less virulent than those found about other suture materials. It is especially valuable in areas of the body which are not easily cleaned, such as the perineum, the scrotum, the inguinal region, and the lips. It is especially useful, too, when the skin is tightly stretched and when the sutures must remain in place for weeks at a time.

April 27, 1901.

Atropine before Ether Anæsthesia.—Dr. Ludwig Braun takes issue with Dr. Reinhard and affirms that atropine is not necessary before the administration of ether to prevent accumulation of mucus in the respiratory tract. Pure ether and a good mask will accomplish the same purpose. Atropine is not always, he adds, a harmless drug.

Gazette hebdomadaire de médecine et de chirurgie, April 21 and 25, 1901.

Chorea Treated by Cacodylate of Sodium.—M. Lanais reports five cases of Sydenham's chorea treated by the subcutaneous injection of the cacodylate of sodium. He gives three tenths of a grain for a period of fifteen days, then omits the drug for three or four days, and repeats the dose for an equal length of time. A cure was effected in all the cases reported.

Emotional Icterus. By M. Debove.

Indépendance médicale, April 24, 1901.

Chlorosis. By M. Hayem.—A clinical lecture in which the diagnosis between chlorosis and tuberculosis is pointed out.

Presse médicale, April 13, 1901.

Pyonephrosis of Typhoid Origin. Dr. M. Garnier and Dr. Lardinois formulate the following conclusions from their investigations: Typhoid fever can give rise to renal suppurations affecting the form of pyonephroses open or concealed. The first signs often appear even in the course of the fever, but it is only after the establishment of convalescence that the diagnosis can be established. The diagnosis is to be founded on the existence of pains in the lumbar region, the establishment of tumefaction, more or less considerable, of the kidney, and, in certain cases, in intermittent pyuria. The treatment is, before all, surgical; intervention, as early as possible, by nephrotomy, may suffice, and may give with the least risk excellent results; but nephrectomy will often be secondarily indicated when the abscesses are numerous, badly drained, and if there is good ground for considering the other kidney intact.

April 17, 1901.

So-called Glandular Fever.—M. Marcel Labbé believes this peculiar condition to be due to bacillary invasion of a gland or glands. He thinks that the germs, according to the law worked out by him and Bezançon, wander from one gland to another, as a germ which has lived and thrived in one form of tissue has a tendency to localize anew in similar tissue. He thinks, therefore, that the title "glandular fever" should rather be replaced by the name "non-specific, acute infectious hypertrophic adenitis," as this corresponds to the clinical facts, to the particular condition of the glands as they are found in the disease, and to the special properties acquired by the causative germ. In the matter of prophylaxis, antisepsis

of the nasal, buccal, and pharyngeal cavities is to be observed.

Technics of Shortening the Round Ligaments in the Inguinal Canal.—M. E. Juvara describes his method. He first cuts down upon the inguinal canal, opens it, seeks for and dissects out the round ligament. The ligament is drawn up and deep sutures of catgut are passed through it in the same manner as in the Bassini operation for hernia. Before the canal is closed, the round ligament is split into two portions, and these portions are made to traverse the superior and oblique muscles, the transversalis and the tendon of the superior oblique. The ends are then tied together, and the entire wound is closed.

April 20, 1901.

Surgery of Deafness. By M. Georges Laurens.

Ureterovesical and Pyelovesical Reflexes.—M. Bazin says that bimanual palpation of the kidneys does not always elicit, in suppurating pyelitis, a painful area. But when pressure is made upon the anterior abdominal wall a few inches from the median line, a painful radiation toward the bladder is elicited, which may be called a pyelocystic reflex. It is uncommon. The ureterocystic reflex is much more common and is more easily elicited in women than in men. On vaginal examination, the bladder being empty, palpation reveals a tender spot and causes a desire to urinate. This marks the junction of the ureter and the bladder. When but one kidney is affected, this painful area is felt on the affected side; it is present on both sides when both kidneys are involved. When the bladder only is diseased, its neck is the only painful portion. He describes a test, which he calls Bouchard's sign, for distinguishing pus from the kidney and from the bladder. To the suspected urine, Fehling's solution is added drop by drop until the fluid becomes somewhat gelatinous. The tube is then violently shaken. If the pus comes from the bladder, nothing is noted; if it comes from the kidney, globules of gas can be seen imprisoned in the fluid, especially toward the bottom. Also, if the pus is of vesical origin, it will sink to the bottom of the container, while, if it is renal in origin, it will rise to the surface and form a layer like saliva.

Lyon médical, April 14 and 21, 1901.

Abnormal Forms of Pyloric Stenosis. By M. Bouveret.

Formation and Evolution of Fat in the Normal and Pathological States. By M. E. Dufourt. (*Continued article.*)

Biochemical Rôle of the Prostate.—M. J. Eraud, in an elaborate study of the functions of the prostate gland concludes that a modification of the prostatic fluid from alkaline to acid can contribute in a certain measure to create sterility or to modify profoundly the vitality and structure of the spermatozooids which cannot live in an alkaline medium. Further, it possesses a certain biochemical action, which calls forth the secretion of a powerful special poison that acts particularly upon the serous portions of the body.

Riforma medica, March 22, 23, and 25, 1901.

A Case of Cardiac Suture. By Dr. Francesco Lantaria.—Of twenty-three reported cases of wounds of the heart which had been treated by suture, eight recovered. The author's patient was a lad, nineteen years old, who had received a penetrating wound about four centimeters in length in the fifth intercostal space at the parasternal

line. The author saw the patient half an hour after the injury had been inflicted. After disinfecting the wound, a horizontal incision curving slightly upward was made from the wound to the anterior axillary line. The third, fourth, fifth, and sixth ribs were severed by means of bone forceps, and a flap of ribs and intercostal tissue lined with pleura was reflected to the side. A wound in the pericardium was found and enlarged laterally, the finger introduced, the heart brought upward and forward, and the wound in the anterior wall of the right ventricle exposed and immediately compressed by the fingers of an assistant. The heart continued to beat during the entire operation. After the wound had been sutured the toilet of the pericardium and pleura was made, the pericardial wound sutured, except at one end where a gauze drain was inserted, the flap replaced and sutured into position, leaving space for the pericardial drain and for another drain from the pleura. At no time were there any signs of syncope, and the anæsthesia progressed well throughout. The entire operation lasted half an hour. The patient did well for a few hours after the operation, but then the circulation gave out in spite of stimulants, and he died on the following morning.

March 26 and 27, 1901.

On the Trypsin-forming Function of the Spleen.

By Dr. T. Silvestri.—Experimental researches conducted by the author, with a view of determining the rôle of the spleen in the formation of trypsin, were the basis of the following conclusions: The existence of a secretion of the spleen which contains trypsin cannot be affirmed. The results of the author's researches indicate that the spleen exercises a mechanical function in digestion.

April 1, 1901.

On a Form of Chorea Complicating Erysipelas.

By Dr. Luigi Fornaca.—Lumbar puncture has been performed for diagnostic purposes, in Bozzolo's clinic in Turin, since April, 1898. During the past year the author had occasion to perform lumbar puncture three times in cases of chorea. The first patient was a girl thirteen years of age, in whom the puncture was executed on the fifth day of the disease, which had developed acutely, without any fever. The second patient was a girl aged ten years, in whom the choreic phenomena appeared simultaneously with an acute otitis, followed by rupture of the membrane and a copious flow of pus. In this patient, a puncture was made on the first day after admission and again a few days later. The liquid obtained from the spinal canal of both these patients was clear, abundant, and sterile when grown on ordinary media. Inoculations into guinea pigs resulted negatively. In the third case the patient was a girl aged fourteen years, who was admitted to the clinic for erysipelas of the face, which disappeared under treatment in two weeks. Two months later she had another attack of acial erysipelas. On the third day after admission, horeiform movements were noticed, and three days later lumbar puncture was performed. The fluid was clear and cultures were prepared on various media. In the meanwhile, cultures were also prepared from the patient's blood and from her urine. The cultures of spinal fluid showed the presence of a streptococcus. Injections of the pure culture into the cranium of rabbits were followed by fever and paralysis of the limbs, which gradually disappeared. Subcutaneous injections in guinea pigs were negative. Streptococci have been found *post-mortem*, by Eberth and others, in chorea, but the special

interest in the present account lies in the fact that this germ was for the first time demonstrated during life in cases of chorea. Lumbar puncture should be more extensively employed in diagnosis.

April 2, 1901.

The Bactericidal Action of Saturated Solutions of Sodium Chloride. By Dr. Francesco Testi.—The author's conclusions are as follows: Saturated salt solutions possess a certain degree of bactericidal power on various pathogenic germs. This action is increased greatly by an elevated temperature. In their order of resistance to salt solutions the following germs may be named: The cholera bacillus, the bacillus of Finkler, the bacilli of typhoid fever, diphtheria and glanders, and the *Staphylococcus pyogenes aureus*. These data refer to a temperature of 36° C.; at lower temperatures the resistance of these germs is much greater. The spores of the bacillus of anthrax lose their vitality in a day after exposure to salt solution at 36° C. On the other hand, the *Bacillus subtilis* resists this treatment. The anthrax bacillus is not affected by the solution in any way.

Klinitchesky Journal, January, 1901.

Catheter Fever. By Dr. C. Posner.—The author discusses the ætiology of catheter fever and emphasizes the fact that, in addition to infection with germs that penetrate into the mucous membrane of the urethra through lesions caused by the introduction of instruments, catheter fever may also be due to intoxication as the result of the absorption of toxines generated by germs in the urinary tract. The absorption of these toxines may take place without any lesion of the mucous membrane, as urethral fever has occurred without the introduction of instruments into the canal. The power of absorption is, however, fortunately quite limited. No absorption of any consequence takes place in the anterior urethra; the posterior portion of the canal can only absorb toxines through the medium of the prostate; the bladder cannot absorb toxines so long as its epithelium is whole. On the other hand, the pelvis of the kidney, and the kidney itself, are ready surfaces for absorption of bacterial poisons.

On the Action of Sodium Cinnamate in Tuberculosis.

By Dr. A. P. Braunstein.—Experimental and clinical evidence collected by the author serves as a basis for the following conclusions: Sodium cinnamate has no influence whatever upon experimental general tuberculosis in guinea pigs. The drug has no effect upon local tuberculosis (ulcers). The virulence of tubercle bacilli found in the sputum of tuberculous patients remains unchanged under the influence of injections of sodium cinnamate subcutaneously. The drug diminishes the amount of sputum expectorated, and converts purulent sputum into mucous expectoration, but does not diminish the number of tubercle bacilli in the sputum.

A Case of Hepatic Neuralgia Simulating Cholelithiasis. By Dr. N. N. Michailoff.—Fuerbringer described, in 1891, under the designation of hepatic neuralgia a symptom-complex resembling biliary colic, but entirely independent of gall-stones. This syndrome occurs most frequently in neurotic women, especially during the menstrual periods or in the presence of scanty or disordered menstruation. The chief symptom is intense pain, leading sometimes to collapse. The diagnosis is the more difficult because jaundice may accompany this condition, probably as the result of spasmodic contraction of the biliary capillaries. The ætiology is obscure, and the

affection is for the present classed as a neurosis. The author reports a case of this syndrome. The patient was a girl, aged nineteen years, who presented a clear picture of gall-stones. An exploratory laparotomy was performed, but nothing abnormal was found. The gall-bladder was, however, sutured into the wound in order to open it if occasion should require later. The pains disappeared immediately and completely after the operation. The author does not attribute any real effect to the cystopexy.

Vratch, March 17 (March 29, New Style), 1901.

On the Physiological Action of the Alkaloid *Johimbin* and on its Significance in the Treatment of Impotence. By Dr. N. P. Kravkoff.—*Johimbin* is obtained from the bark of the *Jambehu* tree, *habitat*, the German African colonies, probably a member of the order *Rubiaceæ*. It was first obtained by Spiegel, and simultaneously by Thoms in 1899, and occurs in silky, crystalline needles, easily soluble in alcohol, ether, etc., but insoluble in water. Various salts of this alkaloid have been prepared, but the hydrochloride is used in preference to the others. The natives use an infusion of the bark as an aphrodisiac, and Oberwarth has shown that the alkaloid possesses aphrodisiac properties. Mendel and Lowy have tested the drug clinically and found it to be an efficient and harmless sexual stimulant. A gramme costs thirty-six marks (\$9), and from five to ten drops of the one-per-cent. solution of the hydrochloride are given three times daily. Tablets containing five milligrammes each are also for sale in Germany. The author has conducted a series of experiments on animals with a view to determining the action of this alkaloid. (*To be continued.*)

On the Question of the Alkalinity of the Blood. By V. F. Orloffsky.—The author has found that Engel's alkalimeter gives figures indicating the percentage of alkalinity in the blood which exceed the actual amount by 106 milligrammes with litmus as indicator, and by 119 milligrammes with laemoid (a compound of resorcin and sodium nitrite) as indicator. The alkalinity of the blood in health is represented by from 240 to 267 milligrammes of NaOH to one hundred cubic centimetres of blood with litmus as indicator and from 269 to 299 milligrammes with laemoid. In some diseases the alkalinity of the blood is directly proportional to the number of red cells. The determination of the alkalinity of the blood alone in diseased conditions cannot give a correct conception of the causes of its deviation from the normal. The presence of a self-intoxication with acids can only be affirmed when the number of red cells is normal, while the alkalinity is greatly diminished, or when the diminution of alkalinity is much greater than the diminution in the number of red corpuscles. The latter conditions have thus far been observed by the author only in severe forms of saccharine diabetes and in cancerous cachexia. Small (259 cubic centimetres) warm alkaline enemas raise the alkalinity of the blood to a greater extent than the ingestion of alkalies in both health and disease, but this rise in alkalinity is in either case short-lived. The author announces the publication of further researches on the subject in the near future.

Some Difficulties in the Combat with Diphtheria. By Dr. G. N. Gabritchevsky.—The chief difficulty is the fact that diphtheria bacilli may persist in the throat and nose for weeks, or even months, after complete recovery, and may be present in persons who have never suffered from any symptoms of the disease. The author calls at-

tention to the fact that in these chronic carriers of diphtheria there are usually some pathologic changes in the nasal or pharyngeal cavity, such as adenoids, hypertrophic tonsils, rhinitis, syphilitic lesions, etc. He has also found that diphtheria bacilli persist more tenaciously in anæmic and weakened children than in healthy ones. The conclusion is that patients should be kept under treatment until they are perfectly well after an attack of diphtheria.

The author also recommends what he calls *relative isolation* for chronic carriers of the infection; namely, that the patient be left to live with his family, but that all precautions against the spread of the contagion be rigidly observed. Thus the mouth and throat should be kept clean and disinfected; handkerchiefs should be sterilized after being used, and the expectoration should be collected in special vessels, etc. A special set of dishes should be used, and close contact with other persons, especially children, should be avoided.

On Postpartum Metrophlebitis. By Dr. B. A. Lieboff.

Proceedings of Societies.

KINGS COUNTY MEDICAL ASSOCIATION.

Meeting of December 11, 1900.

The President, Dr. H. ARROWSMITH, in the Chair.

The Specific Treatment of Acute Dysentery.—Dr. W. J. CRUIKSHANK presented a paper with this title (see page 403).

Dr. IRA VAN GIESON said that, though he was not familiar with the details of the clinical study of the disease, he might be permitted to say a few words about the relation of clinical study to other departments of medicine in general, because sometimes when we saw a department of science from a distance and were not wrapped up in its details we could appreciate its limitations better than if we were in the midst of its specific and detailed study.

There seemed to be a curious perversion of the understanding of the true science of medicine latterly in that, through the spread of laboratories, there had arisen a great competition in the study of bacteriology and pathological anatomy, as though they were to be regarded as the highest attainment in medical science, and the study of symptoms was of secondary importance. You notice this particularly among the undergraduates. When they wish to study the science of medicine, they desire to enter the laboratory, as though the study of clinical phenomena was not the highest study of medical science. The paper just presented was one of those rare and ideal presentations of medical science which were a triumph to the practitioner and proved what the speaker had just said. The living phenomena—the phenomena which the patient showed—contained the very heart of the problem. The really very great discoveries in medicine had been made by the practitioner, because he had been nearest the active phenomena. Those who worked in laboratories and studied dead tissues were, after all, working in a field that was of secondary value. It brought up the remark of Oliver Wendell Holmes, that the student of pathological anatomy was to be likened to the man who looked at what was left of the fireworks the day after the show. Pathology was a study of symptoms. The reflective clinician was the truly great scientist in medicine; his department really, it seemed to the

speaker, contained the opportunity for getting at the greatest truths in all the departments of medicine. Sometimes it actually seemed, from the growth and spread of laboratory literature, that this had been lost sight of, and that the true science of medicine consisted in looking at dead tissues and in the work of the test-tube or of culture media. The speaker did not wish to be understood as disparaging such work, or giving the impression that it was not desirable and, indeed, essential.

He had taken the liberty of making this introduction, because he wished to emphasize by it the character of the paper presented. This contribution brought out a great discovery, one made out by the study of living phenomena, the discovery of symptoms, the triumph of the practitioner. It was the same kind of work that Jenner had done, that Lord Lister had done, that Alonzo Clark had done in the treating of peritonitis. Of course, the laboratory work gave us a means of verifying certain theories and notions gained from clinical study. The treatment of hydrophobia and the treatment of diphtheria, it was true, had been evolved from the laboratory, and this had been essential because they had required extensive study in bacteriology and extensive animal experimentation. Nothing would be more fallacious than for us to overestimate the value of laboratory work in medical science. The paper of the evening was a striking demonstration of this.

The speaker had been struck by the scientific and logical character of the paper and by the method which had been used to get at the discovery and verify its truth. The author had brought his arguments forward in such a way as to convince us of the value of this great medical discovery, and give us all an opportunity to put it to practical use. Some men were speculative and could not apply their ideas in practical life; others took a forward position in practical affairs, but could not speculate or rise above the mere survey of facts. The paper under discussion seemed to him to be well balanced, for it gave us theory combined with practice. It was truly rare for us to hear papers which combined both theory and practice. The speaker did not hesitate to eulogize this paper, because it was a great achievement to place within human control a disease which made such ravages. In 1897 90,000 persons were afflicted with dysentery in Japan, and out of this number 22,000 died. It was surely a great achievement to place in our hands a therapeutic agent for such a disease, with an explanation of how it acted and why it should be efficacious.

A paper on rational therapeutics was a most difficult one to write. One working in a laboratory with a certain amount of diligence might prepare papers which were of interest because of their technical value or as a mere catalogue of facts, but they were found utterly useless to medical men in their practice. A paper on rational therapeutics implied great comprehensiveness and a knowledge of many departments of medicine; it required a knowledge of bacteriology and a knowledge of the disease process and of the succession of phenomena seen by the clinician. One might obtain eminence in any one of these departments, but to combine them all to practical advantage was truly an ideal effort. Such a paper, when written, was not one of transient interest. After the meeting of the Congress of American Physicians and Surgeons in Washington last spring, our great American Nestor in medicine had taken the floor and said: "Gentlemen, I have heard many brilliant papers on many departments in medicine; I have heard of many brilliant discoveries in pathological anatomy, yet I have heard not

a single paper which has given us any help in the treatment of our patients." Had the paper presented this evening been read at that meeting Dr. S. Weir Mitchell would not have felt compelled to make this criticism.

The speaker thought it would be presumptuous on his part to go into the detailed consideration of the paper. The story of the ætiology in general terms was comparatively simple and straightforward. Some exciting agent entered the alimentary canal and lodged in one of the coats of the intestine, and the first natural defense exhibited by the body was to drench that agent by an outpouring of serum, a supersecretion of the tissues. This was full of significance. There was growing up a school of medicine which dealt largely with molecular motion in the tissues, but no amount of knowledge of the motion of molecules in the tissues would enable one to tell what was the purpose of life. The purpose and significance of that defense of the body against the exciting cause was to get rid of it and enable the body to survive the contest. That had been the pith of one portion of the evening's paper. The author had protested against treatment which was eminently contradictory to the natural defenses of the body, and, on the other hand, gave a drug which did that. Certainly this seemed to be rational therapeutics. That other people had used this did not in the least detract from the real value of the paper.

The speaker had had the privilege of knowing the evolution of the author's working out of this idea. Some eighteen months before, in a conversation with him, allusion had been made to the case which he had now said he had treated some years ago. When the natural defenses of the body were so plain, why should we do our best to defeat this effort by locking up the bowel with opium and covering over the surface of the bowel with bismuth? The discovery proclaimed in this paper had been made independently by careful and thoughtful clinical observation. Having done this, the author had looked around to learn what others had done in this direction. The value of a fact did not lie in the fact itself any more than the value of a dollar lay in the dollar itself. The value of a dollar, like the value of a fact, lay in its relations to other things, and to appreciate this value we must speculate. The paper had admirably combined both theory and fact.

Dr. JACOB FUHS said that, after such interesting remarks as had been made by the previous speakers there was very little left for him to say. A paper which brought forth a rational method of treatment was certainly a valuable one. That the treatment was a rational one was shown, not only by the results attained, but by its applicability to other infectious diseases. We saw that Nature's method of treating the disease was eliminative. Even in typhoid fever the diarrhœa must be looked upon, not as an evidence of an additional disease process, but as evidence of the effort to relieve the intoxication. The diarrhœa had for this reason long been known as a toxic diarrhœa. We saw the same thing in other diseases—the so-called critical diarrhœas. The speaker thought, therefore, it was rational to treat an infectious disease, such as dysentery, by the method similar to that employed in other infectious diseases. Why we should have come to use the strange methods of treating dysentery which had been in vogue in the past was hard to understand. The diarrhœa of typhoid fever was rarely painful, and there was no need for narcotics, but in dysentery there was a strong temptation to treat the symptoms, pain and tenesmus. This probably explained why narcotics had been so generally administered. It had been customary in the past to counteract this bad

effect of narcotics by giving castor oil. The use of castor oil and opium combined had constituted the treatment in vogue in the early years of the speaker's practice. Sometimes this had been varied by using some astringent or by employing the sulphuric-acid treatment. He had found this latter treatment so useful that he had gradually reduced the morphine treatment to the minimum. Lately he had had an opportunity of testing the sulphate of magnesium treatment in a limited way, and so far as his experience went he could most heartily endorse it.

Letters to the Editor.

HÆMOSTATIC TAMPONS.

PASADENA, CAL., April 27, 1901.

To the Editor of the *New York Medical Journal*:

SIR: In your issue of April 20th Dr. P. M. Miller writes, on page 698, that he used *absorbent* cotton for a vaginal tampon in case of postpartum hæmorrhage. For the reason that a hæmorrhage passes freely through absorbent cotton I consider it unfit for this purpose, and I have seen serious results follow in one case where the surgeon assured the nurse that all was safe with the tampon in place.

EDWIN R. CHADBOURNE, M. D.

Book Notices.

An Atlas of the Bacteria Pathogenic in Man, with Descriptions of their Morphology and Modes of Microscopic Examination. By SAMUEL G. SHATTOCK, F. R. C. S., Joint Lecturer on Pathology and Bacteriology, St. Thomas's Medical School, London, etc. With an Introductory Chapter on Bacteriology: Its Practical Value to the General Practitioner. By W. WAYNE BABCOCK, M. D., Pathologist to the Kensington Hospital for Women, etc. Sixteen Full-page Colored Plates. New York: E. B. Treat & Company, 1901. Pp. 7 to 82.

THIS is a reprint from the *International Medical Annual*. While the plates of the bacteria are beautifully executed and the limited text is above reproach, an atlas of this kind must necessarily be compared with the standard work, Fränkel's, and in this comparison it suffers severely. Some of the plates are more clearly elucidated than others. The work is attractive and ought to be of value to teaching students a discriminating knowledge of the various bacteria pathogenic to men.

The Essentials of Practical Bacteriology. An Elementary Laboratory Book for Students and Practitioners. By H. J. CURTIS, B. S. and M. D. Lond., F. R. C. S., Late Surgical Registrar, University College Hospital, etc. New York and Bombay: Longmans, Green & Company, 1900. Pp. xvi-291.

THE author of this excellent manual enters no speculative field of bacteriology, such as immunity and the production of toxins and alexines. He has confined his work exclusively to the laboratory side of the subject. He first gives directions for the preparation of culture media, then treats of methods of staining and cultivation, and considers next the examination of bacteria. In the succeeding division the non-pathogenic and the pathogenic bacteria, also the protozoa, are systematically considered. The author also describes Plimmer's cultivation of the protozoon of cancer and expresses the hope

that some good may come of such researches. A chapter on the bacteriological examination of soil, water, air, and milk and one on testing disinfectants and antiseptics are added. An appendix on the fixing and staining of histological objects is also presented.

The illustrations are mainly new, although some are borrowed from other works on bacteriology, while some are in colors. As a teaching book for students, or as a work of reference for one who does occasional bacteriological work, the book is admirable. It is not a textbook, but it is an admirable laboratory guide.

Obstetric Clinic. By DENSLOW LEWIS, Ph. C., M. D., Professor of Gynæcology in the Chicago Policlinic, etc. A Series of Clinical Lectures on Practical Obstetrics delivered to Students and Practitioners in Cook County Hospital, Chicago, together with Remarks on Criminal Abortion, Infanticide, Illegitimacy, the Restriction of Venereal Diseases, the Regulation of Prostitution, and other Medicosociologic Subjects. Chicago: E. H. Colegrove, 1900. Pp. viii-652. [Price, \$3.00.]

DR. LEWIS'S book is a collection of clinical lectures delivered at various times, and consequently the lectures bear little logical relation to each other. They are concise and cover almost the entire field of obstetrical physiology and pathology. The author branches off interestingly into the relations of syphilis and prostitution to the community. As to the latter, he takes the sane and modern Anglo-Saxon view that regulation of the social vice is impossible and impracticable, and he points out the feasible plan of teaching continence to man. He advocates, too, the isolation and care of women venereally infected, regarding the spread of gonorrhœa and syphilis as the worst features of prostitution.

In his views on obstetric subjects, Dr. Lewis does not depart from the accepted teachings. In a few details his therapeutic measures are different from those of others, but these are insignificant. The lectures form very interesting reading as a *résumé* of modern obstetric didactics. They are sound and convincing.

We trust that if another edition of the work should be printed, the author will see to it that a better quality of paper is employed.

Flesh Foods, with Methods for their Chemical, Microscopical, and Bacteriological Examination. A Practical Hand-book for Medical Men, Analysts, Inspectors, and others. By C. AINSWORTH MITCHELL, B. A. (Oxon.), F. I. C., F. C. S., Member of Council, Society of Public Analysts. With Illustrations and a Colored Plate. London: Charles Griffin & Company. Philadelphia: J. B. Lippincott Company, 1900. Pp. xv-336.

THIS work is one of more interest to the physiological chemist than to the practising physician. It deals with the methods of examination of the flesh of birds and domestic and wild quadrupeds, the means of preservation of flesh, the detection of adulterations, the poisons developed in meats, and methods of bacteriological examination. While the book is undoubtedly a thorough exposition of its subject, its theme does not warrant a more extended review in these columns.

The Medical News Pocket Formulary for 1901. By E. QUIN THORNTON, M. D., Demonstrator of Therapeutics, Pharmacy, and Materia Medica in the Jefferson Medical College, Philadelphia. Third Edition, Re-

vised and Enlarged. Philadelphia and New York: Lea Brothers & Co., 1901. [Price, \$1.50.]

THIS edition has been brought fairly well up to date by the inclusion of many of the more recent additions to the materia medica. The prescriptions are arranged alphabetically under the headings of the various diseases, and among those given under hay fever we notice formulas for tablets and solutions of suprarenal extract. We assume that the usefulness of the salts of glycerophosphoric acid is not recognized by the author, since they receive no mention under any disease heading. The book is bound in leather and is of the convenient size and shape of a wallet for carrying in the pocket. Its usefulness would be increased, we think, by an index of the drugs named in the formulas. Greater uniformity in the names of drugs would also make for its improvement.

BOOKS, ETC., RECEIVED.

Principles of Surgery. By N. Senn, M. D., Ph. D., LL. D., Professor of Surgery in Rush Medical College, etc. Third Edition, thoroughly Revised. With 230 Wood Engravings, Half-tones, and Colored Illustrations. Philadelphia and Chicago: F. A. Davis Company, 1901. Pp. xiv-699. [Price, \$4.50.]

Manual of Diseases of the Ear, including those of the Nose and Throat in Relation to the Ear. For the Use of Students and Practitioners of Medicine. By Thomas Barr, M. D., Lecturer on Diseases of the Ear, Glasgow University, etc. Third Edition, Revised and partially Rewritten. With 236 Illustrations. Glasgow: James Maclehose & Sons, 1901. Pp. xxiii-429. [Price, \$4.]

Uterine Fibromyomata: Their Pathology, Diagnosis, and Treatment. By E. Stanmore Bishop, F. R. C. S. Eng., President of the Manchester Clinical Society, etc. With 49 Illustrations. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. xii-13 to 323. [Price, \$3.50.]

A System of Physiologic Therapeutics. A Practical Exposition of the Methods, other than Drug-giving, Useful in the Treatment of the Sick. Edited by Solomon Solis-Cohen, A. M., M. D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic, etc. Volume I. Electrotherapy. By George W. Jacoby, M. D., Consulting Neurologist to the German Hospital, New York, etc. In Two Books. Book I. Electrophysics—Apparatus required for the Therapeutic and Diagnostic Use of Electricity. With 163 Illustrations. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. xxii-17 to 242.

Select Methods in Food Analysis. By Henry Leffmann, A. M., M. D., Professor of Chemistry and Toxicology in the Woman's Medical College of Pennsylvania, etc., and William Beam, A. M., M. D., formerly Chief Chemist for the Baltimore and Ohio Railroad. With 53 Illustrations in the Text, 4 Full-page Plates, and many Tables. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. viii-9 to 383. [Price, \$2.50.]

Aphorisms, Definitions, Reflections, and Paradoxes, Medical, Surgical, and Dietetic. By A. Rabagliati, M. A., M. D., F. R. C. S. Ed., Consulting Surgeon, Bradford Children's Hospital, etc. New York: William Wood & Company, 1901. Pp. xiv-291.

Die periodischen Geistesstörungen. Eine klinische Studie. Von Dr. Alexander Pilez, Assistant der k. k. I. psychiatrischen Universitätsklinik in Wien. Mit 57 Curven im Text. Jena: Gustav Fischer, 1901. Pp. vi-210.

Catalogue of the Library of the Pharmaceutical Society of Great Britain, in London. Eighth Edition. Compiled by John William Knapman, Librarian.

New Inventions, etc.

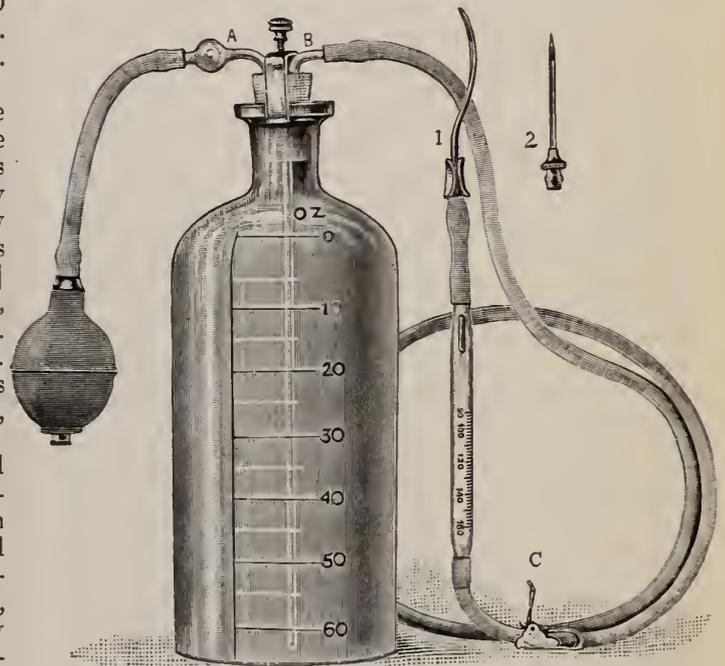

A NEW INFUSION APPARATUS.

By GEORGE RYERSON FOWLER, M. D.,

BROOKLYN, N. Y.

A GOOD infusion apparatus should possess the following qualities: It should be cleanly, convenient, easily kept in order, and capable of being immersed in warm water in order to maintain the temperature of the contained infusion fluid as equable as possible. The temperature of the infusion fluid as it reaches the cannula should be known. Finally, the apparatus should be adapted for use in intracellular infusion.

I have endeavored to meet these requirements in the apparatus herewith figured. The bottle is graduated in

ounces. Through the rubber cork, which is secured by a simple clamp and screw device, two lengths of glass tubing are placed (A, B), the one reaching to the bottom of the bottle, the other terminating just within the bottle; in the course of the latter a bulb is blown in which a mass of cotton or lamb's wool is placed as an air-filter. To the short glass tube a rubber bulb is attached. To the long tube a length of rubber tubing is connected, and to the further extremity is attached a piece of glass tubing in the interior of which a thermometer is placed. Finally, a conveniently curved metal cannula (I) is connected with the latter by a short piece of rubber tubing.

The manner of emptying the apparatus is as follows: The bottle is filled with decinormal saline solution of the proper temperature and placed in a basin of water of a slightly higher temperature. Hot water is added to that in the basin from time to time, as required to maintain the temperature within the bottle. The infusion fluid is forced from the bottle by slow and steady strokes of the bulb, air being driven above the surface of the water, passing through the filter on its way to the bottle. As

much or as little pressure as may be desired may be made in this way, this being graduated according to the rapidity or otherwise of the infusion as required.

Miscellany.

Electricity in the Treatment of Diseases of the Genito-urinary Tract. Dr. W. H. Walling (*International Medical Magazine*, February) discusses the use of electricity in sexual weakness and impotence, catarrh of Cowper's glands, spermatorrhœa, enlarged prostate, varicocele, hydrocele, urethral stricture, gonorrhœa, and syphilis. In *sexual weakness and impotence*, the genito-spinal centre in the lumbar portion of the cord is either irritable or anæsthetic. The electrical treatment for all cases of loss of the genital functions, of whatever degree or from whatever cause, is the same, and consists of the galvanic and faradaic currents alternated at proper intervals with franklinic insulation and the breeze. The patient is seated upon a well-wetted pad connected with the anode of a high-tension, faradaic, secondary coil, and the spine and the nerves proceeding from the same tested with the cathode, using a current intensity plainly perceptible to the patient. Note all the conditions, whether anæsthetic or irritable. Anæsthetic areas are to receive the cathode in treatment and all irritable or painful portions the anode—whether the current used be galvanic or faradaic. Sittings may be given for fifteen minutes, three times a week, with the faradaic high-tension current for ten minutes, closing each sitting with five minutes' use of the galvanic current as indicated, with an intensity of from five to ten milliampères. The inguinal region should also receive attention in like manner. After a few weeks of such treatment the genitalia may be placed in a bowl of water and the current applied directly through them; or the patient may be placed on a table with one pad under the back and another to the genitals and either current given as desired. Where stimulation to the nerve centres as well as to the parts seems desirable, frequent changes of polarity may be made, but without shock. In some cases the faradaic brush may be used with good effect, applying it to the penis and the pubic region. The seat of the disability being, however, located in the nervous mechanism governing the parts, the genitospinal centre, as well as the whole central nervous system, should receive especial attention. Static insulation is of decided benefit in these cases, as well as the anodal breeze from a pointed wooden electrode applied to the whole spine and the back of the head. After a sufficient time has elapsed sparks may be drawn from anæsthetic areas if they still exist.

Catarrh of Cowper's Glands.—In addition to the foregoing, an insulated bougie connected with the galvanic anode should be kept moving (otherwise it is liable to stick) in the affected part of the urethra, with a current of from three to five milliampères, for from one to three minutes, and the process repeated daily or every other day. *Spermatorrhœa* should be treated as for impotence. *Enlarged prostate* calls for direct applications to the enlarged gland either by electrolysis with a mild galvanic current, or by cataphoric applications of a solution of potassium iodide by means of a hard-rubber catheter, perforated at the distal end with a number of small holes and carrying a metallic stem throughout its length. The instrument is introduced into the prostatic portion of the urethra, the end of the stem wound with absorbent cotton, dipped in four-per-cent. cocaine solu-

tion, inserted, and the parts rendered anæsthetic with the galvanic anode, ten milliampères for from five to ten minutes. The stem is then withdrawn and the cotton dipped in a thirty-grain-to-the-ounce solution of potassium iodide, and reinserted, the battery pole charged, and a *cathodal* current passed. The other pad may be on the abdomen or thigh. Treatment once a week. The enlargement may also be attacked *per rectum* by electrolysis, using one or two needles, as deemed best, but the urethral treatment is considered by the author to give better results. Anodal galvanization, three to five minutes with three to five milliampères, and keeping the instrument moving, is useful in irritable conditions of the prostatic urethra. The electrical treatment of *varicocele* consists in galvanic anodal applications by means of a suitable bifurcated electrode, with a current of from fifteen to twenty milliampères every other day, or a milder current every day for ten to fifteen minutes. The anodal current thus applied contracts the dilated vessels, promotes absorption of the hypertrophied portions, and imparts by its inherent qualities the necessary tone to the debilitated structures, with a consequent return to the normal. This method of treatment is absolutely safe, painless, and effective.

For *hydrocele*, electrolysis presents a perfectly safe, sanitary, and effective method of treatment. A suitably insulated trocar and cannula is introduced, and if the sac is very much distended by the contents, a portion may be withdrawn, the rest being left to act as an electrolyte. The instrument is then used as the cathode and a current of from twenty to thirty milliampères applied for twenty minutes. As a result of the action of the current on the sac, it may swell and be slightly painful for a few days; but this will rapidly subside, the whole contents become absorbed, and the tumor disappear. In some cases a repetition of the treatment may be necessary. **Stricture of the Urethra.**—First ascertain the size of bougie that will easily pass the stricture, select one two sizes larger (using what are known as "Neumann's sounds"), insert it up to the stricture, turn on from three to five milliampères of current and pass the bulb through the obstruction with *very* gentle pressure; then bring the instrument back through it in the same manner, and immediately and quickly withdraw the bulb from the canal. Treatment may be given once a week. Forbid the use of dilators or other appliances during the intervals of treatment. At the next sitting the instrument used as an electrode should pass the obstruction; if it does not, use it again. If it passes, use two sizes larger, and so on until the desired calibre has been attained. If the canal is very irritable, a four per cent. solution of cocaine may be injected before operating, but no other application will be required. Time and experience have fully substantiated the claims of this method of treatment to superiority over that by forcible dilatation or the urethrotome. In *gonorrhœa*, treatment should be instituted so soon as the disease first manifests itself. Taken in this early stage, it can be at once checked. After the patient has urinated, a suitable-sized copper bougie, insulated to within half an inch of the distal end (a Neumann's sound will answer) connected with the anode, is passed until it fully engages the prostatic urethra, the cathode being applied to the thigh; from five to eight milliampères of current are then turned on and the instrument slowly withdrawn and released at the meatus by a sudden movement. A green discoloration, the oxide of copper, will appear at the meatus, and its character should be explained to the patient. This chemical, liberated by the action of the current upon the metal in

connection with the salts present, acts as a powerful anti-septic and germicide, penetrating deeply into the surrounding tissues, thus reaching and destroying the gonococci. Treatment may be given every day for three or four days, or every other day, as may be deemed advisable. Some soothing injection may then be given, together with internal medication, if necessary, and the case practically dismissed. Gleet may be treated in the same manner, as may any irritable or hyperæsthetic condition of the urethra; the latter, however, receiving milder currents.

Syphilis.—The initial lesion in this disorder may be acted upon with a copper electrode (anode), and gummatous deposits, if accessible, are reducible by cataphoric applications of potassium iodide.

Medicine, of course, has its place in the treatment of all diseases and conditions that have been considered. The author never uses zinc sulphate or silver nitrate in injections for gonorrhœa, but administers a solution of the tri-bromide of gold and its combinations, in the treatment of syphilis, in place of the mercurials so generally and frequently so injuriously prescribed.

[Attention must be called to the necessity for keeping the electrode moving whenever the anode is applied to mucous cavities, otherwise it is apt to become imbedded in dried clot.]

Osteomalacia.—Dr. W. E. Fothergill (*Edinburgh Medical Journal*, April) in a paper on this subject says that the prognosis in osteomalacia is now much less gloomy than it was some few years ago, several lines of treatment having been rewarded with success. Bone marrow, cod-liver oil, and phosphorus, used with patience, are found to be the most useful drugs. Diet and hygiene are important factors in management, while salt water and other baths have proved very valuable in aiding metabolism.

The surgical treatment of osteomalacia has arisen naturally from the performance of the Cæsarean section as an emergency operation at full term. In most of the earlier cases Porro's operation was done, and as improvement or cure was frequently seen to follow, it was judged that the benefit derived from the operation was due to the removal of the ovaries. Accordingly, in 1887, Fehling began removing the ovaries with a view to curing osteomalacia, quite apart from pregnancy, and double oöphorectomy has become a recognized treatment for the disease even in women who have never been pregnant. Winckel mentions forty cases in which the ovaries were removed; of the sixteen which were observed for some time, twelve were cured and four improved, but he does not consider the results to be definite. Truzzi published in 1894 a table of ninety-eight operations, fifty-two of which were subsequently traced. There was complete cure in thirty-six; partial cure in four; cure after relapse in three; improvement in three; persistent relapse in five; and no change in one. Some authorities hold that the removal of the uterus, together with the ovaries, gives an additional chance of success, but this has also been followed by failure. It seems unlikely that the surgical treatment of osteomalacia, as apart from pregnancy, will become general; indeed, it has probably passed its perihelion, and will soon be less fashionable than it now is.

The consensus of present opinion as to the management of osteomalacia may be briefly indicated: 1. In men and in non-pregnant women, internal medication should always be patiently tried, together with hygienic and

dietetic precautions. In females, if the disease continues to progress, double oöphorectomy may be performed, and followed up by continued medication. 2. In early pregnancy, induce abortion and then treat as above. If a living child is specially desired, and the symptoms are slight, pregnancy may be allowed to continue, medical treatment being continued throughout. 3. In late pregnancy it is necessary to decide whether or not a living child can be born at term *per vias naturales*. If not, a choice must be made between the induction of premature labor and a pre-arranged Cæsarean section, as embryulcia should not be contemplated. 4. During labor, the child, if living, must be delivered alive by the method indicated by the circumstances of the case. If the abdomen is opened, the ovaries are removed, whether the uterus is also removed or not. Embryulcia is permissible only when the child is dead. Medical treatment must be continued after operation, as relapses frequently occur.

Hysterical Press Outcries against Hospitals and Ambulances.—An anonymous correspondent in the *New York Times* for May 2d, in a most forcible and dignified letter, protests against the charges made by the "yellow journals" against an ambulance surgeon of the New York Hospital. "Under such headlines," says the correspondent, "as 'She Dies, Ignored by an Ambulance Surgeon' and 'Wealthy Woman's Death is Laid to Ambulance Doctor,' several of the sensational journals of this city published a series of exaggerated and distorted charges calculated to do great injustice and harm to a man who fills this thankless position. Periodically such reports appear in their columns, and each time investigation shows that they have made a mountain of a mole-hill and only damaged the reputation of a New York physician. In the present instance . . . investigation shows that when first seen the woman refused to be taken to the hospital. When again called to her at the police precinct he [the surgeon] at once took her there. After calling an ambulance the police are obliged to secure some diagnosis to include in their report, and in this instance 'contusion of the arm and alcoholism' was given by the surgeon. It is useless for him to waste time in attempting to make an accurate diagnosis, as a public examination cannot be thorough, and the time lost would mean much to the patient in some cases. For this reason the most probable diagnosis is given and the patient is hurried to the hospital for examination by the house physician or surgeon and subsequently by the visiting physician or surgeon. When the offer of transportation to the hospital is declined the examination is naturally brief, and some diagnosis is given merely as a matter of form. The diagnosis of alcoholism as opposed to various injuries and affections of the head, some forms of poisoning, and certain diseases, is the most difficult which the ambulance surgeon is called upon to make almost instantaneously, and at times is impossible. This accounts for the frequency of confusion between alcoholism and apoplexy or fracture of the skull, conditions often found together. As the most common of these reasons for calling an ambulance is alcoholism, it was most natural that this diagnosis should have been given to satisfy the demand of the police.

"The ambulance surgeon of the 'yellow journals' is painted as young, incompetent, hasty, brutal, and conceited. . . . In reality those who fill this position in the best hospitals are picked men, who, though young, have won their positions by difficult competitive examinations open to all comers, and have served at least six

months in the hospital. Their lives are far from easy. They are on duty all day, assisting at operations and doing routine work, interrupted by hurried ambulance calls, which frequently deprive them of their meals and often arouse them from sleep four or five times during the night. The action of the 'yellow journals' in endeavoring to injure the reputation of such men in the city where they intend to practise is beneath contempt.

"Such reports are more commonly connected with the New York Hospital than any other for the following reason: It is considered a moral and legal obligation for a physician to maintain secrecy concerning the affairs of his patients, and the New York Hospital sets an admirable example to others less conservative in following this principle. The house staff are not allowed to make any statements for publication. All communications must proceed from the superintendent, and, as the hospital regards the affairs of patients as matters of professional confidence, 'yellow journalists' can obtain no assistance in creating sensational articles. For this reason they seize every opportunity to injure the hospital by exaggeration, insinuation, and fabrication. Will they give the acquittal of the ambulance surgeon by the Grand Jury the same prominence as their own damaging charges?"

Medical Society of the State of New York.—We are informed that at the ninety-fifth annual session of the Medical Society of the State of New York, held at Albany, N. Y., on January 29, 30, and 31, 1901, it was moved and unanimously adopted that, in order to increase the facilities for becoming permanent members of the society, each county society should be allowed to send five times the number of delegates it had formerly sent to the State society. These delegates are elected for a term of three years and are eligible for permanent membership if they register twice during that time. This will make the number of delegates from the county society to the State society 750 in all, or one delegate for every eight or nine members of county societies without increase of expense to the county societies.

It was further agreed, in response to a widely expressed desire, that the society hold a semi-annual meeting in the city of New York in the early autumn, to be devoted entirely to scientific work and social intercourse.

The officers of the society announce that they have engaged the New York Academy of Medicine for this purpose and that a meeting of two days' duration will be held there on October 15 and 16, 1901.

Members wishing to read papers are requested to communicate with Dr. Nathan Jacobson, 430 South Salina Street, Syracuse, N. Y. Information of any other nature can be obtained from Dr. Frederick C. Curtis, secretary, 17 Washington Avenue, Albany, N. Y., or from Dr. Frank Van Fleet, associate secretary, 63 East Seventy-ninth Street, New York.

It is further announced that the society will tender a reception to its members, delegates, and guests on the evening of October 15th at Delmonico's. Tickets of admission to this reception will be furnished without cost to all who register at the semi-annual meeting, as well as to the society's guests.

A Bengali Medical Journal.—We have received the March number of the *Chikitsaka-o-Samalochaka*, a monthly journal of medicine, surgery, hygiene, etc., published in Bengali, at Calcutta, and edited by Dr. Satykrishna Roy. As we have on our staff no parallel to the

gentleman who, according to Christian Science accounts, was recently able to think a correction into a carved granite block, for the purpose of thinking the Bengali into plain English, we regret that we are unable to give extracts. Seriously, though, it is gratifying to find such progress of Western medical science among Orientals, as must certainly be the case when a journal devoted thereto, and printed exclusively in an Oriental tongue, can obtain such support, necessarily almost entirely among native physicians, as to reach its seventh volume.

Newyorkitis is the title of a new work by Dr. John H. Girdner. Speculation is rife as to how this new disease differs from the old orchitis.

A Terrible Voyage.—The *Philadelphia Medical Journal* for April 20th relates the terrible voyage of the steamer *Chile*, which left Panama in July, 1900, bound south, and when two days out developed yellow fever. From this moment she was a doomed ship, an ocean outcast, a pariah of the deep. From port to port she sailed, begging in vain for succor and Christian charity, but was refused everything because she had a few cases of yellow fever on board. From port after port she was turned adrift; at one place she was even driven out of the harbor by a gunboat. This sort of thing went on until the west coast of South America had been pretty well skirted and the *Chile's* coal bunkers were exhausted. Then, of course, the helpless steamer could proceed by her own power no further. Gunboats could not drive her away, and it is a wonder that they did not stand off and sink her. The ports that had refused to give her medicines had also refused to give her coal, but the last port had to give her coal in order to get rid of her. So she was towed five miles out to sea, and coal sent to her in an old barge. The *Chile*, with her sick crew, had to unload the coal as best she could, and then sink the barge. No medicines, disinfectants, or supplies were granted at any port—only maledictions and orders to get out! There was no doctor on board; only an impostor, who claimed to be one. For six weeks yellow fever held high carnival; men were dying, and a lot of passengers were terrorized, and their lives put in peril, and all because there was no quarantine port on the west coast of South America, and because of the disgraceful panic that assails some communities at the mere mention of the name of yellow fever.

Yet the report on International Quarantine, adopted by the Pan-American Medical Congress, in the City of Mexico, 1896, provides, according to the *Public Health Reports*, that each government should maintain quarantine stations at its domestic ports.

The Respect Due to the Leaders of Medicine.—A native Indian physician, A. Mitra. Rai Bahadur, chief medical officer, Kashmir (*Indian Medical Record*, April 10th), in some excellent and dignified Words of Advice to Students and Young Practitioners in India, says:

"While attending an annual meeting of the British Medical Association, nothing impressed me more than to see the genuine respect which practitioners in England paid to their more well-known brethren in the profession. In the meeting hall, the entrance of a well-known physician and surgeon was hailed with an outburst of cheers and enthusiasm. No jealous eye, no whispered maligning. A nation in general, and a profession in particular, cannot rise until it learns to praise its great men."

Original Communications.

HYPERACIDITY
(SUPERACIDITY, HYPERCHLORHYDRIA,
SUPERACIDITAS CHLORHYDRICA);
A CLINICAL STUDY.

By H. ILLOWAY, M. D.,

NEW YORK,

FORMERLY PROFESSOR OF DISEASES OF CHILDREN, CINCINNATI
COLLEGE OF MEDICINE AND SURGERY; FORMERLY VISITING
PHYSICIAN TO THE JEWISH HOSPITAL, CINCINNATI;
FELLOW OF THE NEW YORK ACADEMY OF
MEDICINE, ETC.

As the last two titles indicate, *hyperacidity* refers to a condition of excessive secretion of hydrochloric acid by the gastric mucous membrane under the stimulus of food. It has no reference to any degree of acidity that may be due to extraneous acids, such as lactic, acetic, butyric, and other volatile acids developed from the various food matters taken into the stomach when that organ, for one reason or another, cannot secrete its normal acid or does so only in deficient quantity.

It had long been supposed, having reference now to the normal stomach only, that in the earliest period of the digestive process, preliminary to the secretion of hydrochloric acid, lactic acid was formed in the stomach and could be disclosed in the gastric contents. As late as 1891 this was still taught by Rosenheim in his work on the *Diseases of the Stomach*. The later and very exact investigations of Martius and Lüttke have disproved this and demonstrated that the acidity of the chyme is dependent in its totality (the acid phosphatic bases being in but minute quantity when they are present and, therefore, altogether unimportant factors) upon the hydrochloric acid secreted by the stomach.

The investigations of Bidder and Schmidt gave the proportion of hydrochloric acid in the gastric juice of the human being as about 0.22 per cent. Later investigators, basing themselves on a large number of observations, have given the normal proportion as ranging from 0.1 to 0.22 per cent. (or 1 to 2.2 per 1,000).

My own observations, made in over one hundred cases, seem to me to prove conclusively that for this country 1 per 1,000 cannot be considered normal. In all the cases in which the quantity was below 1.8 per mille, all the manifestations of an enfeebled digestion were present, and all of them were benefited by the administration of such acid. Neither can the figure 2.2 per mille be considered as the maximum normal limit, for some few of these persons had a considerably higher proportion (2.9 and 3.0 per mille) without any disturbance being caused thereby.

French writers place the maximum normal limit much higher than German authorities. Richet places it at 3.4 per 1,000, and Bouveret, while admitting that in general it does not go beyond 2.36, holds, nevertheless, that at times 4 per mille may be normal; for he says very

plainly, speaking of the various figures given by different authors, that he regards all degrees of acidity beyond 4.0 as pathological. I have not, so far, encountered any case that could be considered normal with a total acidity as high as that last referred to by Bouveret.

However this may be, this is very evident—a demonstrated fact which cannot be questioned—that there is a considerable range in the degree of acidity within what are considered normal limits. The reason therefor will be set forth elsewhere.

The *total acidity* of a given quantity of stomach contents removed from that organ at the height of the digestive process, usually calculated for 100 cubic centimetres, depends greatly upon the character of the test meal previously taken. It is higher for a test meal of Riegel and the test breakfast of Germain Sée, and lower for the test breakfast of Ewald and Boas, which, for good and sufficient reasons, is the one most commonly employed. Thus, as stated by Riegel, the total acidity after a meal made up partly of meat is about 75 (centimetres of a decinormal solution of potassium hydrate), while that after an Ewald and Boas test breakfast ranges from 40 to 60.

As to the latter figures, there is a decided difference among the various observers. According to Strauss, working in Riegel's clinic, the average total acidity in 170 cases (cancer excluded) examined by him was 62. This must necessarily mean that in quite a number of these cases the total acidity was much higher than 60. The tabulation of 92 cases from a Berlin clinic gives an average of only 47. Here the proportion of cases with a total acidity below 40 must have been quite large, and the number with total acidity at 60 or above it rather small.

My own experience, like that of Strauss, demonstrates that the normal total acidity after a test breakfast of Ewald and Boas has a higher range, at least here, than that given by Riegel. I tabulated 110 cases (cancer excluded) from my private case book, and then eliminated, as not belonging in the category of the normal, all the cases of *hyperacidity*; that is, the cases in which the manifestations of this morbid condition were clearly present, and all the cases of hypoacidity, *i. e.*, all the cases wherein the digestion appeared weakened, retarded, in consequence, as it were, of a deficiency in the hydrochloric-acid element of the gastric juice, and in which the administration of the acid appeared to remedy the trouble. Of the cases so eliminated, 23 were cases of hyperacidity and 20 were cases of hypoacidity, leaving 67 cases that could be considered normal.

The total acidities in those 67 cases were as follows: From 90 upward: One of 90; one of 92—2 cases. From 80 to 89: Two of 80; one of 83—3 cases. From 70 to 79: Five of 70; one of 71; one of 72; three of 73; two of 74; one of 75; two of 77; three of 79—18 cases. From 60 to 69: Five of 60; one of 61; one of 62; two of 64; one of 65; four of 66; one of 67; one of 68; one of 69—17 cases. From 50 to 59: One of 50; three of 51; four

of 53; one of 54; one of 55; three of 56; three of 57; four of 58; one of 59—21 cases. From 46 to 49: Four of 46; one of 48; one of 49—6 cases.*

This tabulation, even if we were to leave out of consideration the cases ranging from 90 upward as exceptional (though there would be really no good reason therefor), shows a much higher range for the normal total acidity after an Ewald and Boas test breakfast than has been set down, and certainly gives a much higher average than even that found by Strauss in the clinic at Giessen.

In *hyperacidity*, the morbid condition now under consideration, it is said—and it would naturally be supposed to be so—that the total acidities found are much higher than otherwise. Thus, we find it stated by Riegel that after a test meal (of which meat forms part) acidities of 100 are almost the rule, while even such as 150, 160, and over are not infrequent. After an Ewald and Boas test breakfast they range from 70 upward, and total acidities of 100 and even over are not rare.

In the 23 cases of hyperacidity coming under my observation, the total acidities after an Ewald and Boas test breakfast (at the height of digestion) were as follows: 52, 54, 56, 61, 69, 69, 69, 72, 74, 78, 79, 81, 82, 83, 87, 93, 93, 94, 94, 101, 104, 120.†

If, leaving out the last three, we compare these acidities with those of the 67 cases tabulated above and set down as normal, we are at once confronted by the facts that the total acidities in hyperacidity are not necessarily so much higher than the normal and that, furthermore, the same degree of total acidity may be normal in one case and abnormal in another.

Talma‡ explains it in this wise: The cases with the symptoms of hyperacidity and a total acidity within what are regarded as normal limits are not cases of hyperacidity at all. There is no undue quantity of hydrochloric acid secreted by the stomach here; what we do have is an abnormal sensitiveness, a hyperæsthesia, of the gastric mucous membrane to hydrochloric acid, and to this the morbid phenomena are due. Now, this explanation does not explain at all; for in fact, so far as lies within our knowledge to-day, that is all there is to hyperacidity. The hyperæsthesia constitutes, if we may so say, the hyperacidity, and it is only in this morbid condition and not otherwise that we find a hyperæsthesia to hydrochloric acid *alone*.

The true explanation that solves all difficulties, that is founded upon well-known physiological laws, is this, and very simple it is indeed: Every stomach has in this

*In the cases eliminated as belonging to the category of hypoacidity the range was as follows: From 40 to 45: One of 40; four of 42; three of 44—8 cases. From 30 to 39: Two of 31; two of 32; one of 33; two of 34; one of 35; one of 37; one of 38; one of 39—11 cases. From 20 to 29: One of 27—1 case.

†In one of the cases a sufficient quantity to measure the total acidity, according to the method employed in the other cases, could not be obtained by reason of an insufficiency of the pylorus, which caused a very early and a very rapid discharge of the ingested material from the stomach.

‡*Zeitschrift für klinische Medicin*, Bd. viii, 1884.

regard a physiological individuality of its own, and thus the one organ may perform its function—digestion—perfectly with a degree of acidity that might be insufficient or more than sufficient for another. Any further addition to this normal proportion of hydrochloric acid must render that particular gastric juice hyperacid and provoke the manifestations dependent upon such a condition.

From the foregoing it is very evident that in the great majority of cases we cannot, upon the total acidity alone, predicate a condition of hyperacidity, and that it is only when other symptoms, such as are usually attendant upon this condition, are present, that we are justified in classifying a given case as belonging to this category.

However, as has already been indicated at the outset, it is not a question of total acidity merely. In fact, so long as the great bulk of the hydrochloric acid secreted is taken up by the albuminous food matters introduced into the stomach, there is no hyperacidity. It is only when much more is formed than can be taken up that a hyperacidity may be said to be present. It is a fact well known to all that in the stomach contents extracted at the height of digestion from a fairly normal stomach, a certain amount of free hydrochloric acid, *i. e.*, that has not been taken up by the nitrogenous matters ingested, but has remained in its free state, just as it had been secreted, is found and is recognizable by certain tests which respond to free acid alone. If there is an excessive secretion of hydrochloric acid much more than is required for digestive purposes, the surplus remaining free must naturally be large, and, as Riegel has well said, it is this large amount of free acid that sets up irritation of the gastric mucous membrane and thus provokes the manifestations of hyperacidity.

The important point, therefore, especially important for diagnosis, is to determine the amount of free hydrochloric acid present in a given example of stomach contents. To do this, we need but avail ourselves of the simple method of Mintz—a method upon which all authors are agreed that it gives exact and reliable results. This method has also this advantage, that we can at once learn the proportion of the combined hydrochloric acid present by simply subtracting the proportion of free acid found from the total acidity. The result will represent the proportion of the combined hydrochloric acid.

But there is still another difficulty, namely, this: Having ascertained the amount of free acid in a given specimen of stomach contents, we have no standard of comparison wherewith to gauge whether it is of normal proportion, below normal, or excessive. Some authors, it is true, give certain figures as to what they consider an excess of free hydrochloric acid, but that is not a sufficient guide. We have seen, in the consideration of total acidity, that there is considerable individual* variance in this, and that there appears to be considerable variance

*As regards the different individuals.

in the different countries; it is, therefore, but very reasonable to presume that there should be a similar variance in the proportion of free acid present. Exact and detailed studies on this point, which, so far as my knowledge goes, have not as yet been made, are absolutely necessary if we are to be enabled to draw the correct conclusions from the results of our examinations.

My own investigations in 27 of the 67 cases tabulated above, as having a normal gastric juice, gave the following results:

TABLE A.

Cases.	Total Acidity. <i>Measured by a properly standardized decinormal solution of potassium hydrate.</i>	Free Acid <i>(after Mints).</i>
1.....	46	16.
2.....	46	10.
3.....	46	04.
4.....	48	13.
5.....	49	05.
6.....	51	21.
7.....	51	22.
8.....	53	12.
9.....	55	27.
10.....	56	10.
11.....	57	33.
12.....	57	26.
13.....	58	32.
14.....	58	11.
15.....	58	26.
16.....	58	12.
17.....	60	18.
18.....	60	46.
19.....	60	11.
20.....	62	26.
21.....	64	21.
22.....	64	17.
23.....	65	05.
24.....	69	43.
25.....	72	30.
26.....	73	51.
27.....	74	39.

In all these cases the same test breakfast—that of Ewald and Boas, was given, and the same time as to extraction, an hour after ingestion, was observed.

The foregoing table would give us the range of normal limits for free hydrochloric acid from 4 to 51, a range as great as that for total acidity. Whether below 5, the point where resorcin ceases to show any reaction, but where the Günzberg test still gives it decidedly, should be considered as indicating a deficiency, I have not, with the material at my disposal, been able to determine and have, therefore, counted in here, in the tabulation of normal cases, the case with free acid of only 4.

The table also shows another and very important point, viz., that we may have a high degree of total acidity and a small amount of free acid, and *vice versa*. Thus, in case 23, with a total acidity of 65, there was but 5 of free acid, while in case 1, with a total acidity of 46, the proportion of free acid was 16. Again, in case 26, with a total acidity of 73, we have free acid 51, while

in case 27, with a total acidity of 74, the free acid proportion is but 39.

This but serves as an additional demonstration of the truth of the proposition set forth above as to the physiological individuality of every stomach.

As to the proportion of free acid found in cases of hyperacidity, Riegel says that after a test meal figures of 60, 70 and even 80 (= 2.1, 2.5, 2.9 per mille), are not infrequent, and after a test breakfast of Ewald and Boas, proportions of 50, 60 (= 1.8, 2.1 per mille) are more commonly met with.

Bouveret makes the general statement that he has occasionally found the proportion of free hydrochloric acid to reach 2 and even 3 per mille—a proportion, he adds, much higher than normal.

The results obtained by me in 12 of the 23 cases of hyperacidity already referred to, after an Ewald and Boas test breakfast, were as follows:

TABLE B.

Cases.	Total Acid.	Free Acid.	Per Mille.
12.....	81	33	1.2
13.....	69	44	1.6
14.....	90	40	1.4
15.....	98	53	1.9
16.....	120	64	2.3
17.....	94	53	1.9
18.....	74	40	1.4
19.....	54	18	0.6
20.....	56	33	1.2
21.....	52	13	0.4
22.....	61	35	1.2
23.....	69	35	1.2

The results of this tabulation fully confirm the statements of the authors above referred to. The table demonstrates, furthermore, that after an Ewald and Boas test breakfast the lower proportions of free acid are the rule, while the higher figures (2 per mille and upwards) are only rarely met with.

One point therein deserves particular notice, and that is this: Two of the cases had, as seen, proportions of free acid of only 0.6 and 0.4 (per mille), respectively, and, still, in both the phenomena of hyperacidity were more acutely defined and they responded to the other tests (as to effects of albuminous food, digestion, etc.) more sharply than any of the others of this series of 23 cases.

Comparing the figures of this table with those of Table A, we find that, as a rule, they are higher here than there; still, even there, in the normal cases, we occasionally find proportions of free acid as great as any noted here; therefore this feature also cannot be said to be sufficiently characteristic, pathognomonic, as to justify, upon it alone, a diagnosis of hyperacidity.

The conclusion arrived at and noted above is again confirmed. We cannot upon the *total acidity* alone, upon the proportions of *free* hydrochloric acid alone, or even on both combined, classify a case as one of hyperacidity; for that, the presence of the other symptoms in combination with these is absolutely necessary.

This morbid condition may present itself to us under two forms—the *acute* and the *chronic*.

I. Acute refers here more particularly to time, sudden onset, and rapid transition, but sharpness of suffering is not necessarily excluded. This form, as indicated, is of very transitory character, coming on suddenly and lasting not more than a few hours, when it is relieved either by extraneous measures or by Nature.

II. The chronic form may be of any duration, from one month to ten years.

Hayem* and Mathieu† have described another—a third—form, which they designate *latent hyperacidity*. By this they mean to say that a given person, though he eats well, enjoys his food, has *no manner* of gastric distress at *any time*, looks well, and feels well, must, nevertheless, because his total acidity happens to be somewhat high, be latently sick, have a latent hyperacidity. It has already been shown how deceptive the matter of the total acidity is, and for the further reasons there set forth I should certainly reject any such form.

SYMPTOMATOLOGY.—The symptoms of this morbid condition, and there are morbid manifestations in all cases, are varied both in character and in intensity. Though none of them is pathognomonic, they are, nevertheless, sufficiently characteristic, and in conjunction with the results of the examination of the gastric chemismus, enable us to arrive at a correct conclusion.

Objective Symptoms.—I. The general appearance of the patient is most commonly good, *i. e.*, he is in fair flesh. Though he may give a history of long ailment, though he may have dieted to an extent, even though there be a line of suffering in his face attesting the severity of the pain endured, nevertheless his body does not show any marked loss of flesh; on the contrary, the fullness of his body is in striking contrast to his history of long suffering. In only one case have I noted any considerable reduction in flesh—a veritable leanness—and this was in a boy of twelve, who had, for over six months, reduced himself to a minimum of food (mainly coffee and a roll or cake), and at the conclusion of each meal vomited, or, as he maintained, expressed voluntarily a considerable part of even that, on account of the pain caused thereby and the relief obtained by the discharge thereof. He had refused absolutely to take more food, as entailing even still greater suffering.

The patients are not usually fleshy, but even in this respect there are exceptions, as already noted by Riegel. One of my own patients—a woman with a history of long-standing gastric trouble and decided dieting—showed, nevertheless, a marked adiposity, maintaining a weight ranging from 186 to 192 pounds (according to the season, the greater weight in autumn and winter, the lesser in summer).

II. The appetite is, as a rule, fair. In many cases it is very good. The patients can eat and do eat fairly

well, and many eat often, some because they feel empty and hungry, others because they find that when they put something into their stomachs they relieve themselves of the uneasy sensations therein, even of pain. It is only in cases in which the patients have reduced themselves to a very abstemious diet and kept to the same for a long time that I have found the desire for food wanting. It may be that the impression made upon their cerebral centres that more food would be hurtful is responsible for the lack of desire for food, for I have noted that as soon as these patients were ordered to eat well and assured that it would do them no harm, but, on the contrary, would do them good, the appetite returned with the first good meal taken and the experience that no evil had resulted therefrom.

III. Vomiting is of rare occurrence; that is generally admitted. It occurred in but one of my 23 cases—the boy of twelve already referred to—and he maintained, as already stated, that he expressed the surplus, as it were, taken in, voluntarily, because it caused him pain and its discharge relieved him; but he could keep it down if he wished to, only he would have to stand the pain. Later on, after coming under treatment with me and after I had compelled a marked increase in his food, he did occasionally vomit some, more particularly after his noon-day meal, and he noticed that the tendency thereto was increased by drinking sweetened tea after the meal.

It is said to follow generally in the wake of a gastralgic attack when the paroxysm is at its height. The vomited matters are very acrid, usually cause a sensation of burning or scalding in the oesophagus, and numb the teeth as they pass over them. This latter effect is a certain indication that free hydrochloric acid is largely present, for it does not occur when this is wanting, even though other acids are present in abundance. Otherwise there is nothing peculiar about the ejecta except that they show a very early and very rapid digestive action.

IV. *Examination of the Stomach, External.*—There is nothing abnormal apparent on inspection, no distention or fulness of the epigastrium. As to pain or tenderness, there is some difference of opinion among authorities. Bouveret says that the stomach is painful to marked pressure, while during a gastralgic seizure even the light pressure of a finger causes pain. Riegel maintains that in the intervals there is neither pain nor tenderness to pressure.

Of the 23 cases forming the basis of this paper, in 15 the patients had no particular or unusual sensitiveness of the gastric region to percussion with either finger or hammer. Eight had more or less tenderness in the epigastrium. In six of these latter, the situation of the greatest sensitiveness was in the median line, beginning at about 1 to 1½ centimetres below the point of the xiphoid cartilage and running down a variable distance, from 4 to 7 centimetres. In one case it was most marked in the left half of the epigastrium, and particularly near

*Société médicale des hôpitaux, May, 1895.

†*Traité de médecine*, Charcot, Bouchard et Brissaud, Vol. iii.

to the border of the costal arch. In the eighth case, in a male, there was, besides the central tenderness in the epigastrium, some sensitiveness in the right and left iliac regions (about 7 centimetres below the umbilicus and 1½ and 2 centimetres respectively to the right and left of the median line).

Of the 15 patients, two had gastralgic seizures, which on the whole were not of very severe character. As in the other cases thus affected, so in these there was more or less tenderness or soreness of the epigastric region, particularly the left half thereof, during the paroxysm and for a short while thereafter.

V. *Examination of the Stomach, Internal.*—The results of the examinations of the stomach contents in cases of hyperacidity, in so far as the hydrochloric-acid element is concerned, separately and together, have been already fully set forth. As to the *peptic* constituent of the gastric juice and the *rennet*, it has been assumed that they also are secreted in increased proportions. Some investigations, however, latterly made, seem to indicate that this is not necessarily so, but that there may be increase of hydrochloric acid without corresponding increase of pepsin or of rennet. Be this as it may, of this much we are certain, that, even if there is no increase, the full normal quantity, *i. e.*, the quantity normal to that stomach, is formed.

In consonance with the increase in secretion of the gastric juice, or at least of one of the most important elements thereof, there is greater rapidity in the digestive process. I have found the Leube test meal (with the addition of stewed fruit or, preferably, stewed tomatoes with a little of the peel retained for purpose of ready recognition) fully digested at the end of five hours and the stomach then either empty or containing but a little scum consisting of fat globules, a very few starch cells, and some vegetable detritus. Riegel has occasionally found digestion completed and the stomach emptied at the end of four hours. There is, however, nothing characteristic in this, and I have obtained similar results in persons with a gastric juice rich in hydrochloric acid, but with none of the other stigmata of hyperacidity.

As a result of investigations made by himself and by others working under his supervision, Strauss* professed to have found that in stomachs affected with hyperacidity the contents, after an Ewald and Boas test breakfast, presented certain peculiarities which were not found with other morbid states of that organ. In an article published more recently, Schuler† has again set forth these peculiarities, affirming that they are pathognomonic and that upon them alone a diagnosis can be correctly based. They are as follows:

1. The stomach contents are unduly large in quantity, even the minimum found exceeding by a considerable

number of cubic centimetres the quantity ordinarily met with.

2. The contents are mainly, almost entirely, fluid, but very little solid matter being found therein. To this is added the further qualification, that the stomach is sufficient as to its motor function, *i. e.*, the gastric muscles are of normal force and competent to accomplish their work in a normal manner. In view of the last qualification, the presence at the height of the digestive process of so large an amount of fluid is accounted for by an exaggerated secretion on the part of the stomach of the diluting fluid,* a pouring out so extensive that the authors above referred to speak of a hydrorrhœa gastrica in this connection.

3. The specific gravity of the filtered stomach contents is much lower than that of filtered stomach contents from organs not so affected.

4. Amydulin is present in abnormally large quantities.

(To be continued.)

NASAL CONDITION OBSERVED IN THE AGED.†

By BEAMAN DOUGLASS, M. D.,

NEW YORK,

PROFESSOR OF DISEASES OF THE NOSE AND THROAT, POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

LAST year, in studying nasal lesions in people who were over forty-five years of age, I made it a particular point to examine carefully all cases which came under my observation in both private and hospital practice. When I began to look for these cases of nasal lesion in old people I was very much impressed with the fact that people more than fifty years of age either did not suffer from nasal lesions or else did not complain of them. I also remarked, in the course of my search, how few elderly people were seen in our clinic at the Post-graduate and in the Manhattan Eye and Ear Hospital, and I was forced to ask my friends and acquaintances to submit themselves for examination that I might determine, if possible, the presence or absence of nasal lesions in the aged.

In this series of cases the age of forty-five years was determined upon as the proper time of beginning old age, principally because the oculists tell us that at the age of forty-five the first appearance of senile degeneration begins in the cornea, and from this time, judging from the eye, we begin to consider men and women old. The few cases which have come under my observation will not permit the drawing of any very full conclusions, but

*Strauss and Roth, *Zeitschrift für klinische Medicin*, Bd. xxxvii. As a result of their investigations, they maintain that the stomach secretes two fluids, one the gastric juice proper, and the other a neutral fluid which is supposed to have the function of diluting the acid secretion.

†Read before the Section of Laryngology, New York Academy of Medicine, April 24, 1901.

some of the cases are so interesting that, although the number is not large, some deductions can be drawn from them, even if not enough for statistical purposes.

The majority of the patients examined were from the middle walks of life, but a few were dispensary cases. All cases in which the intelligence of the patient was insufficient to obtain a complete and satisfactory history, and all cases where there was any doubt in the mind of the patient as to the accuracy of his statement, were rejected, so that the number of cases accepted and presented represents a carefully obtained history of the points studied. I do not know that this class of cases is at all important as a contribution to rhinological literature, or that the deductions which I can draw from so few cases can be considered of much value, nor am I sure but that the experience of other men may completely contradict the conclusions which I have drawn from these cases. At any rate, it is interesting to note that, at least in my experience, very few people over fifty years of age seek advice for the relief of nasal troubles, while the majority of patients who seek advice, either at the hospital or in private practice, are between the ages of sixteen and forty years. Middle age, then, would seem to be the time when nasal affections, particularly of a catarrhal or inflammatory variety, are most rife, when they cause the most symptoms, and when the symptoms are severe enough to cause the patients to seek medical advice. We also remember that it is not uncommon in early childhood to have catarrhal affections of the nose and pharynx so developed that patients and parents seek the necessary advice for the relief of these conditions. It is, indeed, a striking fact that so few people in the declining years of life seek advice for nasal and pharyngeal affections. For in this period of life, with its decreasing vitality, the greater liability to disease is not diminished and we should expect the aged to complain of the effects and symptoms of nasal and pharyngeal inflammation. If then, in the aged, we find so few seeking advice for the relief of these conditions, it must be because in some way, although the lesions are present, they do not then cause the symptoms that they give rise to in earlier life. It is difficult to explain why, if nasal lesions are present, they should not cause as many symptoms in the aged as they do in early life. Perhaps it is because there is a lessened demand for nasal functional activity as age advances, or it may be possible that the system demands that less moisture and less heat should be given to the inspired air. If this is true, although I am not prepared to state that it is so, we could readily understand the fact that few old people apply for relief from nasal affections. If this is not the case, I cannot see any reason why there should be a cessation of catarrhal conditions in the aged. So far as I have been able to observe, there is no diminution of the sense of smell. I have found, by superficial tests, that the sense of smell is very well preserved, even after the senses of sight and hearing have begun to be impaired.

All of the cases observed did not present conditions which could be used in the construction of this paper, for a few of them complained of the ordinary symptoms of catarrhal lesions, and a few suffered from minor conditions, such as papillomata or eczema naris, which did not in any way influence the nasal condition. Many were eminently interesting and illustrated certain points which I wished to develop. Probably, then, the consideration of a few of these cases will be excuse enough for writing one or two rather dull histories.

CASE I.—T. V., a man, aged sixty-three years, had injured the nose, producing obstruction forty years ago. Previous history is otherwise without interest. He does not complain of headaches, but has some pharyngitis. The nasal obstruction is unilateral and has been treated by medical means. Since the accident there has been complete and permanent obstruction of the right naris; the sense of smell is unimpaired. Deafness began twenty-five years ago, with a dry catarrh of the left ear.

The following nasal condition is noted on examination: The left inferior turbinated body is markedly hyperplastic; it is fitted completely into the concavity of the nasal septum, the septum being deflected to the right side. In the right naris there is marked deflection of the cartilaginous septum and of the part of the bony septum in the region of the inferior meatus, so that there is absolute obstruction of the right side of the nose, and respiration through this nostril is an impossibility. This obstruction lies firmly against the inferior turbinate body on the right side. In this case, although there has been permanent obstruction for forty years, it is not accompanied by hypertrophy of the middle or inferior turbinate bodies of that side. On the opposite side to the one obstructed, there is marked hypertrophy of the inferior turbinate body, which fills in a concavity produced by the deflection, but not so entirely as to prevent nasal respiration.

This case is interesting, for it shows the possibility of a long-continued nasal obstruction without either hypertrophic or atrophic changes occurring in the obstructed side, while there is a marked inflammation on the free side; viz., marked hypertrophy of the inferior turbinate bones, and the middle turbinate bone of the same side is still normal.

CASE II.—H. R., a woman, aged seventy-five years. This patient has been a trained hospital nurse for more than thirty years. She is, therefore, qualified to speak of her present and previous history, since her whole education would tend to make her observant. Her previous history is absolutely correct. She denies headache, nasal obstruction, digestive disorders, and all other conditions which may have influenced her nasal lesions. She also states that she never has had catarrh and has been subject only to colds which affect the chest, never involving the nose. She has never had laryngitis or pharyngitis, and has had cough only when she has had a cold on the chest. At the present time she denies headache, discharge, obstruction, deafness, cough, and hoarseness, and states that her sense of smell at the age of seventy-five is not at all diminished; if changed at all, it is a little too keen. In view of the absolute absence of any history of coryza or any nasal trouble, the examination of this patient is very interesting.

In the left naris the mucous membrane is of good color and there are two thickened localities on the nasal septum, one opposite the inferior, and another opposite the middle, turbinate bone. The left middle turbinate bone is very much enlarged, filling up the whole middle meatus, and its surface is fairly flat, not rounded or bulbous as in hypertrophic conditions. The inferior turbinate also presents a plane surface and is without contact with the septum. Its tissues are non-contractile under cocaine. This middle turbinate body is much enlarged and probably contains an accessory bony cell.

In the left naris the mucous membrane is pale, and the middle turbinate body almost entirely hidden by an exostosis of the nasal septum which is in front of this middle turbinate, running slightly from below upward. Between this and the middle turbinate contact with the septum in its lower part is a concavity which further down shows the presence of an echondrosis of the septum, which is developed well in front of the inferior turbinate body, and which lies in contact with the inferior turbinate body. Under cocaine these tissues are absolutely non-contractile. The pharynx is normal, the mucous membrane is soft and moist, and the other parts of the respiratory tract are normal.

At the end of the examination the patient repeated her statements that she had never had a cold in the head and the nose had never been affected in any way. She further stated that she had never had to use a handkerchief for nasal discharge.

This case is in some ways remarkable, for it shows that, while this patient has never had acute rhinitis, there are in the nose conditions on the right side which are evidently pathological. If we acknowledge that the cystic turbinate in the left side might be the result of abnormal anatomical development, and even if we do not consider the thickening of the nasal septum as pathological, there still remain on the right side three pathological hypertrophic conditions which cannot be accounted for from the history of the case: The echondrosis low down in front, its contact with the inferior turbinate, which is certainly not normal, neither is the exostosis, further back in the middle meatus, nor is the firm contact of this exostosis normal.

CASE III.—The next case is one of considerable interest, since it occurs in the person of a man, sixty-one years old. This man has been a specialist in rhinology for several decades and can speak authoritatively upon matters regarding the nose and its conditions. The history runs as follows:

Previous history and family history good. He is, with the exception of digestive disorders, in perfect health; has never had catarrh or anything requiring surgical treatment of the nose. At the present time, has no headache, the sense of smell is good and undiminished; has no cough or hoarseness. He says that there is occasionally some cold in the head, a form of acute coryza which readily subsides, and he has never noticed between times any catarrhal condition. There are no ear symptoms.

The nasal condition on examination is as follows: The left middle turbinate tissue is paler than the other part; there is some difficulty in seeing a considerable part of this turbinate, since it is hidden by the hypertrophic condition of the nasal septum. This hyperplastic condition of the nasal septum is in the region of the

middle meatus, lying in front of the turbinate body, and extending far enough backward to meet it and cause a firm contact of this turbinate with the hyperplastic tissue of the septum.

The left inferior turbinate is normal. On the right side the middle turbinate also lies in contact with the septum, the hyperplastic tissue of the septum on this side extending further back than on the left. The septal condition on each side is much the same and consists of two pathological conditions. Above, in the region of the middle meatus on each side, it is considerably thickened; the rest of the septum is normal until near the floor of the nose, only the anterior part of the septum is considerably thickened near the floor. The whole of the septum is deflected toward the right side in such a way that the deflection extends from below in front, upward and behind. The condition of the septal mucous membrane varies so far as swelling is concerned. Sometimes it is swollen so that the right middle turbinate is entirely hidden from view.

Posteriorly on each side of the nasal septum there is a condition known as thickening of the posterior end of the septum. Although no symptoms arise from this condition, we find on the left pharyngeal wall a considerable patch of inflammation behind the posterior pillar. The posterior pharynx contains varicose veins, and the entire posterior pharyngeal wall is in that condition known clinically as granular. The lingual tonsil presents aneurysmal dilatations of the veins, and the veins across the back of the tongue are varicose.

The right vocal cord presents a nodule, but is otherwise normal.

If any one is capable of speaking authoritatively of his history certainly this patient is, and he distinctly states that, with the exception of occasional attacks of acute coryza which have rapidly subsided, he has never had any symptoms of nasal catarrh. Examination of the nose, however, reveals pathological conditions which, if found in patients complaining of persistent nasal obstruction and hay fever, inaptitude for work, and chronic headache, would be considered causative factors in these conditions. In this case the interesting question arises as to why, if pathological lesions are present, the symptoms which so often arise from them are absent: and another query as to why these lesions are present at all without the presence of a chronic catarrh is equally puzzling. These points will be dwelt upon later.

CASE IV.—A woman, fifty-five years old, family history good; has suffered only from fresh colds, which have lasted two or three weeks, and the nose has never been involved. In this patient there is some headache; she has complained of a full feeling in the head and headache at the time of taking cold. At the present time the functions of the nose are performed perfectly and there is no sensible nasal obstruction and no ear symptoms. Examination of the nose, however, reveals the fact that this patient has undoubtedly the symptoms of obstruction. On the right side the mucous membrane is hyperæmic, and there is also swelling of the erectile tissue. The inferior turbinate is somewhat shrunken. The right side of the nose is better than the left, the relation of the parts being normal. On the left side the middle turbinate lies in contact with the septum, which is decidedly projecting. The septum is thickened and the mucous

membrane is hyperæmie. In the pharynx there is a condition of granular pharyngitis and the tissue behind the posterior pillar of the fauces is thickened and markedly infiltrated.

It would seem as if this patient complained more of her attacks of rhinitis than the preceding patient, although the lesions are somewhat similar. In this case it is worth mentioning that, between the attacks of cold, which generally occur two or three times a year, there is absolute cessation of all nasal symptoms, this patient being certain that there is no nasal flow.

CASE V.—The next patient, a man, fifty-eight years of age, gives an absolutely negative history, stating that he never has had a cold and never has had to use a handkerchief on account of moisture or discharge from the nose or post-pharynx. The functional activity of the nose is perfect. There is a mucous or watery secretion when the nose is irritated with mechanical means, dust, etc. He states most positively that he has never in his life had any form of disease of the nose, throat, or pharynx; never was sick a day in his life; never had indigestion; and only once had a little rheumatism of the leg which did not prevent his attending to business.

This is a very instructive case because in the nasal examination, in spite of the absolutely negative history, we find a well-marked *ecchondrosis* on each side of the *sæptum* which, on the right side, impinges upon the inferior turbinate bone. All of the organs of this patient are absolutely normal, as well as the urine.

The right middle turbinate lies against the *sæptum* and also impinges upon the outer wall of the nose. The right side of the *sæptum* is deflected through the development of an *ecchondrosis*, which is large enough to impinge upon the inferior turbinate bone on the same side. It shrinks under cocaine *anæsthesia*. The left middle turbinate is swollen about its anterior end, is glossy, and gives one the impression that its mucous membrane is *oedematous*. Another *ecchondrosis* is developed against the left side of the *sæptum*, but it does not impinge upon the inferior turbinate bone. The pharynx, larynx, and post-pharynx are normal.

These five cases illustrate the point of view from which this paper has been written. Many of the remaining cases do not illustrate the particular points which I desire to bring out, and need not be considered here. In one of the cases the patient denied all history of having *catarrh* until after she was sixty years old, and asserted that the form of *chronic eoryza* from which she suffered was developed after that period. Other patients presented varying lesions, such as *papilloma*, *polypoid growths*, *ethmoiditis*, etc.

While there is no denying the fact that aged people may suffer from all the lesions and from the symptoms of which younger people always complain, yet it is rare to find them complaining. In two or three of these patients bits of the hypertrophic tissue were taken for microscopic examination, but no change could be found in the nasal tissue of elderly people that differed in any way from the pathological conditions in the younger cases, except that it seemed to me that the adenoid layer of the mucous membrane just beneath the epithelium

seemed, in the few cases examined, to consist of fewer cells than is usually considered normal.

The first point of importance in this class of cases is the occurrence of marked pathological nasal conditions without the production of any symptoms. This is particularly marked in one of the histories where the quality of the testimony places the history beyond doubt; namely, in the case occurring in the person of an eminent rhinologist. You will remember that this person presented marked hypertrophic changes of the nasal *sæptum* with contacts of the middle turbinate with the *sæptum*, and yet the patient was quite positive in the statement that this was not the result of previous inflammatory conditions, nor had the condition presented produced any nasal symptoms. The query then arises as to why, if definite pathological conditions are present, they do not always produce symptoms in one case, while in another patient these same lesions would produce profuse *catarrhal discharge*, constant *headache*, and a sense of nasal obstruction.

There seems to be, in most cases, a direct relation between the production of a lesion and the symptoms which arise from its presence, and it has not been observed by me, except in aged people, that patients present marked pathological conditions of the nose without symptoms. This is true more particularly regarding discharge than regarding symptoms of pain, for in most patients having hypertrophic, obstructive lesions, it is a fact that, so soon as the lesions are sufficiently developed, discharge is one of the symptoms. Pain may or may not be present.

Now, in these elderly people, hypertrophic lesions have developed without the symptoms of *catarrh*, such as are usually found in such conditions. What can be the cause?

At once the inflammatory theory, that is, exposure to cold, irritation from dust and fumes, changes of atmospheric condition, must fall to the ground as the causative agent in these cases which have been cited; for, when these act as active producers of lesions, it is safe to assert that they are invariably accompanied by a certain amount of *catarrhal discharge*, enough, at least, for the patient to notice and complain of; while in the case cited discharge has been denied. It is also certain that these lesions are not present without some cause, and we search for external conditions and find them absent, we must look for the production of these hypertrophies without ordinary symptoms from some cause which may lie within the body itself; namely, either a blood condition or some agent which acts while the nose is secreting water or radiating heat. If such an irritation could be produced from a blood condition which would act gently and so constantly that it might not produce symptoms, and would yet be sufficient to produce an irritation which would increase the quantity of connective tissue of the mucous membrane, we could have, at least theoretically, a hypertrophic lesion beginning without any inflammatory condition. If the blood or the lymphatic

fluids in the nose contained any substance which would act as an irritant, such as a foreign salt, uric acid, some animal toxine, or some chemical of which we know nothing, a constant and slow irritation might produce the increase in connective tissue which we find in these lesions. Such a condition is not unknown in other parts of the body; for instance, in the liver a cirrhotic condition may be developed through the constant irritation of alcohol or partly digested food products, and the whole liver may be changed microscopically into partial masses of connective tissue without the production of any symptoms. The same is found in the brain, where sclerosis may be established so gradually that the lesion is well advanced before symptoms appear. The same is true in chronic nephritis, where interstitial changes take place in the connective tissue of the kidney without the least production of any condition in the urine which would indicate the presence of such a change. Is it not therefore possible to explain these cases on the same grounds—that these changes may occur so gradually and yet so constantly that the lesions in the nose may be present from internal blood or lymphatic irritation, while active inflammatory symptoms, such as obstruction from paralysis of blood vessels, discharge, and pain, may be entirely absent?

We have already remarked that fewer old people complain of nasal catarrh than do younger or middle-aged people. This series of cases, however, shows that the fact of elderly people having nasal lesions is not uncommon. Why, then, are symptoms of these lesions not presented by elderly people, while the same amount of lesion in younger persons is active in the production of symptoms of which the patient complains enough to seek medical advice?

We know that younger people show an increased tendency to catarrhal symptoms; we know that temperament plays an important part in the production and quantity of symptoms. It is also a fact that, at times, younger people have even developed nasal lesions which have periods of inactivity. This is particularly marked in atrophic lesions. The reason for this is not altogether clear to my mind. It may be explained on two hypotheses: That the physiological activity of the nose has been increased so as to overcome the damage from the lesions, or that the lesion, with its resulting discharge and reflex pain, is, in some way, less active, and allows the nose to resume its physiological functions.

It is possible that as the system grows older elimination is decreased, and there is a lesser demand on the part of the inspired air for heat and moisture to satisfy the physiological function of the respiratory tract. So far as I know, this point is not susceptible of proof; yet the total absence of symptoms in these cases which presented lesions can only be explained in some such way. It would seem as if the theory of increased physiological capacity is better than that of lessened capacity on account of age. For, so far as superficial tests in regard to

the sense of smell are concerned, I have not found in elderly people a diminution of this sense. It is impossible to estimate the functional capacity for exudation of water or radiation of heat.

Why symptoms do not develop in these cases where pathological lesions are present is not easy of explanation. In other than aged people we find that nasal symptoms are naturally largely dependent upon active inflammatory conditions. It seems also true regarding the symptoms of secretion and obstruction that they are most apt to be developed in proportion to the degree of irritation from the inflammation present in any given case. If these lesions have been produced without any inflammatory disturbance as we understand it, disturbance of circulation, innervation, and exudation—that is, if the irritation has been so slow and so prolonged as to produce hyperplasia without functional disturbance—we should have these lesions fully developed without their having presented any symptoms sufficient to attract the attention of the patient. It is difficult to recognize such slow, gradual irritation, and we assume the process to be hastened from time to time by slight acute inflammatory disturbances. Probably, in these patients, such conditions have arisen, but have been so slight as to have been quickly forgotten. Symptoms of secretion, that is, alterations in quality and quantity of nasal secretion, seem in some way to be associated with conditions of circulation, loss of blood-vessel tone, chronic congestion of the nasal tissue, with exudation of leucocytes, oedema or serous infiltration of the interstitial connective tissue spaces in the nasal mucous membrane—conditions which give rise to discharge. If the blood circulation is fairly active in the nose and yet is pathological in regard to the solids which it holds in solution (uric acid, unknown salts, organic poisons), it is possible that these dissolved materials may invade the mucous tissue of the nostril, and that exudation from the capillaries or some obstruction in lymphatic circulation may leave them in the tissue. This would produce a very slow mechanical interference with the cell activity, and might account for the increase of connective tissue cells without the production of discharge or symptoms.

The symptom of pain, together with those of reflex phenomena, seems to depend, not so much on the quantity of inflammation or upon the degree of circulatory disturbance and lymphatic obstruction, as upon a certain condition of the nervous structures that are distributed through the nares. Headache, hay fever, reflex cough, asthma, tracheal irritation, throat cramp, and certain functional brain disturbances, such as inability to concentrate the mind, aphasia, and sometimes vertigo, are symptoms which in many cases seem to depend directly upon irritation of nasal nerves. In some patients who have marked lesions without neurotic tendencies these reflex symptoms are entirely absent; while other patients, having marked neurotic tendencies and practically no pathological lesions, at least none visible to the naked

eye, suffer intensely from some one or more of these nervous symptoms. In this class of older people, where the lesions have developed slowly and without marked mechanical irritation from external causes or without circulatory disturbances, it may happen that these patients are not neurotic and that they will never develop any of the symptoms such as have been outlined above. It would then seem as if nasal symptoms were not so much caused by pathological conditions alone as by associated conditions of disturbed circulation and nerve irritation. And if these two conditions, together with absence of the discharge, are lacking in our patients, we may have marked pathological lesions developed without a single symptom.

This paper to-night has been upon an unimportant subject; its results are negative, but it has directed our thoughts to a class of cases which are found very frequently in the aged, and probably, upon more careful inspection, would be found quite often in younger people. It has also emphasized the important fact that symptoms of discharge, pain, or obstruction, are not in proportion to the amount of lesion present, but in certain cases may be entirely absent in the presence of well-developed lesions. It also serves to draw our attention to the fact that chronic congestive interference with circulation, lymphatic obstruction, and neurotic temperament, are very important elements in nasal cases, and that the cure of the patients who suffer from nasal symptoms often will not result from mere mechanical removal of the lesions present in the nose.

WHAT ROUTINE SHALL WE ADOPT IN EXAMINING THE EYE MUSCLES?*

BY ALEXANDER DUANE, M. D.,

NEW YORK.

It is not my purpose in this paper to attempt to discuss all or even a majority of the methods used in measuring anomalies of the eye muscles, but simply to indicate the methods that I myself have worked up to by a gradual experience and at present consider the most satisfactory. In a presentation of this sort nothing very novel can be expected, and I must crave your patience if, in describing my own procedures, I go over ground already well trodden and descent upon methods that everybody employs. Still, there is no unanimity of opinion as to which, even of the familiar methods, is sufficient for an ordinary examination, or as to how they compare with each other in value. It is in order to elicit a general expression of opinion upon this important topic that I present my own views and detail my own practice. I will, then, consider briefly:

1. The routine that I adopt in ordinary cases.
2. The deductions that I have gathered with regard to the relative reliability and availability of the several tests.

*Read before the Ophthalmological Section of the New York Academy of Medicine, April 15, 1901.

3. The way in which the tests are employed specifically in operations.

Routine of Examination.—After making a cursory inspection of the patient to detect the presence of any obvious anomaly, I direct his attention to a cardboard sheet, a foot or more square, hanging on the opposite wall of the room. In the centre of this sheet is a round black spot, one inch in diameter. I cover the left eye with a screen, and, first making sure that he is fixing the spot with his right eye, I pass the screen quickly from the left eye to the right. In so doing I watch for any deviation taking place in either eye, and at the same time ask the patient if he notices any movement of the spot. I then place prisms, appropriately directed,* before the eyes, gradually increasing their strength until there is no longer any deflection behind the screen. This neutralizing prism will indicate the amount and character of the deviation as measured by the *screen test*. The same prism may also abolish the apparent movement of the spot, perceived by the patient. If not, I change the prism until this movement is absolutely nil, and thus measure the amount and character of the deviation by the *parallax test*.

If there is any noticeable deflection behind the screen, I then apply the *screen test in a second way* or by *binocular uncovering*. This well-known procedure consists in covering the left eye and then uncovering both eyes and noticing the movement that takes place. If, on thus uncovering the left eye, the right eye remains steady and the left moves into position, I know that the patient has binocular fixation, and that the deflection was a heterophoria and not a squint. If, however, the right eye should move out of its position and the left eye should move into place, I know that there is a squint and that the left is the fixing eye. If neither eye moves, I know that there is a squint and that the right is the fixing eye. By repeating this experiment with each eye alternately I can tell whether there is an habitual binocular fixation, an alternating fixation, or a unioocular squint. The diagnosis between the three may be conveniently formulated as follows:

1. If in binocular uncovering *but one eye moves*, we have heterophoria and not squint.

2. If either *both eyes move* or, in spite of there being an evident deviation, *both eyes remain steady*, there is a squint.

3. In the latter case, if, when the left eye is uncovered, the eyes behave in the same way as they do when the right eye is uncovered (both alike moving or both alike remaining steady, no matter which eye is uncovered), the squint is *alternating*.

4. If, when one eye (for instance, the right) is uncovered, both eyes move, and when the other eye (in this case the left) is uncovered, both eyes remain steady, the squint is *unioocular* (confined in this case to the left eye).

I next employ the *Maddox rod* in the usual way, test

*I. e., base in for an outward deviation, base out for an inward deviation, base up or down for a vertical deviation.

ing first for vertical and next for lateral deviations. For this, of course, I use a light as a test object. Next I employ the *phorometer* (Stevens's model), and again first for vertical and then for lateral deviations.

With the phorometer and Maddox tests I find, like other experimenters, that I get more accurate results if, as the patient is looking through the apparatus, I cover one eye for a few moments, then suddenly withdraw the cover and make the test before the patient has had a chance to fuse or separate the double images.

The phorometer being still in position, I now use it in *testing at near points*, the test object in this case being a fine dot on a rather large card. Any object with lines in it I regard as vitiating the accuracy of the test.

Using the same test object, I then make the *near test with the screen and parallax* just as for distance.

I next ascertain the *convergence near-point*, using any fine object and bringing it up close to the eyes until the patient can no longer converge upon it, and then measuring or estimating the distance of the object from the root of the nose.

Then I determine the *prism-divergence* (abduction) and the *prism-convergence* (adduction) in the usual way with prisms, held respectively base in and base out. In testing the prism-convergence it is a good plan to notice whether the accommodation is called into play as the patient converges. This can be ascertained if we use the ordinary trial card as a test object and observe how much the patient's vision is blurred by the progressive addition of prisms base out.

Lastly, I determine the *field of binocular single vision*. This I do as follows: I place a red glass before the patient's right eye, and, standing at a distance of four feet, carry a candle so as to make it skirt successively all the outlying parts of the field of fixation. That is, I carry it first to the extreme right, then rather quickly back again to the middle line and on to the extreme left, then up (*i. e.*, to the up-and-left position), then back to the middle line (straight-up position) and on to the right (up-and-right position), then down to the horizontal plane, and then below it, so as to skirt the lower field in the same way as the upper. In doing this, I note whether the patient gets diplopia in any part of the field, how great the diplopia is, and in what direction it tends to increase; and at the same time I watch to see whether the excursions of the eyes appear normal in all directions, or whether either eye lags behind in its motions anywhere.

It may often happen that the patient cannot be got to recognize diplopia, although there is an evident deviation present. I then determine the *field of binocular single vision by the screen test*, *i. e.*, I estimate the deviation behind the screen, first in the primary position, and afterward in the different portions of the field of fixation, and thus ascertain how and where the deviation increases and whether the patient has binocular fixation everywhere.

This routine, which is sufficient for ordinary cases, occupies from ten to fifteen minutes. In special cases I employ two other accessory tests:

1. I determine the *declination* with the Maddox rod clinometer, elsewhere described.* In default of this, a Maddox rod, set in a trial frame, will answer as well.

2. I determine the *field of fixation*. In doing this I use a perimeter and employ as a test object two fine dots set very close together. With such an object the patient, unless fixing sharply, sees the two dots run together. If he sees them separate, it is proof that he is still fixing correctly upon them. This test object I find more satisfactory, particularly in the case of children, than the small letters that are generally employed for the purpose.

The tests recommended and the order in which they are used may be recapitulated as follows:

A.—We determine the deviation for distance by

(1) The screen and (2) the parallax simultaneously.

(3) The Maddox rod.

(4) The phorometer.

B.—We determine the deviation for near by

(5) The phorometer.

(6) The screen and (7) the parallax simultaneously.

C.—We next measure

(8) The convergence near-point.

(9) The prism-divergence (abduction).

(10) The prism-convergence (adduction).

(11) The field of binocular fixation and the excursions of the eyes.

D.—In special cases we ascertain

(12) The declination by the clinometer.

(13) The field of fixation by the perimeter.

It goes without saying that in making all the foregoing tests, I note carefully *the conditions under which they are done*—*i. e.*, whether made with or without correction of the refraction and whether or not under the influence of homatropine.

Reliability of the Various Tests.—Of the four tests, the screen, the parallax, the Maddox rod, and the phorometer, employed in determining the balance of the eye muscles, I regard the *screen test* as by far the most reliable. It is also almost universally applicable, being especially available in the case of children and also with those who no longer have binocular vision. It is fairly accurate, too. The deviation shown by it, if measured with prisms, can be estimated to within 2°.

Next in point of reliability I regard the *parallax test*. It is usually available when the screen test is, and it is extremely precise, deflections of the smallest fraction of a degree being sharply made out.

The *Maddox rod*, although a very useful accessory test, has not in my hands proved as reliable nor as accurate as the others. It is rather apt to indicate an ex-

*In a paper presented to the Third Pan-American Medical Congress, February, 1901.

cess of deviation, especially in esophoria. Many patients, on the other hand, have a strong tendency to unite the line of light and the flame, insomuch that some will always see them united even with prisms of high degree. This source of inaccuracy may be partially avoided by making the test in the way already mentioned, *i. e.*, by screening one eye for a few moments, then suddenly removing the screen and determining the relations of the flame and the line of light immediately, before the patient has had a chance to unite them.

In estimating vertical deviations I find the Maddox rod usually very accurate.

The *phorometer* is also a very useful accessory, but in many instances, particularly at near points, indicates an excess of deviation.

However determined—whether by the phorometer, Maddox rod, screen, or parallax—the deviation should be ascertained *both for distance and for near vision*. This I regard as of essential importance. A comparison of the findings for distance and for near vision will show whether the deviation increases or diminishes as the test object approaches the eyes—an important factor in distinguishing divergence and convergence anomalies—and in the case of squint will show whether the latter is periodic or not.

Also of considerable value as bearing on the diagnosis is the determination of the *convergence near-point*. This is of essential importance in distinguishing a true convergence insufficiency from an exophoria or divergent squint due to a divergence anomaly or due to a simple disuse of the converging power such as we may find in the early stages of an accommodative exophoria. Furthermore, it is of great importance in determining whether in a given case of exophoria or divergent squint we are likely to secure a favorable result by a simple tenotomy of the externi or shall have to do an advancement of the interni. Finally, it is a test that should never be neglected in gauging the effect of an operation on the interni, since tenotomy of the latter should never be carried so far as to make the convergence near-point recede unduly.

Just as the convergence near-point shows the absolute maximum of convergence of which the patient is capable, so the *prism-divergence (abduction)* gives us his absolute maximum of diverging power. Its actual amount in a given case will often indicate whether we are dealing with a divergence or a convergence anomaly. Hence I regard its determination as a very important feature of the examination.

I would not say as much for the *relationship between the abduction and adduction*, upon which some have laid so much stress. This relationship varies so much in the same individual from time to time that I cannot regard it as of importance.

The prism-divergence, in fact, is an absolute maximum, the prism-convergence usually a small and varying fraction of a maximum.

It seems to me unreasonable to institute any comparison between two magnitudes so constituted.

Nor can I find that much importance attaches to the determination of the *abduction at near points*. This also varies so much in the same individual that I cannot see what deductions can reasonably be drawn from its determination, except in special cases.

The estimate of the *field of binocular single vision*, if carefully made, I regard as very important. When a patient has actual binocular single vision he will see a parti-colored light; when he has unocular vision he will see one light, red or yellow, as the case may be. When he has true diplopia he will see two lights, one red, the other yellow.

By drawing the patient's attention to this point we can in almost all cases decide the kind of vision that he has, and determine accurately the presence and amount of diplopia. And by observing how and where this diplopia increases we can ascertain what muscle or muscles are affected and to what extent. On the other hand, the presence of binocular single vision in the whole field of fixation necessarily excludes a real insufficiency of any ocular muscle.

Hence, by thus determining the field of binocular single vision either with the candle or with the screen test, and by noting at the same time the limits of excursion of the eyes, we can in general distinguish an insufficiency of the interni or externi *per se* from an esophoria or exophoria due to a divergence or convergence anomaly.

I have not been led to attach so much importance to the determination of the *field of fixation* by the perimeter. The limits of excursion for each eye, when examined separately, vary considerably even in the same patient. Again, it is only when the eyes are under the impulse afforded by binocular vision that they move in their natural way, and it is not infrequent to find that when the examination of the field of fixation shows no great limitation there is yet a decided restriction of the excursion of one eye as compared with the other when tested with the red glass and the candle. Nevertheless, in doubtful cases the mapping out of the field of fixation may be of service in showing whether a given deviation is due to a muscular over-action or a muscular insufficiency.

Application of the Tests in Operations.—It is my invariable practice to test a patient carefully, not only just before an operation, but also several times during its performance and immediately after its close. For this purpose I usually rely upon the screen and the parallax tests, at times also using the Maddox rod. If a patient shows diplopia, I also measure its amount, but the measurement of the diplopia affords much less certain results than the test by screen and parallax. These latter tests require no apparatus beyond a few prisms, and even these may be dispensed with, except toward the close of an operation, when we wish our measurements to be quite precise. Furthermore, they can be applied in a moment and without changing the position of the patient, and

they are not confusing to him, so that we are not so likely to have any error owing to his misinterpretation or misstatement of what he sees.

I habitually stop two or three times at least during the course of an operation to make these tests and ascertain by them whether I have gone far enough. If not, I continue, gauging the extent of my next step by the result of the test last made, and pausing only when actual measurement shows me either that I have attained just the effect that I desired to secure or that I have gone as far as safety allows. This method of operating is not brilliant and it is tedious, but it certainly affords satisfactory results and is safe.

49 EAST THIRTIETH STREET.

OSSICULECTOMY

FOR CHRONIC SUPPURATIVE OTITIS MEDIA.*

By J. A. STUCKY, M. D.,

LEXINGTON, KY.

ON account of the peculiar anatomical topography of the middle ear and its very intimate relation to the most delicate and vital portions of the body, any disease to which it is subject becomes of more than passing interest. In this brief paper emphasis is placed upon the word "chronic," and the object is to call attention to a neglected conservative surgical procedure which the writer believes to be of very great utility in bringing about permanent relief of one of the most frequent and obstinate diseases with which the aurist has to deal. The battle confronting him is to secure free and uninterrupted drainage, and the victory is all but won when this is accomplished.

The entire anatomical arrangement of the middle ear favors pathological conditions. The drum membrane is tough, fibrous, and firmly attached to its bony ring. The ossicular chain is irregular and tightly held together, and readily catches and retains suppurative exudation. The cavity itself is crooked and not adapted to drainage. These facts we all not only understand, but fully appreciate, and because of the great importance of this cavity and its close relation to the brain, much time, study, and scientific research have been given by the best minds of our profession to the solution of the problem, What is best to be done for chronic suppurative otitis media? Shall we be radical or conservative? This last question is not for discussion at this time, though a suggestion of caution will not be out of place, lest in our enthusiasm or brilliant surgery and its results we do the radical and extensive operation when possibly less heroic and more conservative methods would have accomplished the same result.

In 1896 the writer published the results of removing

necrosed ossicles in fourteen cases, and to-day fifteen are added, making a total of twenty-nine. The results justify the methods used.

Chronic suppuration leads inevitably to necrosis sooner or later, and the fact must not be lost sight of that dead bone in the tympanic cavity, more than in any other part of the body, is apt to produce disastrous results. The method of operation for removal of the drum membrane and the ossicles is so accurately described in the text-books and so thoroughly known that no reference to technique is needed. In only two of the twenty-nine cases of operation was the stapes removed. In none had the disease existed less than seven years.

Given a case of chronic suppuration which has existed for years, if dirty granulation, blocking a perforation through Shrapnell's membrane, the drum remnant soggy, is found, and the probe reveals roughness indicative of necrosis of the malleus or anvil, or both, the hands of the surgeon are tied until the necrotic ossicles and part or all of the tympanic membrane are removed and the cavity thoroughly curetted. When this is done, and the anterior attic wall is removed, we have the free drainage, and can make remedial applications, which could not be done otherwise. The writer would not be understood as advocating this procedure in every case of chronic suppuration, for many of these require the radical operation. In all cases in which there are a large or even medium-sized canal and unmistakable evidence of chronic disease of the attic with perforation of Shrapnell's membrane and all the conditions attending suppuration (with necrosis usually), removal of the ossicles, a portion or all of the anterior attic wall, and remnants of the drum membrane I believe to be the most conservative and satisfactory procedure.

The treatment thus briefly outlined is ably championed by Allport, of Chicago, and Lake, of London. Others eminent in our ranks go a step further and advocate the radical surgical treatment. The writer believes the former should always be resorted to first, because:

1. It gives free drainage.
2. It affords an opportunity to successfully combat the suppurative process.
3. It is free from danger to life and health.
4. In a large percentage of cases the disease is arrested, the hearing improved, only rarely made worse.
5. There is no deformity or scar.

The dry treatment is inadequate, because of the débris collecting around the ossicles. Conservative surgery is justified, because this hindrance is removed.

Chronic suppurative cases with cholesteatoma or necrotic destruction of the posterior superior wall of the canal are not benefited by anything short of the radical operation. Within the last three months I have been called upon to do the radical operation in two cases of acute inflammatory exacerbations of chronic middle-ear suppuration, one of which had existed for nineteen years. The son of a physician, the patient had been treated at

*Read before the Western Section of the American Laryngological, Rhinological, and Otological Society, in Chicago, December 28, 1900.

short intervals during the entire time, and had been advised to submit to a radical operation, but had declined.

When I saw him he had been suffering great pain for several days. The usual remedies, the hot douche, the hot-water bag, and opiates, had given only partial relief, and he was ready now to submit to any surgical treatment that promised relief. The mastoid was swollen and tender, the pulse quick, and the temperature 102.2° F. Inspection with the speculum through an unusually large canal showed remnants of the perforated soggy drumhead and the cavity filled with granulations. I advised the intratympanic operation, suggesting that if that did not relieve all the symptoms in a few hours the radical procedure could easily be resorted to. To this he consented. The granulations and débris were cleaned out, parts of the malleus and incus were found, and the attic and the walls of the cavity were curetted. The patient made a rapid, uneventful, and satisfactory recovery in less time than usual after the radical operation. He feels and hears better than for a long time. This seems a fair illustration.

In the cases of operation by this method—twenty-four—the discharge ceased in a few weeks and the cavity was lined with a vascular fibrous membrane. In eighteen there was no improvement in hearing, but all suppuration ceased and the other symptoms were relieved. In one, in which the stapes was removed, the injury to the facial nerve resulted in paralysis, but this entirely disappeared in nine weeks.

THE IMPORTANCE OF THE EARLY RECOGNITION OF ABDOMINAL INFECTIONS.

By W. D. HAMILTON, M. D.,

COLUMBUS, OHIO.

A LARGE part of the surgeon's work to-day has to do with conditions which were either pathologically unknown or "inoperable" twenty years ago. These advances bring greater responsibility to the physician of to-day. He should be cognizant of those conditions which may call for surgery.

Abdominal physical diagnosis is added to his former duties. The general practitioner is not expected to be an expert in the recognition of these pathological conditions. Lawson Tait said to the members of the Surgical Section of the British Medical Association at Leeds, in Yorkshire, some years ago, that twenty per cent. of abdominal diagnoses were wrong, including his own. This certainly suggests an attitude of extreme modesty on the part of those who do abdominal surgery. The fact remains, however, that early, thoughtful, searching examination of the abdomen should be made when one is called to a case having such possibilities. An inflamed appendix, a perforating gastric or intestinal ulcer, a leaking gall-bladder, extravasation about the kidney, ureter, or bile duct, a subdiaphragmatic abscess, a suppurating

extra-uterine pregnancy, are some of the conditions that may demand his attention. On the other hand, a pelvic abscess, a localized tuberculous focus, any of those traumatism to the abdominal contents, or anything which may cause peritonitis, thereby jeopardizing the patient's life, could properly be considered in this category.

A retrospect of the last few years will, in the writer's mind, bring out clearly this fact with reference to abdominal infections which required operative interference. When the patient has died after an operation, it has generally been apparent that an earlier use of the knife would have offered a better chance of recovery. It would be unjust to assume that the attending physician is always to blame, and the writer accepts his share of the censure; occasionally a surgical consultation or an operation promptly proposed has been declined by the patient or the relatives.

It is not the intention of the writer to leave the inference that every patient should at once be cut who has an intra-abdominal infection. The idea to be conveyed is this, that the history of the patient, palpation, percussion, digital examination, uranalysis, and, if available, a blood examination, in fact, all those means of investigation which could be employed, should be *used early*. A prompt diagnosis is half the battle in these cases. How simple the management of a case of appendicitis that is from twelve to twenty-four hours old can often be made by an operation! When we are called to a case in which there is ground for the suspicion of an intra-abdominal infection, the question to be raised is this: Is it medical or surgical? If the latter, accept or dismiss the idea of operative intervention at the earliest time practicable. It is the object of this paper to minimize the number of those forlorn cases which too often come to the surgeon in which, by delay, the patient has been irreparably overwhelmed by bacterial invasion of the abdomen. In such cases too often an operation cannot be done. If it is tried, it will in all probability simply convert an operation into an autopsy. In other words, as has been said by some writer, the resources of surgery are not often successful when practised on the dying. The writer believes that in doubtful cases there is less risk in an ably conducted exploration than in delay and fruitless speculation.

Within the past year the writer has been told by a general practitioner from Southern Ohio that the last patient (one with suppurating appendicitis, a stout man) was the twentieth one with appendicular infection whom he or his partner had brought under operative treatment; and that all the cases had terminated favorably. This is a commentary on what *prompt diagnosis* on the part of the attending physician may accomplish in the relief of this condition.

The proper attitude to abdominal infections may be summarized in the words of the clever Irishman, Sir Boyle Roche, that "the best way to avoid danger is to meet it plump!"

ANTISTREPTOCOCCUS SERUM IN TWO CASES OF PUERPERAL SEPTIC INFECTION.

By A. J. PRIMROSE, M. D.,

NEW YORK.

I AM led to report these cases from the prompt subsidence of septic symptoms following the use of antistreptococcus serum. The cases are briefly as follows:

Mrs. M., thirty-five years of age; has one grown child and has had several subsequent miscarriages. Chronic endometritis, delivered of a nine-months child. Forceps were used and an intra-uterine douche of bichloride given.

On the evening of the third day the patient had a chill, and the temperature rose to 102° F. She complained of severe headache and the lochia was slight and fœtid. An intra-uterine douche of bichloride was given.

Morning of fourth day, patient had a chill, severe headache, the lochia were foul-smelling, temperature 104° F. She was curetted by a consulting physician, but only clot-shreds were removed. An intra-uterine injection of boiled water was given. She had another chill. In the evening the temperature was 103° F. Ten cubic centimetres of antistreptococcus serum (Board of Health) were injected into the right leg. Six hours later the temperature was 102.5° F. Ten cubic centimetres of antistreptococcus serum were injected in left leg.

Morning of fifth day, temperature 101½° F. An antiseptic intra-uterine douche was given. Noon temperature, 102° F. Ten cubic centimetres of antistreptococcus serum injected in abdomen. Evening temperature, 101.5° F.

Morning of sixth day, temperature 101° F. Seventh day, temperature normal; slight increase of watery lochia followed the douches. Three days later patches of erythema appeared over sites of injections. One week later she complained of joint pains and stiffness, lasting a day or so. Patient convalescing.

Mrs. O., twenty-five years of age; delivered of first child at nine months. Got out of bed on the fifth day; ate a heavy meal on the sixth day. This was followed by a chill and severe headache; the temperature was not taken.

When seen on the evening of the eighth day, she was flushed and complaining of severe headache. Temperature, 103° F.; lochia very scanty and somewhat fœtid. A noticeable swelling on the left side of the cervix. The dull curette was used, but only a few clot-shreds were removed. An antiseptic intra-uterine douche was given. Temperature, later in evening, 103° F. Ten cubic centimetres of antistreptococcus serum were injected in left leg.

Morning of ninth day, temperature 101.5° F. The antiseptic intra-uterine douche repeated. Evening temperature, 101.5° F. Patient feeling well.

Noon of the tenth day, temperature 104° F.; no chill observed. Intra-uterine douche given, and ten cubic centimetres of antistreptococcus serum injected in abdomen. Six hours later the temperature was 103° F.; ten cubic centimetres of antistreptococcus serum injected in right leg.

Eleventh day, temperature normal; feeling well. Thirteenth day, the patient sat up several hours with no ill effects.

Several days later she complained of pain and stiff-

ness of the knee and hip joints. Temperature for a few hours rose to 102° F. The symptoms subsided after a few doses of sodium salicylate. The swelling about the cervix uteri was no longer noticeable.

 Correspondence.

LETTER FROM TORONTO.

A Toronto Physician Knighted.—The Victorian Order of Nurses.—The Canadian Nurses' Association.—A Testimonial to Sir William Hingston.—Dalhousie University.—Bishop's Medical Faculty.—The Montreal Dispensary.

TORONTO, May 18, 1901.

DR. GEORGE STIRLING RYERSON has been gazetted a Knight of Grace of the Order of St. John of Jerusalem in England, in recognition of his distinguished services in connection with Red Cross work in South Africa. Lord Roberts has spoken in the highest terms of his services, and Lord Wantage, as chairman of the Red Cross Society, has written Dr. Ryerson along the same lines. Surgeon-General W. D. Wilson, principal medical officer of the army in South Africa, has also written Colonel Ryerson an appropriate letter of thanks, while the Red Cross Council, at its recent meeting in Toronto, also adopted a resolution of thanks to Dr. Ryerson and further voted \$500 toward defraying his expenses. The profession in Toronto is distinctly pleased at the recognition of Dr. Ryerson's services.

The local branch of the Victorian Order of Nurses in Canada held its annual meeting in Toronto not long since. Lady Minto was present from Ottawa and addressed the meeting on her project of cottage hospitals for the Canadian Northwest Territories. Toward this work the Dominion government has contributed \$6,000 and Sir William Macdonald, of Montreal, \$3,000, while recent contributions to her fund have amounted to from \$4,000 to \$6,000 more. The annual report of the superintendent of the Toronto branch was submitted to the meeting. It showed that during the past year 249 patients had been cared for, with a total of 4,323 visits paid. There had been added to the list thirty-eight Toronto physicians who had employed these nurses during the year. Out of the 249 patients, only sixteen had been lost by death. The fees collected for the year were \$472. Two nurses have been sent out to Cape Breton and Quebec. Dr. James Thorburn, the president, delivered an address on the working of the order in Toronto.

The Canadian Nurses' Association is seeking incorporation from the Dominion Parliament. Before the House Private Bills Committee it experienced a good deal of opposition, the chief objection being to the nurses' themselves passing on applicants. The intention of the bill is not to discriminate against the smaller hospitals. The association will be given power to adopt its own

rules and regulations, while the object of the measure is purely educational and designed to raise the status of nurses in Canada. The ladies named as incorporators represent the best hospitals all over the Dominion. The conditions of qualification as they now stand propose to admit all nurses who have graduated from any hospital approved by the association, and the bill provides that a majority of the advisory board shall consist of medical men. A proposal to hold the bill back for another session was defeated.

Sir William Hingston was the recipient of distinguished honors on the afternoon of the 6th of May from his confrères at the Hôtel Dieu, Montreal, as well as from the Sisters, students, and patients of the institution. The occasion was the celebration of the fortieth anniversary of Sir William's connection with this hospital as a surgeon, and the opportunity was seized to show the appreciation of his services by the staff and Sisters of the hospital. Archbishop Bruchesi began the ceremonies by the celebration of mass in the chapel, after which the surgeons of the Hôtel Dieu presented Sir William with an address and an urn of great value. The gathering then repaired to one of the operating-rooms, where the medical students of Laval University had gathered. They presented their professor with an address and handed Lady Hingston a bouquet of great magnificence. The Sisters of the institution also paid their respects to Sir William and presented him with some relics which had been preserved for over two hundred years and had been brought over from France by Mlle. Mance. Dr. St.-Jacques, in the name of the patients, addressed the distinguished surgeon, thanking him for his many years of service and for the good he had accomplished for them during the forty years of his connection with the Hôtel Dieu. To all these tokens of appreciation Sir William replied feelingly, expressing special surprise at receiving thanks from the patients, when he had always been busily engaged in taking off their arms and legs or taking out their eyes. Sir William Hingston is now in his seventy-third year and is yet actively engaged in his surgical work. His son, Dr. Donald Hingston, has recently received the appointment of superintendent of the Hôtel Dieu, succeeding Dr. St.-Jacques, who has resigned.

At the recent convocation exercises of Dalhousie University, Halifax, some twelve or thirteen persons received their degrees, one being a lady, the first who has graduated in medicine from that university.

A number of changes have been made in the teaching staff of Bishop's Medical Faculty, Montreal. Dr. F. W. Campbell, the dean, will in future give a special course of lectures on insurance law, in addition to his regular lectures in medicine and neurology. He will have associated with him as professor of medicine Dr. J. B. McConnell as vice-dean. The chair of medicine will be further assisted by Dr. W. E. Deeks, lecturer on internal medicine; Dr. A. J. Richer, and Dr. W. Grant Stewart. Dr. James Perrigo, professor of gynecology, will have

associated with him Dr. A. Laphorn Smith, who remains also professor of clinical gynecology. Dr. H. L. Reddy and Dr. William Burnett retain their professorships in connection with that department. Dr. George T. Ross, professor of laryngology and rhinology, who up to the present time has been registrar of the faculty, has been replaced as such by Dr. James M. Jack, a new member of the staff, who will also lecture on dermatology. The chair of surgery is to be occupied by Dr. F. R. England, with whom will be associated as lecturers Dr. F. J. Hackett and Dr. Rollo Campbell, and as instructors Dr. George Fisk and Dr. Herbert Tatley. Another addition to the teaching staff is Dr. Louis Laberge, the city medical health officer, who replaces Dr. Richer as lecturer in hygiene. Dr. W. G. Reilly has been appointed to the chair of anatomy. Dr. Robert Wilson will hold the chair of materia medica and therapeutics.

The annual meeting of the Montreal Dispensary was held last week, when the reports which were submitted showed a very successful year. The total number of applications for advice and treatment by the sick poor numbered 16,918. During the past two months, Dr. A. E. Vipond has had charge of a special department for the diseases of children, with a very successful clinic attached to it. The treasurer's report showed that the receipts, including a balance from the previous year of \$3,545, had been \$6,501, and the disbursements had amounted to \$2,912, leaving a favorable balance of \$3,589. Dr. H. B. Carmichael was elected honorary secretary. The consulting physicians are Dr. W. Wright, Sir William Hingston, Dr. Robert Craik, Dr. F. W. Campbell, Dr. G. P. Girdwood, Dr. George Wilkins, Dr. A. D. Blackader, Dr. J. B. McConnell, Dr. W. Gardner, Dr. F. J. Shepherd, Dr. A. Laphorn Smith, Dr. G. T. Ross, Dr. F. M. R. Spendlove, Dr. Rollo Campbell, Dr. J. W. Stirling, Dr. E. H. P. Blackader, and Dr. A. E. Orr. The attending physicians are Dr. H. Tatley, Dr. H. B. Carmichael, Dr. G. A. Brown, Dr. R. A. Westley, Dr. A. A. Robertson, and Dr. A. T. Bazin. The assistant physicians are Dr. J. L. Day, Dr. A. Mackenzie Forbes, Dr. J. J. Ross, Dr. W. B. Howell, and Dr. Walter Fisk.

Therapeutical Notes.

Palatable Effervescent Quinine.—The *Journal of Tropical Medicine* for May 1st quotes the following from the *Therapist*:

℞ Quinine sulphate 1 drachm;
Citric acid 2½ drachms;
Syrup of orange peel 15 minims;
Syrup 15 “
Distilled water, enough to make . . 5 drachms.

M.

Ten or twenty drops to be added to two ounces of water containing five or six grains of sodium bicarbonate. Ten drops of the mixture contains about one grain of quinine.

Cochineal in the Treatment of Whooping-cough.—

In the old days when nitric acid, very much diluted, was largely used in the treatment of whooping-cough, tincture of cochineal was generally added, chiefly to give the medicine an attractive color, but partly also because it was thought to add to the remedial effect. Naegeli (cited in the *Gazette hebdomadaire de médecine et de chirurgie* for April 18th) seems to credit cochineal with medicinal virtues in whooping-cough. He uses the following formula:

- ℞ Powdered cochineal. . . $\frac{3}{4}$ of a grain to 3 grains;
- Ammonium carbonate. 15 to 30 “
- Syrup of bitter-orange peel. 2 ounces;
- Distilled water. 10 “

M. S.
A coffeespoonful every two hours.

A Lotion for Freckles.—*Pratica del medico* for November, 1900, gives the following:

- ℞ Corrosive sublimate. 15 grains;
- Zinc sulphate. 30 “
- Lead water. 30 minims;
- Rose water. 8 ounces.

M.
For outward application only.

The following is also said to have given good results:

- ℞ Valerianate of amyl. 3 drops;
- Sulphuric ether. $\frac{1}{4}$ “

M.
For one capsule. Six capsules, two at a time, to be taken half hourly.

The following suppositories are given by the author:

- ℞ Extract of belladonna, } of each. . . $\frac{1}{3}$ of a grain;
- Extract of opium, }
Cacao butter. 30 grains.

M.
For one suppository. One hourly till the symptoms subside, but not more than five must be used in the twenty-four hours.

For Hepatic Colic.—M. Mesnard (*Presse médicale*, August, 1900; *Union médicale du Canada*, December, 1900) recommends a combination of benzoate and salicylate of sodium:

- ℞ Sodium benzoate. 75 grains;
- Sodium salicylate. 150 “

M.
Divide into fifteen wafers; three daily at meal times.

For Lepra, Psoriasis, and Lupus.—*Progrès médical* for April 27th ascribes the following to Bocquillon-imousin:

- ℞ Gynocardic acid. 12 grains;
- Chaulmoogra oil. 150 “
- Vaseline. 300 “
- Paraffin. 75 “

M.
For local application.

Serious Diarrhœa of Nurslings.—The *Journal of Tropical Medicine* for May 1st gives the following:

- ℞ Atropine sulphate. $\frac{1}{10}$ th of a grain;
- Distilled water. 450 minims.

M.
From one to three drops may be given, but the general condition must be closely watched, and three drops must not be exceeded.

For Uterine Vomiting.—According to Lutaud (*Consultations upon the Diseases of Women; Journal des praticiens*, May 4th), the following is considered the best formula for the use of cocaine in these conditions:

- ℞ Cocaine hydrochloride. $1\frac{1}{2}$ grains;
- Antipyrine. 15 “
- Distilled water. 1,500 minims.

M.
To be taken in coffee-spoonful doses every half hour until the vomiting ceases. Occasionally the following more concentrated solution may be called for:

- ℞ Cocaine hydrochloride. $7\frac{1}{2}$ grains;
- Distilled water. 450 minims.

M.
Ten drops to be taken and repeated at the end of an hour, then after the lapse of three hours if there has been no result. Then give from three to four drops before meals.

In case of pregnancy or acute metritis, apply to the cervix a tampon with the following ointment:

- ℞ Cocaine hydrochloride. 15 grains;
- Extract of belladonna. $3\frac{3}{4}$ “
- Vaseline. 150 “

M.
Local applications or slight digital dilatation, as recommended by Copeman, often cause the vomiting of pregnancy to cease. Routh's procedure, paintings of tincture of iodine, is also frequently successful.

In vomitings of less intensity, with nausea, the following may be used:

- ℞ Tincture of iodine, } equal parts.
- Chloroform, }

M.
Five drops, morning and evening, at meal times, in a little water.

Menthol may be prescribed as follows:
℞ Menthol. 15 grains;

- Alcohol. 300 minims;
- Syrup. 450 “

M.
A coffee-spoonful every hour.

At times it is necessary to have recourse to rectal alimentation, and generally a supporting medication is necessary, *e. g.*, that of Crocq:

- ℞ Sodium phosphate. 15 grains;
- Distilled water. 150 minims;

M.
A Pravaz syringeful morning and evening.
Injections of artificial serum may often be employed with advantage.

Chrysarobin in Hæmorrhoids.—Pounne (*Journal des praticiens; Revue médicale de Normandie*, April 25th) has successfully used chrysarobin, in suppository or ointment, in bleeding hæmorrhoids, in the following combinations:

- ℞ Chrysarobin. $1\frac{1}{4}$ grain;
- Iodoform. $\frac{3}{10}$ ths of a grain;
- Extract of belladonna. $\frac{1}{65}$ th of a grain;
- Cacao butter. 30 grains.

M.
For one suppository. Two or three to be used daily.

- ℞ Chrysarobin. $22\frac{1}{2}$ grains;
- Iodoform. $7\frac{1}{2}$ “
- Extract of belladonna. 15 “
- Vaseline. 300 “

M. Fiat unguentum.

THE NEW YORK MEDICAL JOURNAL,
62-68 West Broadway.

NEW YORK, SATURDAY, MAY 25, 1901.

THE PROPOSED REORGANIZATION OF THE AMERICAN MEDICAL ASSOCIATION.

A COMMITTEE consisting of Dr. J. N. McCormack, of Bowling Green, Kentucky; Dr. P. Maxwell Foshay, of Cleveland, and Dr. George H. Simmons, of Chicago, is to present at the St. Paul meeting a formal report embodying a plan for the reorganization of the American Medical Association. The committee's preliminary report is before us, in the shape of advance sheets of the association's *Journal*. In a footnote we find this statement: "A decision as to one or two details has not yet been reached, although practically all that is herewith submitted is approved by the committee." We may expect, therefore, that in its final form the plan reported will not differ in any important feature from what is set forth in the preliminary report, and we are glad to be thus assured of the committee's virtual unanimity. It is within our own knowledge that the individual members of the committee, severally and among themselves and by conference with representative physicians in various parts of the country, have devoted to the elaboration of their plan an extraordinary amount of earnest work; consequently we are confident that at the approaching meeting those who may be inclined to question the expediency of one or more features of the plan will reflect that, in view of the great amount of consideration that the committee has given to those features, the great probability, amounting practically to a certainty, is that the committee's recommendations are judicious.

Fundamentally, the committee's plan provides for vesting the legislative functions of the association in a body to be known as the House of Delegates, to consist of not more than 150 members, namely, one delegate for every 500 members, or fraction of that number, of each State and Territorial organization recognized by the association, one delegate from each of the sections of the

association, to be elected like other section officers, an one delegate each from the Army Medical Corps, the Navy Medical Corps, and the Marine-Hospital Service. The members of the association are to consist of permanent, honorary, and associate members, in addition to the delegates. All officers of the association are to be elected by the House of Delegates, but no delegate shall be eligible. No person shall be elected a member of the House of Delegates who has not been a permanent member of the association for two years. Nobody shall be elected to any office unless he is present at the annual meeting at which the election occurs. This curtailment of the legislative and electoral body, it will be seen, is in complete accord with the leading suggestion which was made in our issue for April 20th, in an article entitled *The Growth of the American Medical Association*. We do not see how the committee could have failed to take the view that it has taken, and we believe that the association could in no way more strengthen itself than by adopting the recommendations embodied in the report. We are quite prepared for some delay in carrying them into effect, but we shall be much disappointed if the St. Paul meeting does not take the necessary steps to insure their early enactment. If the report fails of adoption it will be due, in our opinion, to the fact that the present organization is unwieldy even to the degree of making practically impossible to distinguish delegates from persons who, although having no right to vote, are almost sure to make themselves heard and felt as voters. By any means, let the report be adopted.

A GREETING TO THE NEW GRADUATE.

At this season of the year, when our metropolitan schools are conferring the much-coveted parchment, we are reminded of an anecdote concerning the late Dr. Alonzo Clark. When Dr. Clark, who was professor of the principles and practice of medicine in the College of Physicians and Surgeons, was in his prime, so the story goes, a member of the graduating class called on him at his house one morning for the purpose of having his chest examined, for he feared that he had incipient pulmonary disease. Having undergone the examination and received the welcome assurance that his lungs were sound, the young man asked the doctor what his fee was. "Oh, nothing, sir, nothing at all." "Why, how is that?" "Well, you know, dog doesn't eat dog." "What do you mean, sir?" "Simply that one doctor doesn't charge another doctor for professional services." "But, you know, Professor Clark, I'm not a doctor; I'm only

dent." "Very well, dog doesn't eat pup." And there was nothing for the young man to pay.

It is in this brotherly spirit, dear young graduate, that we battered old fellows welcome you to our ranks. There is no trade-unionism in medicine. Hard as we have to work for our mere living, we seek not to melt away our difficulties by setting a limit on the number of apprentices, by forbidding work after hours, or by perverting those who set a more modest value on their services than we set upon ours. No sooner do the young graduates of each year secure the right to practise than they become our brethren. What is the lot of the young physician? Almost that of a suppliant. After working hard for long, weary years—far harder and longer than either the clergyman or the lawyer—he must incur the expense and endure the waiting that are the inevitable things to even moderate progress in his practical career. To the clergyman success is apt to come all at once or not at all. The lawyer, like the doctor, generally has to wait, but he can do his waiting at a cheap rate, for, with a study-room in a decent locality, he may live in the suburbs instead of in the slums. The doctor, however, must have an expensive outfit, and in this part of the country he must almost of necessity live in the fair neighborhood in which he makes his bid for patronage.

We say this, dear youngster, not to dispirit you, but to give you a lively realization that we have all gone through the mill," and thus to let you know that an all-wise Providence has not singled you out for the dreariness of waiting unprofitably. It is because we have all had your forlorn experience that we unhesitatingly and without reservation stretch out to you the hand of welcome. This is all in the way of sentiment, as, of course, you understand; we may shortly add something in the way of advice.

SUCTION IN THE TREATMENT OF MAMMARY CANCER.

FROM Junod's boot down to the once familiar cupping-glass, with the single exception perhaps of the breast-pump, all forms of suction apparatus appear to have practically vanished from our armamentarium, although possibly the pneumatic cabinet is still employed to some extent. But this desuetude would shortly come to an end if Mr. Cecil H. Leaf, assistant surgeon to the Cancer Hospital and to the Gordon Hospital for Rectal Diseases, London, should turn out not to have been too optimistic in his scheme for the amelioration of "inoperable" cases of cancer of the breast, as set forth in the May

number of the *Edinburgh Medical Journal*. There was nothing enticing at the outset about the treatment of cancer with Chian turpentine, which excited some attention a few years ago, chiefly by reason of the eminence of its proposer; but suction, intended to prevent or restrict the central migration of the cancer germ, whatever it may be, commends itself *à priori* as at least rational.

Mr. Leaf's device differs in no essential particular from a cupping apparatus. A large hard-rubber shield is made so that its rim fits accurately on the skin around the breast, including as large an area as is practicable. In the dome of the shield there is a tap to which an ordinary air-pump can be adjusted. "The whole of the air in the apparatus can thus be thoroughly exhausted," says Mr. Leaf. This we may question while at the same time admitting that there may be effected a sufficient approach to a vacuum to make the appliance exert a very considerable suction force. He says that with a perfectly fitting instrument the suction action will last about half an hour, and, other things being equal, the more capacious the shield the longer will it continue. It does not appear from the account that the air-pump is employed again at the end of the half-hour or more; nevertheless, the author seems to think it important that the apparatus should be worn continuously for several hours, though he does not explain how it can have any beneficial effect after its suction action has once ceased. He admits that, to be really effective, the contrivance should be worn all the time, night and day, but patients will not do this, though, as a rule, they will wear it for six or seven hours, and he has one patient who will tolerate it for fifteen hours out of the twenty-four.

Mr. Leaf declares that the suction causes very little pain, but it occasions bleeding and "brings a good deal of discharge to the surface," thus in most cases relieving the pain very materially. So convinced is he of the beneficial influence of suction, and particularly of the bleeding and increased discharge caused by it, that he is considering whether in cases unaccompanied by ulceration it would not be advisable "to cause a breach of surface either by multiple punctures or by the scalpel." Even if sepsis should take place, he adds, there is every reason why, with the suction at work, there should be no absorption. He gives brief notes of three cases in which the apparatus has been used, and he is of the opinion that in all of them the march of the disease was delayed. Incidentally he makes the suggestion that the movements of the arm of the affected side should be restricted, as such movements quicken the current in the lymphatics.

Of course Mr. Leaf does not expect to cure cancer by means of suction. At the first glance, his plan for preventing or retarding its dissemination may seem to be well founded, but we fear that the mechanical difficulties in the way of any close approach to incessant suction and the inability of the sufferer to bear continuously even the degree of suction that his apparatus is capable of exerting will prove insurmountable obstacles to its successful employment. Moreover, in many cases of cancer of the breast the fatal issue has been rendered certain long before ulceration occurs.

THE MEDICAL SCHOOLS OF NEW YORK.

To those of us who remember the spirit of commercial competition which pervaded our medical schools but a few years ago their present cooperative attitude seems as wonderful as it is admirable. The spirit underlying it was well pictured by the president of Columbia University, the Hon. Seth Low, on the occasion of the recent opening of the handsome and well-equipped new building of the Medical College of Cornell University. "I never think of universities as competitors," he said, "in the business sense of that word. We are rather all allies, fighting shoulder to shoulder against ignorance and in order to spread the domain of truth. When men are striving for what they can get, I can understand a certain feeling of envy, how little admirable it may be even then, when others appear to be more fortunate than ourselves. But when men are striving for what they can give, when each is simply endeavoring to do the best service for the public that he can, it is impossible for me to understand how any one can fail to rejoice in every piece of good fortune that comes to anybody similarly engaged. . . . The College of Physicians and Surgeons, the Medical School of Columbia University, is not likely to be any the worse school because it has to maintain its reputation side by side with the Medical School of Cornell University, amply endowed as that now is. Neither is the Medical School of Cornell University likely to cherish lower standards because it has to make itself worthy to command the attendance of students in the field in which the College of Physicians and Surgeons has been so long at work. Each school will help to make and to keep the other thoroughly effective. . . . This is the spirit in which we try to do our own work, and this is the spirit in which we gladly recognize the good work done by our sister universities everywhere and in every field."

So recently as in the seventies there was not a medical school in the city of New York that dared to take the initiative in lengthening the course. Each of them felt that to take such a step would inevitably jeopardize its very existence, for they all derived their entire revenue from students' fees, and they knew that the majority of students would be driven away by any considerable augmentation of the requirements for the degree. Perhaps the College of Physicians and Surgeons was really strong enough to make the move, but was too timid to do so. When that school received its splendid endowment from Mr. Vanderbilt—the first adequate endowment of a medical school in the history of the country—the war was opened for its actual incorporation with Columbia with which it had before had little more than a nominal connection. But it was felt that wholesome competition was still desirable; hence the joy at the elevation of the College of Physicians and Surgeons was perceptibly tempered by the foreboding that the two other schools would have to go to the wall unless something unexpected happened. But the unexpected has happened, and we have still our three schools, though not precisely the same three, each with a substantial university connection. The Medical Department of the University of the City of New York and the Bellevue Hospital Medical College have become consolidated as the medical school of New York University, and the vigorous young Cornell University has established its medical school in New York.

Thus there are now in the borough of Manhattan three medical schools unexcelled anywhere in the English-speaking world, and there is an excellent school in the borough of Brooklyn. We believe there are few, if any, who really regret that the opening of the Cornell school, which admits women to its classes, led to the abandonment of the Woman's Medical College; that a admirable institution never put its own perpetuity before the welfare of the community, and its supporters recognize thoroughly that the career of women students is notably facilitated by the new order of things. Never before was New York better fitted to turn out capital physicians and surgeons, and nowhere else has such advance been made in medical education during the last twenty-five years, with one exception, that of Chicago.

QUARANTINE AND LIFE INSURANCE.

A RECENT newspaper statement was to the effect that in a city in the northern part of the State of New York a woman, having been compulsorily secluded for about six weeks on account of small-pox, notified the board

health that her policy of life insurance was likely to lapse, inasmuch as her detention was preventing her from getting the money necessary for the payment of a premium, and that the board paid the premium, holding that if the policy lapsed and the woman died, there would be a case against the city. We believe the feeling was well founded, and we hope the board's act will serve as a precedent.

A SENSIBLE FAITH-HEALING CONVICTION.

THE sentence passed by the county court judge at White Plains, and reported in our news items, upon a man who had allowed his young daughter to die from pneumonia without summoning medical aid, is an eminently just one. The man, who appeared to glory in his recalcitrance, was sentenced to a fine of five hundred dollars, and failing payment, to imprisonment at the rate of a day for each dollar until the amount was cleared off. We have at times expressed ourselves as adverse to prosecutions in cases in which it could be clearly shown that the patient himself, being of age, conscious, and in full possession of his normal faculties, preferred the services of a faith healer to those of a physician. But in the case of those dependent on others it is an entirely different matter. When a miser chooses to starve himself to death, or otherwise to court death by obstinate penurious self-abnegation, he is not usually interfered with. But let the same man neglect to provide his family, more especially young children, with food or other necessaries of life, and he is at once prosecuted for criminal neglect. Whatever may be urged, rightly or wrongly, as to a man allowing himself to die from lack of proper provision, there can be no question that he has no right to allow those dependent solely on him to do so. And, in such a case, the provision of proper therapeutic measures is an exact parallel to the provision of proper food and other necessaries. White Plains may be congratulated on the wisdom of both its jury and its judge; and we trust that the object lesson that this case affords will not be lost on juries and judges elsewhere, till fanatics are compelled to pay attention to it also.

ZOSTER ASCRIBED TO ERGOT.

THE subject of drug eruptions is always one of much interest. That unfortunately named affection known as zona or herpes zoster has in several instances been traced to the action of drugs, but not until now, if we are well informed, to that of ergot, and we must ask for some indulgence if we record our skepticism regarding a case reported by M. Druelle in the *Progrès médical* for May 4th. Some dragées of ergotine were prescribed for a syphilitic young woman who had menorrhagia. On the very next day, and in the morning at that, she complained of the neuralgic pains preliminary to the eruption which soon showed itself on the thigh. We are

hardly prepared to admit the probability of such a profound idiosyncrasy as would entail so prompt an effect, and M. Druelle himself appears not very positive about it.

TRUE AND SPURIOUS MELÆNA.

IF we accept the distinction ordinarily made between the true and the false forms of melæna—namely, that in the former the blood comes from below the cardiac orifice of the stomach, and in the latter from above that point—true melæna is shown by Swoboda (*Prager medicinische Wochenschrift*, 1900, No. 49; *Centralblatt für Gynäkologie*, April 27th) to be rare, if indeed it ever occurs. In many instances he has found the nasal mucous membrane to be the source of the hæmorrhage, but in the majority of cases purulent otitis media to be its cause. Endomeningeal hæmorrhage is rather a frequent concomitant, so that the prognosis can hardly be improved by plugging the nares.

THE OLEANDER LOUSE AS A TRANSMITTER OF MALARIA.

THE part played by insects in the transmission of diseases is meeting with constantly growing consideration. M. Vicente (*Archives générales de médecine*, March; *Gazette hebdomadaire de médecine et de chirurgie*, April 28th) thinks he has found a vehicle of malaria in the *Aspidiotus nerii*, a crustacean insect that infests the oleander. A certain family included a person who for many years had been subject to frequent malarial attacks. Some oleanders were added to the ornaments of the house, and three children promptly showed signs of malarial disease. The hæmatozoon of malaria was found on the lice parasitic on the plants.

THE NEW PRESIDENT OF THE NEW YORK STATE COMMISSION IN LUNACY.

WE are glad to learn that, before accepting the presidency of the commission, Dr. Frederick Peterson took pains to ascertain that the duties of the office could be thoroughly performed without his devoting to them so much time as to interfere materially with the continuance of his regular professional work. It is seldom, if ever, wise for a physician to abandon his practice to take public office, even if the duties of the office are of a medical character.

A NEW SANITARY JOURNAL.

THE first number of a monthly journal called the *Public Health Record*, dated May, has reached us. It is described as the official organ of the Sanitary and Hygienic Society of New York. It is edited by Dr. M. B. Feeney and Dr. Herman Betz. The issue contains twenty-two full pages of reading matter and a fraction of another page, the pages of reading matter and those of advertisements being numbered continuously.

News Items.

Society Meetings for the Coming Week:

MONDAY, May 27th: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, May 28th: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, May 29th: Auburn, N. Y., City Medical Association; Berkshire, Massachusetts, District Medical Society (Pittsfield).

SATURDAY, June 1st: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Marine-Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera and plague were reported to the surgeon-general during the week ending May 17, 1901:

Smallpox—United States and Insular.

Prescott, Arkansas.....	May 8.....	5 cases.	
San Francisco, California.....	May 4-11.....	3 cases.	
Forty Counties in Colorado....	Apr. 1-30.....	430 cases.	
Chicago, Illinois.....	May 4-11.....	9 cases.	
Freeport, Illinois.....	May 4-11.....	2 cases.	
Clinton, Iowa.....	May 4-11.....	1 case.	
Lexington, Kentucky.....	May 4-11.....	8 cases.	
New Orleans, Louisiana.....	May 4-11.....	10 cases.	
Boston, Massachusetts.....	May 9.....	1 case.	
New Bedford, Massachusetts....	May 14.....	1 case.	
Detroit, Michigan.....	May 4-11.....	1 case.	
Grand Rapids, Michigan.....	Apr. 29-May 11.	6 cases.	
Omaha, Nebraska.....	May 4-11.....	18 cases.	
Manchester, New Hampshire....	May 4-11.....	8 cases.	
Camden, New Jersey.....	May 4-11.....	1 case.	
Newark, New Jersey.....	May 4-11.....	3 cases.	
New York, New York.....	May 4-11.....	107 cases.	19 deaths
Cincinnati, Ohio.....	May 3-10.....	8 cases.	
Cleveland, Ohio.....	May 4-11.....	32 cases.	
Dayton, Ohio.....	May 4-11.....	1 case.	
Philadelphia, Pennsylvania....	May 4-11.....	3 cases.	
Pittsburgh, Pennsylvania.....	May 4-11.....	7 cases.	
Memphis, Tennessee.....	May 4-11.....	27 cases.	2 deaths
Nashville, Tennessee.....	May 4-11.....	8 cases.	
Tacoma, Washington.....	Apr. 27-May 4..	2 cases.	
Huntington, West Virginia....	Apr. 13-May 11.	27 cases.	
Milwaukee, Wisconsin.....	May 4-11.....	1 case.	
Ponce, Porto Rico.....	Apr. 22-29.....	3 cases.	

Smallpox—Foreign.

Hong Kong, China.....	Mar. 23-Apr. 6..	22 cases.	17 deaths
Panama, Colombia.....	Apr. 29-May 6..	4 cases.	1 death
Paris, France.....	Apr. 22-27.....		20 deaths
Bremen, Germany.....	Apr. 13-20.....	1 case.	
Sheffield, England, Great Brit-			
ain.....	Apr. 13-20.....	1 case.	
Glasgow, Scotland, Great Brit-			
ain.....	Apr. 26-May 3..		3 deaths
Bombay, India.....	Apr. 8-16.....		6 deaths
Calcutta, India.....	Mar. 23-Apr. 13.		339 deaths
Karachi, India.....	Apr. 7-14.....	3 cases.	3 deaths
Madras, India.....	Mar. 30-Apr. 3..		3 deaths
Naples, Italy.....	Apr. 22-29.....	149 cases.	30 deaths
Mexico, Mexico.....	Apr. 28-May 5..	1 case.	
St. Petersburg, Russia.....	Apr. 13-20.....	13 cases.	1 death
Corunna, Spain.....	Apr. 1-30.....		2 deaths

Yellow Fever.

Havana, Cuba..... Apr. 28-May 4.. 1 case.

Cholera.

Bombay, India..... Apr. 8-16..... 3 deaths
Calcutta, India..... Mar. 23-Apr. 13. 194 deaths

Plague.

Lam Ko District, China..... Feb. 14-Mar. 26. 10,000 deaths
Bombay, India..... Apr. 8-16..... 681 deaths
Calcutta, India..... Mar. 23-30..... 2,557 deaths
Karachi, India..... Apr. 7-14..... 229 cases. 214 deaths
Nagasaki, Japan..... Apr. 19..... 1 case. 1 death.
(On Japanese steamship Taichu Maru.)

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending May 18, 1901:

DISEASES.	Week end'g May 11		Week end'g May 18	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	29	10	42	4
Scarlet Fever.....	679	49	702	59
Cerebro-spinal meningitis.	0	0	0	0
Measles.....	315	8	368	7
Diphtheria and croup.....	314	52	299	39
Small-pox.....	107	19	105	13
Tuberculosis.....	254	156	310	135

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending May 18, 1901:

BIDDLE, C., Surgeon. Detached from the Philadelphia Navy Yard and ordered to the *Indiana*.

DIEHL, O., Surgeon. Detached from the *Indiana* and ordered to the Philadelphia Navy Yard.

GROVE, W. B., Passed Assistant Surgeon. The order appointing him a member of the examining board at Annapolis is revoked.

WISE, J. C., Medical Director. Appointed a member of a board for the physical examination of candidates for appointment to the Naval Academy.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from May 11 to May 18, 1901:

BLOCK, WILLIAM H., Captain and Assistant Surgeon, United States Volunteers, is granted leave of absence.

CARLING, JOHN, Captain and Assistant Surgeon. The leave of absence granted him is extended one month.

CUTLIFFE, WILLIAM O., Captain and Assistant Surgeon, United States Volunteers, is granted leave of absence for one month.

MASON, CHARLES F., Captain and Assistant Surgeon, will proceed to Fort Sam Houston, Texas, to relieve CHARLES P. BYRNE, Lieutenant-Colonel and Deputy Surgeon-General, who will proceed to St. Paul for duty as chief surgeon of that department.

WILKINSON, H. BROKMAN, Captain and Assistant Surgeon, United States Volunteers, will, upon the expiration of the leave of absence granted him, proceed to San Francisco for transportation to Manila.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending May 16, 1901:

DUFFY, FRANCIS, Acting Assistant Surgeon. Granted leave of absence for two days from May 21st.

FOX, CARROLL, Assistant Surgeon. To proceed to Sitka and Juneau, Alaska, for special temporary duty.

GODFREY, JOHN, Surgeon. Upon being relieved by Surgeon J. J. KINYOUN, to proceed to Wilmington, North Carolina, and assume command of the service, relieving Surgeon T. B. PERRY.

GREENE, J. B., Passed Assistant Surgeon. Granted leave of absence for ten days from May 15th.

MASON, M. R., Hospital Steward. Relieved from duty at San Francisco and directed to proceed to Dutch Harbor, Alaska, and report to the medical officer in command for duty.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for one day.

PERRY, T. B., Surgeon. Upon being relieved from duty at Wilmington, North Carolina, to proceed to Baltimore and report to the medical officer in command for duty and assignment to quarters.

STIMPSON, W. G., Passed Assistant Surgeon. To proceed to Guthrie, Oklahoma, for special temporary duty.

THORNBURY, F. J., Assistant Surgeon. Relieved from duty at Chicago and directed to proceed to Dutch Harbor, Alaska, and assume command of the service.

ULRICH, C. F., Acting Assistant Surgeon. Granted leave of absence for twelve days from May 14th.

WASDIN, EUGENE, Surgeon. Bureau order of May 14th, directing Surgeon WASDIN to proceed to Gardner, Illinois, is revoked.

WOODWARD, R. M., Surgeon. Granted ten days' extension of leave of absence.

YOUNG, G. B., Passed Assistant Surgeon. Granted leave of absence for two months and twenty-two days from May 30th.

A Knighthood for Mr. Treves.—Mr. Frederick Treves, C. B., F. R. C. S., was knighted by King Edward on May 4th, in recognition of his services in South Africa.

A New York City Physician Knighted by the King of Italy.—Dr. Carlo Savini, of New York, has been made by the King of Italy a Knight of the Order of the Crown of Italy.

The Medical Club of Philadelphia gave a dinner on May 23d at Philadelphia, the guest of honor being Dr. Walter Wyman, surgeon-general of the United States Marine-Hospital Service.

The New York State Bureau of Bacteriology and Pathology.—Dr. George Blumer, of the Bender Laboratory at Albany, has been appointed director of the new Bureau of Bacteriology and Pathology, established by the State of New York.

A New Federal Quarantine Officer for San Francisco. We learn that Dr. D. A. Carmichael, the recently appointed Federal quarantine officer for San Francisco, has arrived in that city. Dr. Carmichael's success in suppressing the plague in Honolulu may account for his appointment.

A Physician Celebrates his Golden Wedding Anniversary.—Dr. and Mrs. John F. Heinz, of St. Joseph, Mo., celebrated their fiftieth wedding anniversary recently. They were married in Chicago in 1851. Dr. Heinz has been a practising physician for many years and is still active in the profession. In the early days he was a minister of the German Methodist Church.

Louisiana Citizens Object to a Lepers' Home.—The projected establishment of a lepers' home in the parish of Jefferson, on the river, some eighteen miles above New Orleans, La., has thrown the residents into a fever of excitement. The citizens of the parish have entered a protest with Governor Heard. If this fails they openly announce their intention to prevent the establishment of the institution by force of arms.

Changes of Address.—Dr. H. A. Bernstein, to No. 10 West One Hundred and Eighteenth Street, New York; Dr. Isaac M. Heller, to No. 2121 Bathgate Avenue, New York; Dr. Dwight W. Hunter, to the Bryant Studios, No. 80 West Fortieth Street, New York; Dr. Robert H. Pierson, to No. 505 South Warren Street, New York, N. Y.

Magnetic Healers are Fined in Missouri.—Professor Benjamin A. Weltmer and Joseph H. Kelly, who operated the "American School of Magnetic Healing" at Nevada, were fined \$1,500 each in the Federal Court on May 12th. The charge was one of using the United States mails for the purpose of fraud, by promising, for consideration, to cure persons of poverty and all known ailments through "absent treatment" and "mental suggestion."

Cuban Physicians Inspect Bellevue Hospital.—Two Cuban physicians and a Cuban commissioner appointed by the governor-general of Cuba to examine hospitals for the insane in the States of New York and Pennsylvania, visited Bellevue Hospital on May 19th. They were shown through the wards and inspected the insane pavilion under the guidance of Dr. Young.

Philadelphia has more Deaths than Births.—The report of the chief registrar to the Board of Health on May 7th was rather startling, in that it showed that during the preceding week and last year there were in Philadelphia more deaths than births. It has generally been thought that this condition applied only to the city of Paris. During the last week there were in this city 413 births and 565 deaths. During the last year there were 10,013 births and 10,510 deaths.

The Governor of Minnesota Reverses the Action of the State Medical Board.—Governor Van Sant, of Minnesota, has reversed the action of the State Board of Medical Examiners in the case against Dr. Edward N. Flint, who was charged by the board with unprofessional conduct, and action looking to the revocation of his license taken last January. The Governor's action is based upon an opinion from Attorney-General Douglas, who found that the complaint and evidence in the case were too widely at variance to render the charge effective.

The Chicago Eye, Ear, Nose, and Throat College is now established in its own building, No. 206 East Washington Street. The two lower floors are devoted to the dispensary, clinic, and college lecture rooms, while the upper three floors are devoted to hospital purposes. The operating rooms, one for nonpurulent and the other for purulent cases, and the sterilizing room are furnished in the most approved style and equipped with the most modern instruments and apparatus.

Delegates from the Georgia Medical Society Attend a Pharmaceutical Convention.—Among those who attended the meeting of the Georgia State Medical Society at Augusta was Dr. George F. Payne, representing the Georgia Pharmaceutical Society. Dr. Payne invited the society to send delegates to the pharmaceutical convention, which was to meet in Atlanta on May 21st. This invitation was cordially accepted and the convention appointed Dr. H. R. Slack, of LaGrange; Dr. Virgil Hardon, of Atlanta, and Dr. K. P. Moore, of Macon, delegates to meet with the pharmacists at their Atlanta convention.

Funeral of Dr. Charles Rice.—The funeral of Dr. Charles Rice took place on May 16th in the chapel of Bellevue Hospital. Men prominent in medicine and scientific pursuits and the representatives of many medical and scientific institutions were present. Henry St. George Young, the Bellevue chaplain, conducted the services. The honorary pallbearers were Professor Joseph P. Remington, of Philadelphia; Professor Henry Kraemer, of Philadelphia; Professor Henry H. Rusby, of the New York College of Pharmacy; Ewen McIntyre, first president of the New York College of Pharmacy; Thomas S. Brennan, Deputy Commissioner of the Department of Charities, and James Gerrity. Eulogies of Dr. Rice were made by Professor C. F. Chandler, Commissioner of Charities, John W. Keller and Professor J. P. Remington. The burial was at Woodlawn Cemetery.

The New York County Medical Association Honors its Counsel.—As a token of its appreciation of the legal work he has done for it within the last year, the New York County Medical Association presented to its counsel, Mr. James Taylor Lewis, at a recent meeting of the members held at the New York Academy of Medicine, a bronze figure designed by Paul Daudez, about thirty-seven inches high. The figure is that of a youthful warrior and is emblematic of "Duty." Dr. E. Eliot Harris made the presentation speech.

The Craig Colony for Epileptics.—The legislature of New York, just adjourned, passed a special appropriation bill giving the colony \$137,050. The chief item in the bill is one of \$90,000 for additional cottages for patients. There are now some twenty-eight cottages and buildings at the colony, which are occupied by seven hundred patients. The new appropriation will provide for eight or ten additional cottages and increase the epileptic population to a thousand. An appropriation of \$125,000 was also given the colony for maintenance, beginning October 1, 1901.

New Buildings for the Harvard Medical School.—A magnificent group of buildings for the Harvard medical and dental schools is to be erected in Boston at a total cost of over \$2,000,000. Five buildings will be devoted to the medical school and one to the dental school, and there will also be a power-house. All are to be classical in style and built on the unit system, which will admit of almost unlimited harmonious addition. The five buildings of the medical school will surround three sides of a court. All the buildings will have a light stone exterior and will be fireproof.

Gifts to the New York Academy of Medicine.—The New York Academy of Medicine has recently received a number of gifts. Dr. Abraham Jacobi presented to it on his fiftieth anniversary as a physician, a collection of old German text-books. It has just received from Dr. Charles L. Dana, one of its vice-presidents, a collection of framed photographs of the statues and temples at Epidaurus of Æsculapius, and the trustees of the institution have received a gift of \$10,000 from Mrs. Sarah Barker Gibbs and Miss George Barker Gibbs for the establishment of a fund to be known as the Edward N. Gibbs memorial prize fund. The income of this fund is to be awarded triennially to the American physician who shall present the best original essay on the ætiology, pathology and treatment of the diseases of the kidney.

Hindoo Physician Arrested for Practising without a Certificate.—Dr. Albert De Sarak, of No. 413 West Fifty-seventh Street, New York, was arraigned in court on May 7th by agents of the County Medical Society on a charge of practising medicine without a medical certificate. One agent testified that he had called at the office of the alleged physician and had been treated three times for imaginary ills. Dr. De Sarak says he is a Hindoo, an Oriental scientist, a general delegate to the Scientific Academy of Sauceteur, of Paris, and a member of the Oriental Society of Thibet and Calcutta. He admitted that he was not registered, but said that he was not practising as a physician and had made no pretense at practising medicine. Magistrate Meade held him in \$300 bail for trial.

The Cornell University Medical College Acquires a Valuable Library.—The Cornell University Medical

College has acquired the library of the late Dr. Felix Victor Birch Hirschfeld, professor of pathology and pathological anatomy at the University of Leipsic and director of the Leipsic Pathological Institute. This library, which contains about five thousand volumes, said to be one of the most valuable pathological libraries in existence. It is a collection of the periodical literature of Germany, France, and England on pathological subjects for more than fifty years, and contains detailed descriptions of the many discoveries made in that time. Many of the publications are no longer in existence, and copies of them are unobtainable. The purchase was made by Professor James Ewing in the name of the Loomis Laboratory. About \$10,000 was paid for the books.

New York City will Appeal from Barren Island Decision.—Although the Appellate Division of the Supreme Court has declared that the law passed by the legislature last year to prevent the rendering of garbage on Barren Island is unconstitutional, the fight in the courts to prevent the Sanitary Utilization Company from carrying on its business in the disposal of garbage is not ended. The case will be carried to the Court of Appeals. The action on which the Appellate Division gave its decision was brought by the Health Board to enforce the provisions of the law against the Sanitary Utilization Company. The decision says that the act of driving the Sanitary Utilization Company from Barren Island is neither just, fair, nor reasonably connected with any benefit to the community. Justice Patterson characterizes the act of the legislature as arbitrary, and is framed in the interest of the general public of New York City.

Consumptive Immigrants to be Excluded from the Ports.—Persons afflicted with consumption or tuberculosis of the lungs are among those whom the immigration commissioners have been directed to exclude from the United States. The following order was issued some time ago, directed to the Commissioner of Immigration at New York: "Sir—The bureau acknowledges the receipt of your letter of 1st instant, requesting that an opinion be procured and promulgated for the information of officials of this service as to whether tuberculosis of the lung can be classed as a contagious disease. Your said letter was referred to the supervising surgeon-general, Marine-Hospital Service, and was returned by him, under date of 3d instant, with the following indorsement: 'Respectfully returned to the commissioner general of immigration, Treasury Department, with a statement that tuberculosis of the lungs is now considered a contagious disease.' The officers under your jurisdiction should be informed as to this opinion, for their guidance in considering the admissibility of aliens, under Section 1 of the act approved March 3, 1891."

The New Medical Member of the State Commission in Lunacy.—Governor Odell has appointed Dr. Frederick Peterson, of New York, the medical member of the State Commission in Lunacy, in succession to Dr. Peter S. Wise. Dr. Peterson becomes by virtue of the appointment also president of the commission. Dr. Peterson's appointment is for six years, and he will receive a salary of \$5,000 a year and \$1,200 annually for expenses. Dr. Peterson was born in Minnesota in 1859 and graduated from the medical department of the University of Buffalo in 1879. Subsequently he studied for several years in Vienna, Strassburg, Leipsic, Stockholm, Paris, and

London. He practised medicine in Buffalo for several years, and then for three years was first assistant physician in the Hudson River State Hospital for the Insane, at Poughkeepsie. In January, 1888, he began practice in this city. He was professor of general pathology and director of the laboratory in the University of Buffalo from 1882 to 1884, and was pathologist to the State Hospital for the Insane and Erie County Insane Asylum at Buffalo. As a member of the State Charities Aid Association he took an active part in the establishment of the Craig Colony for Epileptics, at Sonyea, N. Y., and has been president of the board of managers of the colony from its establishment, in 1894. He was president of the New York Neurological Society from 1898 to 1901, and professor of insanity at the Women's Medical College until it was merged with Cornell University.

A Faith Curist Sent to Jail in Default of a Fine of Five Hundred Dollars.—A Faith Curist and Dowieite churchman of Valhalla, N. Y., who allowed his two-year-old adopted daughter to die of pneumonia without medical attention was sentenced on May 23d. The judge, in speaking of the prisoner, said: "The trouble with him is that he takes the ground that he is all right, and will do the same thing over again—he would do it to-morrow. He says he did this deliberately. He violates the laws because he wants to. It might be applied just as reasonably to murder or any other crime. Feeling as I do, I cannot suspend sentence. He has no defense, except that he does not wish to obey the law. He sets up his religious views against the laws of the State. I believe he is honest in his views, but they lead him into violation of the law. The child died from neglect, and the law requires that a man shall care for those depending upon him."

When asked what he had to say in his defense, the prisoner replied: "Nothing."

The judge then said: "The maximum punishment for the crime of which you are convicted is one year in prison or a fine of \$500, or both."

"I refuse to pay the fine," exclaimed the prisoner.

"You wait until I get through," said the judge, "before you say what you will or will not do. The jury recommended you to the mercy of the court. In view of this, the sentence of the court is that you pay a fine of \$500, and in failing to pay it you stand committed to the county jail at \$1 a day until it is so paid. You can pay it or be a martyr to your faith if you wish to."

The Clark County (Ky.) Medical Society, at its recent meeting, elected the following officers: Dr. H. C. Sharp, president; Dr. Cad Jones, vice-president; Dr. J. T. Davis, secretary and treasurer.

The Washington County (Pa.) Medical Society has elected these officers for the next year: President, Dr. W. R. Thompson; vice-president, Dr. G. A. Linn, of Monongahela; secretary, Dr. J. A. McKean, and treasurer, Dr. A. E. Thompson, all of Washington.

The Kansas Eclectic Medical Association has elected the following officers: Dr. E. G. Locke, of Holton, president; Dr. M. Averill, of Barkley, first vice-president; Dr. M. Michener, of Wichita, second vice-president; Dr. E. B. Packer, of Osage City, secretary; Dr. W. C. Hamilton, of Topeka, treasurer.

The Schuylkill County (Pa.) Medical Society has elected the following delegates to the Convention of the American Medical Association, in St. Paul, Minn., in

June: Dr. T. J. Birch, Dr. David Taggart, Dr. R. W. Montelius, Dr. G. H. and Dr. A. H. Halberstadt, Dr. G. W. Farquhar, Dr. J. C. Williams, and Dr. J. C. Biddle.

The Clinical Society of the District of Columbia will give its annual banquet in Washington, D. C., on Tuesday evening, May 28, 1901. An elaborate programme has been arranged by the committee, of which Dr. W. M. Barton is chairman, and Dr. Wells, Dr. James, Dr. Ramsburgh, and Dr. De Vries are the other members. The society then adjourns for the summer.

The Cayuga County (N. Y.) Medical Society.—The ninety-fifth annual meeting of the Cayuga County (N. Y.) Medical Society was held on May 8th. Officers were elected as follows: President, Dr. D. A. White, of Montezuma; vice-president, Dr. S. E. Austin, of Auburn; secretary, Dr. A. J. Forman, of Auburn; treasurer, Dr. A. W. Gilmore, of Auburn.

The Savannah Academy of Medicine.—A new medical society has effected permanent organization at Savannah, Ga., under the name of the Savannah Academy of Medicine, with the following officers: President, Dr. A. A. Morrison; vice-president, Dr. Frederick Wahl; secretary, Dr. J. Oliver Cook; treasurer, Dr. G. L. Harman. The society will meet twice a month, viz., on the first and third Mondays.

Texas State Medical Association.—At its recent meeting at Galveston, the following officers of the Texas State Medical Association were elected for the ensuing year: President, Dr. H. Taylor Hudson, of Belton; first vice-president, Dr. S. C. Root, of Houston; second vice-president, Dr. W. C. Nixon, of Gonzales; third vice-president, Dr. W. A. Watkins, of Kemp. El Paso was selected as the next meeting place, and April 4, 1902, was named as the date.

The Mississippi State Medical Association recently elected the following officers: President, Dr. J. M. Buchanan, of Meridian; vice-presidents, Dr. C. M. Mitchell, of Pontotoc, and Dr. Anthony Miller, of Pantherburn; secretaries, Dr. C. H. Trotter, of Winona; Dr. B. L. Culley, of Jackson, and Dr. D. S. Humphreys, of Greenwood; treasurer, Dr. J. F. Hunter, of Jackson; delegates to the American Medical Association, Dr. Barr, of Starkville, and Dr. Featherstone, of Macon.

The Kansas Medical Society.—At the recent meeting of the Kansas Medical Society at Pittsburg, Kans., the following officers were elected for the ensuing year: President, Dr. L. H. Munn, of Topeka; vice-president, Dr. Ryan, of Coffeyville; recording secretary, Dr. W. A. McVey, of Topeka; corresponding secretary, J. W. May, of Kansas City, Kans.; treasurer, Dr. W. E. Barker, of Chanute. The society also decided to conduct and publish a medical journal at Topeka.

The New York Medical Society for Clinical Research held its meeting on Monday evening, May 13th, at 311 East Broadway. The subjects for discussion were: The Regulation of Admission to Membership and The Lodge Question. The question of cooperative drug stores was also dwelt upon, but for lack of time this question was postponed to the next meeting, to be held on Monday, May 20th, when a paper will be read on Infantile Diarrhœa, by Dr. Heller and Dr. Lubman.

Meeting of the Society of Medical Jurisprudence.—The principal speaker at the meeting of the Society of Medical Jurisprudence of New York City, on May 13th, was William P. Mason, professor of chemistry at Rensselaer Polytechnic Institute. His address was on the subject of the danger lurking in the present method of harvesting ice and the necessity of having the ice industry placed under the supervision of the board of health.

The American Gastro-Enterological Association, at its recent meeting in Washington, elected the following officers: President, Dr. John C. Hemmeter; first vice-president, Dr. W. D. Booker, of Baltimore; second vice-president, Dr. S. J. Meltzer, of New York, and secretary and treasurer, Dr. Charles D. Aaron, of Detroit. The three members of the council are Dr. Max Einhorn, of New York; Dr. D. D. Stewart, of Philadelphia, and Dr. A. L. Benedict, of Buffalo.

The Medical Association of Howard County (Md.) met at Baltimore on April 23d. The following officers were elected: President, Dr. John U. B. Rogers, Ellicott City; vice-president, Dr. W. W. L. Cissel, Highland; secretary and treasurer, Dr. Wm. B. Gambrill, Alberton. Dr. F. Dyer Sanger, physician-in-chief to Child's Hospital and professor of clinical medicine, College of Physicians and Surgeons, Baltimore, read a paper on the Pharyngeal Tonsils, and Dr. John M. B. Rogers, of Ellicott City, one on Phosphaturia.

The Western Ophthalmologic and Oto-Laryngologic Association, at its sixth annual meeting, held in Cincinnati on April 11th and 12th, elected the following officers: President, Dr. C. R. Holmes, Cincinnati, O.; first vice-president, Dr. W. L. Dayton, Lincoln, Neb.; second vice-president, Dr. J. O. Stillson, Indianapolis, Ind.; third vice-president, Dr. H. W. Loeb, St. Louis, Mo.; treasurer, Dr. O. J. Stein, Chicago; secretary, Dr. William L. Ballenger, Chicago. The next meeting will be held in Chicago, April 10, 11, and 12, 1902.

The Fifth International Congress of Physiologists will be held this year at Turin, Italy, from September 17th to September 23d. In addition to the general secretaries for the work of preparation toward the fifth congress, Professor Frederic S. Lee (Columbia University, New York), secretary of the American Physiological Society, kindly consented to discharge secretarial duties in America. American physiologists who intend to be present are requested to notify him, in addition to communicating with Dr. Z. Treves, local secretary, Corso Raffaello, 30, Turin, Italy.

The Hunterdon County (N. J.) Medical Society has elected the following officers: President, Dr. G. W. Bartow, of Three Bridges; first vice-president, Dr. Howard Servis, of Junction; second vice-president, Dr. William H. Schenck, of Flemington; treasurer, Isaac S. Cramer, of Flemington; secretary, Dr. H. Sproul, of Flemington; reporter, Dr. G. N. Nest, of Rosemont; delegates to the American Medical Society, Dr. Leidy, Dr. Cramer, and Dr. Closson; delegates to the New Jersey Medical Society, Dr. Ewing, Dr. Closson, Dr. Johnson, and Dr. Romine.

The Association of American Physicians.—At the closing session of the sixteenth annual meeting of the Association of American Physicians at Washington the following officers were elected: President, Dr. James C.

Wilson, Philadelphia; vice-president, Dr. James Stewart, Montreal; recorder, Dr. S. Solis-Cohen, Philadelphia; secretary, Dr. Henry Hun, Philadelphia; treasurer, Dr. J. Crozier Griffiths, Philadelphia; councillors, Dr. Frank Billings, Chicago, and Dr. Francis P. Kinnicutt, New York; representative on executive committee of congress, Dr. William Osler, Baltimore; alternative representative, Dr. Francis H. Williams, Boston.

The Baltimore County (Md.) Medical Association, at its annual meeting, elected the following officers: President, Dr. J. F. H. Gorsuch; vice-president, Dr. R. Percy Smith; recording secretary, Dr. W. P. E. Wyse; treasurer, Dr. H. S. Jarrett; executive committee, Dr. H. B. Stevenson, Dr. J. E. Benson, Dr. Charles J. Hill; historical committee, Dr. Jackson Piper, Dr. H. L. Naylor, Dr. W. J. Todd; committee on medical jurisprudence, Dr. Charles G. Hill, Dr. P. F. Sappington, Judge N. Charles Burke; committee of honor, Dr. W. J. Todd, Dr. L. G. Smart, and Dr. B. F. Bussey.

The New York Academy of Medicine.—A stated meeting of the Academy was held on Thursday evening, May 16, 1901, at 8.30 o'clock. A memorial address on the late Dr. S. S. Purple, formerly president of the Academy, was presented by Dr. Stephen Smith, and papers were read on Sitophobia of Enteric Origin and on Syphilis of the Liver, by Dr. Max Einhorn; and On the Intestinal Intoxication Occurring in Mucous Colitis in Young Children, by Dr. Henry Koplík.

The New York Academy of Medicine.—At the meeting of the Section on Obstetrics and Gynecology, held on Thursday evening, May 23d, the following programme was presented: Presentation of patients. Exhibition of specimens, (a) Hydrosalpinx; (b) echinococcus-cyst of mesentery (?), by G. H. Ballery, M. D. Papers on Palliative Treatment of Fibroids, by H. C. Coe, M. D.; Fibroids Complicating Pregnancy, by Ch. Jewett, M. D.; Vaginal Hysterectomy for Fibroids, by J. Riddle Goffe, M. D.; Abdominal Hysterectomy for Fibroids, by Ch. N. Dixon Jones, M. D. General discussion by Dr. P. F. Munde, Dr. A. P. Dudley, Dr. J. Brettauer, Dr. H. N. Vineberg, Dr. E. J. Ill, Dr. LeRoy Broun, and others.

The Medical Society of City Hospital Alumni of St. Louis met on May 2d. The following papers were read: Report of a Case of Obstructive Prostatic Hypertrophy, with Remarks on the Bottini Operation, by Dr. Bransford Lewis; Observations on Migraine, by Dr. Frank R. Fry; and demonstration of specimens showing explanation of non-suppurative nasal headaches referable to the middle meatus of the nose, by Dr. Greenfield Sluder. At its meeting on May 16th the following papers were read: Surgical Operations on the Aged, with Report of Illustrative Cases, by Dr. A. H. Meisenbach; Vesico-vaginal Fistula (operation according to technique of Freund), Report of a Case, by Dr. F. L. Reder; The Use of the Double-knife in Histopathology, with Demonstration, by Dr. R. B. H. Gradwohl. Dr. Moore and Dr. Dorsett will contribute to the programme for June 6th.

The St. Paul Meeting of the American Medical Association.—We are informed that arrangements have been perfected with the Chicago & Northwestern Railway to run a special train from Chicago to St. Paul at 7.30 p. m. on Monday, June 3d, for the accommodation of such members of the American Medical Association and their friends as desire to attend the fifty-second an-

nual meeting. The train will be known as the "Medical Association Special," and will be composed of the latest pattern Pullman sleeping and buffet cars, and will run through to St. Paul without change. The fare will be \$13.50 for the round trip from Chicago, and tickets are good on the Medical Association special trains and also on all regular trains over the Chicago & Northwestern Railway, leaving Chicago May 27th, 28th, 30th, 31st, June 2d and 3d. Trains leave Chicago daily at 9 A. M., 6.30 P. M., 10 P. M., and 10.15 P. M. Sleeping-car rates on the Medical Association special and other trains will be \$2 for a double berth from Chicago to St. Paul. Each double berth provides sleeping accommodation for two persons. Those desiring special location may arrange for their reservation, either by letter or by personal application to Mr. Chas. Truax, of Truax, Greene & Co., 42-46 Wabash Avenue, Chicago, or at any office of the Chicago & Northwestern Railway (the city ticket office at Chicago is located at 212 Clark Street). On Monday, June 3d, a representative of the Chicago & Northwestern Railway will be at the office of Truax, Greene & Co. from 10 A. M. to 6 P. M.

A special trip to Yellowstone Park has been arranged for, including all charges, sleeping-car and dining-car service, hotel bills, stage-coach charges, etc., \$85 for each person. General arrangements for this train are in the hands of a special committee, consisting of C. A. L. Reed, M. D., Cincinnati, Ohio; Harold N. Moyer, M. D., 103 State Street, Chicago; F. C. Stanton, M. D., 34 Washington Street, Chicago; I. N. Love, M. D., 49 West Forty-fourth Street, New York city; John F. Fulton, M. D., St. Paul; and Charles Truax, 42 to 46 Wabash Avenue, Chicago.

The National Association for the Study of Epilepsy and the Care and Treatment of Epileptics held its first annual meeting in Washington, D. C., on May 14th and 15th. Papers were read on Condition of Epileptics in Russia, by Professor Paul Kovalevsky, of St. Petersburg; Condition of Epileptics in Belgium, by Professor Jules Morel, of Mons, Belgium; Care and Treatment of Epileptics in Switzerland, by Professor F. Kalle, director of the Swiss Institution for Epileptics, and Dr. T. Kalle, director of the private institution, Schloss-Pfullingau; Relating to Epileptics in Sweden, by Oskar Medin, M. D., professor at the Karolinska Institute, of Sweden; Relating to Epileptics in Turkey, by Dr. S. C. Zavittiano, president of the Imperial Society of Constantinople; Report on the Work at Bielefeld (Germany), by Pastor Siebold; Care and Treatment of Epileptics in Italy, by Professor C. Mangozzini, of Rome; Treatment of Epileptics in Brazil, by Dr. Horelburg, medical deputy of the consul-general in Rio de Janeiro; Condition of Epileptics in Brazil, by Dr. Secundino E. Sosa, specially appointed by the National Academy of Medicine of Mexico to furnish information to the association; Report on the Work of the National (British) Society for the Employment of Epileptics, by G. Penn Gaskell, Esq., secretary of the society, London, England; Epilepsy, by Frederick Peterson, M. D., president of the board of managers of the Craig Colony; An Ideal Colony for Epileptics and the Necessity for Broader Treatment of Epilepsy, by William P. Spratling, M. D., superintendent of the Craig Colony for Epileptics; Massachusetts State Hospital for Epileptics, by W. N. Bullard, M. D., president of the board of managers; Special Provision for Epileptics in Pennsylvania, by Wharton Sinkler, M. D., president of the board of managers of the Pennsylvania

Epileptic Hospital and Colony Farm; The Ohio State Hospital for Epileptics, by General R. Brinkerhoff, member of the Ohio State Board of Charities; The New Jersey Village for Epileptics, by H. M. Weeks, M. D., superintendent; Condition of Epileptics in Virginia, by William F. Drury, M. D., of Petersburg; Report on Condition of Epileptics in Connecticut, by Max Mailhouse, M. D., of New Haven; A Typical Case, by Mrs. S. A. Monroe, of Buffalo, N. Y.; State Provision for Epileptics in Texas, by B. M. Worsham, M. D.

The Physicians' Business Association, successor to the Physicians' Protective Association, at a recent meeting in Detroit, elected officers for the ensuing year as follows: President, Dr. G. L. Kiefer; vice-president, Dr. H. L. Obetz; secretary, Dr. W. J. Cree; treasurer, Dr. S. H. Knight.

Diphtheria.—A death from malignant diphtheria has been reported from Jersey City.—The schools of Dunellen, N. J., have been closed on account of the appearance of diphtheria there.—At Princeton, N. J., a distinguished patient is Esther Cleveland, daughter of Ex-President Cleveland. Her condition was at last accounts critical.

Small-pox.—As though the United States was not already supplied with an over-abundance of small-pox cases, recent incoming European steamships have brought more of the stricken to these shores. According to Dr. Alvah H. Doty, the Health Officer of the Port, most of the cases come from Naples, which is seriously infected. Dr. Doty has asked Surgeon-General Wyman, at Washington, D. C., to instruct his inspectors abroad concerning the existence of the disease at Naples, and to direct them to have lodging houses inspected and to look after vaccinations. A conference with the various steamship companies trading to Naples, at which he told them of the existing conditions, brought about their hearty co-operation. They have cabled to their agents, and have obtained promises to assist in enforcing the regulations. Fortunately, the time of passage from Naples to New York is about fourteen days, so that the incubation period is about covered.—The discovery of small-pox in a policeman resulted in the vaccination of the entire police force of New York city (about 1,200 men) last week.—Many places about New York, such as Long Island, Jersey City, Greenwich, Conn., and other points report sporadic cases.—Cities further west and east, where the epidemic has made its presence known, are Kansas City, Mo.; Chicago, Ill.; Grand Rapids, Mich.; Cleveland, Ohio, and Leominster, Mass., while reports from Alaska are that the scare there has not yet entirely abated.

The Pennsylvania Hospital Celebrates its One Hundred and Fiftieth Anniversary.—The one hundred and fiftieth anniversary of the founding of the Pennsylvania Hospital was celebrated at Philadelphia on May 11th. The commemorative exercises were opened by T. Wistar Brown, who read St. Luke's version of the parable of the Good Samaritan. Benjamin H. Shoemaker, president of the Board of Managers, extended a welcome to the "little provincial hospital" petitioned for by Franklin in 1751, and John B. Garrett, a member of the board, delivered the formal address. He entered exhaustively into the early history of the hospital.

The Annual Report of Roosevelt Hospital, New York city, for 1900 calls especial attention to the discrepancy between the resources of the hospital and its expenses. This condition of affairs, says the report, makes it necessary for the hospital either to decrease its work or increase its endowment. Last year 3,251 patients were under treatment, of whom 2,462 were treated without cost to the patients. In addition 7,614 cases were treated in the emergency department, but not detained for ward treatment, and there were 64,293 visits to the dispensary. The cost of maintaining the hospital and dispensary was \$155,296.76, which made a deficit for the year of about \$11,000. As the work of the hospital is growing every year the report says that an additional endowment of \$500,000 is needed.

Reception Hospitals for the Insane.—The overcrowding of the New York State hospitals for the insane having been relieved and the question of providing for the yearly increase of insane patients having been in a large measure solved, the State Charities Aid Association finds what it considers a complete solution of the problem in a plan which will at the same time relieve Bellevue Hospital of the necessity of receiving insane patients. After the new hospitals now being built have been completed there will remain to be found accommodations for six hundred patients in order to provide for the yearly increase for the next three years. It is proposed to build reception hospitals in this city and others of the larger cities of the State. In these would be gathered all cases of supposed insanity and recent cases of the committed insane to be examined and classified. Possibly curable cases would be kept for some time in the reception hospitals. The committee says that several of the best-known alienists and neurologists of New York will gladly serve as attending and consulting physicians if such a hospital were established at a convenient point. In speaking of the annual cost of maintaining the State hospitals the report says that it has been reduced from \$216.12 a patient to \$165.36 a patient.

Hospital Staff Changes.—Dr. S. Lewis Ziegler has been elected attending surgeon at the Wills Eye Hospital, Philadelphia. Dr. Ziegler is a graduate of the University of Pennsylvania, class of '85. He served as resident physician in the Germantown and Episcopal hospitals and was for two years house surgeon at the Wills Eye Hospital, where he was also assistant surgeon for seven years.—Dr. Harriet M. Balch, of Amityville, L. I., has been appointed physician at the Long Island State Hospital.—Dr. William D. Bacon, resident physician at the Baltimore (Md.) University Hospital, has resigned and been succeeded by Dr. Thomas H. Magness, of Baltimore. Dr. Edward C. Moriarty will leave the hospital shortly, and it is understood that his position will be filled by Dr. Joseph T. Devine, of New York city.—Dr. Luther H. Reichelderfer has been appointed superintendent of Garfield Hospital, Washington, D. C.

Hospital Buildings and Endowments.—Work will shortly be begun on a hospital at Montrose, Col. The estimated cost is about \$12,000.—Plans for an addition to the County Hospital at Milwaukee, Wis., have been accepted. The cost will reach \$80,000.—The will of the late Miss Anna Cohen, of San Francisco, bequeaths \$5,000 each to the Children's Hospital and the Mt. Zion Hospital of that city.—Plans have been completed for the \$50,000 sanitarium which is to be erected by a citizen of Fond du Lac, Wis., for the Sisters of St. Agnes, near that city.

The building will be ready for occupancy by November 1st.—Mrs. C. B. Newbold has given \$25,000 for the erection of an obstetrical amphitheatre for the maternity department of the University of Pennsylvania, as a memorial of her mother, the late Mrs. Thomas A. Scott.—The new maternity hospital building, the gift of J. Pierpont Morgan to the Society of the Lying-in Hospital of the City of New York, is nearing completion and will be ready for occupation early in the autumn. It occupies an entire block on Second Avenue, from Seventeenth to Eighteenth Street, and is eight stories high.—The work of converting the East Side Dispensary, at Nos. 322 and 324 East Third Street, New York, into the Austro-Hungarian Hospital, with thirty beds, free to members of all nationalities, was begun on May 1st. The sum of \$10,000 has been subscribed and another \$10,000 is pledged.—The will of N. C. Brockway, of New Haven, Conn., bequeaths \$2,000 to the Albany (N. Y.) City Homeopathic Hospital and Dispensary.—The Red Cross Medical Association of Detroit, Mich., has purchased what was formerly the Lafayette Hospital, in that city, and the building is now the Red Cross Hospital. An ambulance service will be installed.—The establishment of a Norwegian hospital in St. Paul, Minn., under consideration for the past two months, is a certainty, and by August 1st next the institution will be in operation. Property has been selected and will shortly be purchased.—The Women's Hospital Association of Batavia, N. Y., has received a check for \$500 from Mrs. Lawrence Williams, of New York.—J. Howard Wright, of New York, has given \$10,000 to the Muhlenberg Hospital of Plainfield, N. J., for an operating pavilion in connection with the new buildings of the hospital.—The will of the late Joel Goldenberg, of New York, bequeaths \$5,000 to the Mt. Sinai Training School for Nurses, \$4,000 to the Montefiore Home for Chronic Invalids, and \$3,000 to the Mt. Sinai Hospital. The entire residuary estate of the testator is bequeathed to Mt. Sinai Hospital for the purpose of creating and maintaining a ward in the hospital to be known as the Joel Goldenberg Ward. The diseases which are to be treated in this ward are to be determined by his nephew, Dr. Herrman Goldenberg, so soon as the arrangements for its establishment are completed. Should the estate be insufficient for the creation of a ward such as the officials of the institution deem proper, the funds are to be used for the maintenance of perpetual beds in the hospital.—The will of Leopold Feiss, of Cincinnati, Ohio, leaves \$500 to the Jewish Hospital, of that city.—By the will of Edward A. Hammond, of Long Branch, N. J., over which there is to be a contest, there is bequeathed \$5,000 to the Monmouth Memorial Hospital, at Long Branch.—A *crèche* for the children of women working in the factory, and a hospital for employees and sufferers in the immediate neighborhood, are to be provided by Crane Bros., manufacturers, of Chicago. The cost is estimated at \$50,000.

Births, Marriages, and Deaths.

Born.

FISKE.—In Richmond Hills, Long Island, on Wednesday, May 15th, to Dr. and Mrs. William Clarence Fiske, a daughter.

Married.

BLY—ORR.—In New York, on Tuesday, May 14th, Dr. Perry Amidon Bly, of Rochester, and Miss Julia Dodge Orr.

COCHRANE—RANDALL.—In Albany, on Thursday, May 9th, r. H. B. Cochrane and Miss Angelica Randall.

GORDON—TAYLOR.—In Abilene, Kansas, on Saturday, May 5th, Dr. R. N. Gordon, of Tacoma, Washington, and Miss Pearl aylor.

MERCHANT—SHEPHERD.—In San Miguel, Batopilas, Mexico, Tuesday, May 7th, Dr. Francis D. Merchant and Miss Grace npherd.

Died.

ESTABROOK.—In Denver, on Saturday, May 11th, Dr. Luther aniel Estabrook, in the sixty-ninth year of his age.

GAFFORD.—In Buena Vista, Colorado, on Friday, May 10th, r. John Lawrence Gafford.

HAYES.—In Plainfield, N. J., on Sunday, May 12th, Dr. imes Hayes.

MCDERMOTT.—In Avondale, Ohio, on Wednesday, May 8th, r. George Christie McDermott, in the fifty-third year of his age.

WEBB.—In Washington, on Tuesday, May 14th, Dr. Frank J. ebb.

Pith of Current Literature.

Boston Medical and Surgical Journal, May 16, 1901.

The Treatment of Psoas Abscess by Incision. By r. Robert W. Lovett.—The practical conclusions of this aper are: That fever is not necessarily an accompani-ent of psoas abscess formation; that where it does oc-ir, the prognosis is not so good as where it is absent; at the best method of operation is by a lumbar or an iliac incision, preferably the latter. It seems, on gen-eral principles, better to avoid recumbency for long peri-ods, which, of course, makes drainage by an iliac incision most impossible. It seems, therefore, best to put on a plaster jacket almost immediately after operation, to enable the patient to sit erect and to allow the abscess to drain almost from the first. In this way the author has obtained better results than by any other method.

Infantile Scorbutus. By Dr. John Lovett Morse.—The treatment in this constitutional disease consists of regulation of the diet and the administration of orange lemon juice. Either method alone is useful, but the combination is far preferable. The diet should be that suitable for the infant of the given age—breast milk, modified cow's milk, beef-juice. Modified milk should, unless contraindicated by complicating conditions, be given uncooked. The juice of half or the whole of a lemon or orange should be given daily. No drug is of the slightest use. During convalescence, iron may be indicated for the anæmia. Complicating gastro-enteric disturbance should be treated symptomatically, if neces-sary. The tenderness of the back and limbs demands that the infant be kept quiet. In the severer cases, re-cumbency on a Bradford frame or light splints to the affected limbs will afford much relief after the first few days; they are rarely needed for a longer time.

Neuritis Recurring after Atrophy of both Optic Nerves in a Case of Brain Tumor. By Dr. Edward R. Williams.—An interesting feature in this case is the discrepancy that exists between the great size of the tumor and the indefinite and mild clinical symptoms. A large part of the corpus callosum was totally destroyed, and the apex of the new growth appeared in the inter-tuncular space, where it compressed the second and third cranial nerves. The only effect on the third nerve was to irritate it sufficiently to cause a temporary dilata-tion of the left pupil. There was no paralysis of the ocular muscles.

A Case of Accidental Inoculation of Cancer in a Flesh Wound. By Dr. A. T. Cabot.—This case illus-trates the importance of taking great care, during the

removal of a cancerous growth, to go wide of the disease, so as to avoid the possibility of inoculation. It is also interesting to note that the antiseptics used to cleanse this wound did not suffice to prevent the survival and growth of the cancer elements.

Massachusetts General Hospital. Clinical Meeting of the Medical Board.

Medical Record, May 18, 1901.

The Recent Buffalo Investigations Regarding the Nature of Cancer. By Dr. Roswell Park.—As the result of study comes the conviction that cancer, in its inception, is purely local, and that the process of generali-zation is relatively slow, save in certain rare instances. Only by a combination of ante-mortem and post-mortem studies can its nature be solved. In the State laboratory the general lines of investigation include, not alone the histological and bacteriological methods, but the study of the subject also from a biological and a chemical stand-point. The studies already made seem to render it clear that death, in cases of cancer, comes about, as in so many other diseases, by a sort of terminal infection, which is a conspicuous feature of the disease, and has not hitherto attracted sufficient attention. It appears that the end is brought about by a distinct toxæmia, and particularly by a sort of hæmatogenous infection. It would appear that the so-called fatty degeneration of carcinoma cells is, at least in some part, due to the presence of organisms which have been mistaken for fat droplets or for epi-thelial cells in advanced fatty degeneration. The cancer juices, or so-called cancer milk, consist almost entirely of pure culture of these organisms. With regard to the yeasts and the fungi, which the Italians, in particular, believe to be the actual parasites of cancer, nothing has yet been established to prove that they may not in occasional in-stances produce cancer, but, so far as the Buffalo re-searches are concerned, the Italian observations have been neither absolutely disproved nor confirmed.

The author wishes to make it as evident as possible that carcinoma as a type of disease is, in every instance, an example of epithelial infection. Sarcoma, on the other hand, is an infection of connective tissue, probably by the same organisms, the tissue cells reacting some-what differently. As there are three distinct types of malarial parasite, so, we may suppose, do cancer orga-nisms manifest specific inclinations. As to the possibility of spontaneous retrocession, or disappearance of malig-nant growths, there is nothing in the protozoan theory of cancer which make this appear less possible or plausible than before, nor is there anything which shows it to be impossible.

Contracture of the Neck of the Bladder. By Dr. Charles H. Chetwood.—In treating the subject of con-tracture of the neck of the bladder, the author encroaches upon the more discussed subject of prostatic hyper-trophy, because these two maladies have much in com-mon, and also for the purpose of introducing a substitute for the Bottini galvanocautic operation. He notes that the most ardent advocates of the Bottini technique admit that some cases are not suitable to this mode of pro-cedure, and should be submitted to the more radical method of prostatectomy. Yet the distinction cannot be made before operating. Cystoscopy is of doubtful ex-pediency in advanced cases of prostatic hypertrophy, especially when there is evidence of pyelonephritis. This operation consists in adopting the perineal route as a means of approach to the neck of the bladder, and the galvanocautery knife as a means of removing the obstruc-

tion or the obtruding inflammatory or hypertrophied outgrowth.

Medical News, May 18, 1901.

On the Modern Treatment of Acute Gonorrhœa. By Dr. George Knowles Swinburne.—The author hesitates to lay down any one method of treatment as the ideal one assuring success. The truth is that the treatment of this disorder is as much an art to be cultivated as is the treatment of disease in any other department of medicine or surgery. Every case is a law unto itself. The diagnosis of an ordinary acute gonorrhœa is generally easy; in no case should the microscopic examination of the secretion be omitted, no matter how sure one may be of one's diagnosis. The gonococci arranged in fours, pairs, eights, etc., appear in groups within the pus cells, but they may also be seen outside and between the pus cells, and on or within the epithelial cells. They are best seen with an oil immersion lens, and an easy method of finding them is by means of the methylene blue stain. The knowledge that, after a negative diagnosis has been made, a patient may return in three or four days with an increased discharge containing a pure culture of gonococci, should prevent us from arriving at too hasty a conclusion. As to treatment, the use of permanganate of potassium solution, or perhaps a saline solution, is advised, to be used in irrigations several times a day, as hot as can be borne. The anterior urethra only is treated so long as the anterior urethra alone is affected. The germicide chosen should be used twice a day for three or four days and once a day for the rest of the first week; during the second week, every other day; during the third week twice, the fourth week once, and at the end of the fifth week. If there have been no discharge and no gonococci, the beer test is given—drinking beer every day for a week. If the patient stands this test he is discharged, but a final examination should be made only from four to six weeks later. This last examination, in the author's opinion, is specially important.

Chronic Gonorrhœa. By Dr. John Van Der Poel.—A hard and fast rule for the hygienic management of chronic gonorrhœa would be impossible to formulate. Each case must be judged upon its individual merits. As to the internal treatment: Alkalies in case of scalding, if reinfection is present; oleoresins when this has subsided; and later, antiseptics, as salol and urotropine. For the local treatment, the general rules are: (1) Care and conservatism in all procedures; (2) avoidance of overinstrumentation and injuries to the mucous membrane; (3) sufficient rest after passing through one system of treatment before beginning another in case the other is necessary; (4) regular and systematic use of the microscope in the control of the treatment—this is most essential; (5) surgical cleanliness and sterilization of all instruments.

On Gonorrhœal Conjunctivitis. By Dr. Ward A. Holden.—The author advocates the establishment of a public hospital in New York for the treatment of contagious diseases of the eye as being most desirable, not only for its humane features, but also as a purely economic measure.

Treatment of Gonorrhœal Stricture of the Urethra. By Dr. James R. Hayden.—As a broad, general rule, it may be safely stated that the best routine treatment for recent cases, and even fairly recent cases, of gonorrhœal stricture, is careful and gradual dilatation, combined with instillations or irrigations, and appropriate diet and internal medication to render the urine bland and non-irritating; if gradual dilatation fails, or for any reason

cannot be employed, we then resort to one of the cutting operations, being guided in our choice of procedure by the location and extent of the contraction, which is readily ascertained by the *bougie à boule*.

The Treatment of the Complications of Acute Gonorrhœal Posterior Urethritis. By Dr. James Pedersen.

Journal of the American Medical Association, May 18, 1901.

Amputation through the Hip Joint, with a Synopsis of Two Hundred and Sixty-seven Cases in which the Author's Method was Employed. By Dr. John A. Wyeth.—The author gives his method in detail and compares it with the methods of others. Of the two hundred and sixty-seven cases of disarticulation at the hip joint for all causes, fifty-three, or nineteen and eight-tenths per cent. of the patients died. Every fatal case is recorded, and the list includes a number that died from intercurrent disease, such as pneumonia and apoplexy although the cause of death was not justly referable to the operation. Several died from sepsis, one on the twenty-sixth day, from an avoidable cause of death. The author's method has met with almost universal approval, and the few objections which have been advanced as, for instance, the difficulty of disarticulation, and the free oozing from the large muscular surface divided, can no longer hold in the present improved technique of the operation. In suitable cases there is no longer any use for procrastination, and we are justified in urging operation in cases which up to now we have been content merely to recommend.

The Ocular Expression of Intranasal Lesions. By Dr. Robert Sattler.

A Brief Note on the Pathology, Diagnosis, and Treatment of Nasal Accessory-sinus Affections. By Dr. E. Larne Vansant.—The author draws attention to the excellent results obtained from forcibly syringing the openings and sinuses with hot dry air used under pressure.

The Reduction of Temperature in Fevers by Evaporation, Warm Water being Used for Baths. By Dr. Francis H. Williams.—In brief, the directions for giving evaporation baths are: Give a bath whenever the temperature rises to 102° F. Have the patient lie on a blanket during the bath, cover him with one thickness of surgeon's gauze, which, when moistened, will fit the skin perfectly, and sprinkle the skin with water at about 115° F. Be guided by the amount of water evaporated in giving the bath. So long as the temperature is high have as little clothing on the patient as possible. The author's statistics commend the procedure.

The Streptococcus Pyogenes in Gynecological Diseases. By Dr. G. Brown Miller.—The author calls attention to the characteristic signs by which the diagnosis of streptococcal pelvic infections that have extended beyond the uterus and have not caused a general peritonitis or systemic infection, can be made, and to the principles of operation.

Menière's Disease, with Report of a Case. By Dr. R. A. Bachmann.

The Financial Relations of the Medical Profession to the People and Public. By Dr. J. J. Conner.—The author believes that it is now time for the medical profession to form protective associations, and the one he is in favor of forming first is one for the weeding out of dead-beats, and the devising of ways and means for the better collection of our just debts.

A Study of the Ætiology and Pathology of Rheumatism, with Special Reference to "Rheumatic Diathesis." By Dr. A. P. Stoner.—According to the author, the difference between the gouty and the rheumatic subject is that one contains that special ingredient requisite to the propagation of the gouty poison, while that of the other harbors a rheumatic poison. He believes that both conditions are brought to the acute crisis by the agency of an infecting germ, the true biologic nature of which remains yet to be discovered.

A Case of Acute Dermatitis Caused by the Use of a Hair-dye having for its Base the Hydrochlorate of Paraphenylene Diamine. By Dr. A. D. Mewborn.

Difficulties and Dangers of Anæsthetics. By Dr. Daniel Eisendrath.

The Vesicular Murmur and its Relation to Pulmonary Health and Disease. By Dr. Thomas Neil McLean.

On the Relation between the Variety of Microorganisms and the Composition of Stone in Calculous Pyelonephritis. By Dr. Thomas R. Brown.

Complete Inguinal Extraperitoneal Hernia of the Bladder; Recovery. By Dr. J. F. Baldwin.

Philadelphia Medical Journal, May 18, 1901.

The Disinfection of Wounds with Pure Carbolic Acid. By Dr. Von Bruns.—The author does not hesitate to recommend the application of pure carbolic acid in small quantities and for one minute, followed by immediate irrigation with absolute alcohol, as a remedy that forms a valuable adjunct to our mechanical procedures in infected wounds. It would be a special providence if that remedy, which was the foundation of the whole antiseptic era, and which since then has again been generally discarded, were called upon to serve us anew in the battle against wound infection.

A Further Report on a Case of Presystolic Murmur Associated with Pregnancy. By Dr. James Tyson.

An Exceedingly Rare Case of Imperforate Anus. By Dr. Charles B. Kelsey.—The patient—a man, twenty-four years of age—fairly well nourished, though weighing only 107 pounds, was born with an imperforate anus. An opening was made in the perinæum during the first few days of life, but there has always been a free communication between the bladder and rectum by which urine has escaped *per rectum* and *feces per urethram*.

The Relations of the Public to the Medical Profession. By Dr. William H. Thomson.—The author regrets that one of the most creditable features of our profession in its acknowledgement of a code of professional ethics, which, as the term implies, relates to questions of honor in professional life and conduct, is interpreted by many as a purely trades-union code of the most despotic nature. The author wishes that some suitable plan of teaching anatomy and physiology in every high school, academy, and college could be devised. Legislation is relied upon to guard against the Christian Scientist.

Gastric Tetany, with Report of Cases. By Dr. William Gerry Morgan.

The Functional Tests of Hearing. By Dr. William Lincoln Ballenger.

Report of a Case of Rupture of the Eyeball from Contusion—Luxation of the Lens. Hernia of the Iris and Ciliary Body. By Dr. J. W. Sherer.

Anisometropia. By Dr. Norburne B. Jenkins.

Lancet, May 11, 1901.

The Pathology and Diseases of the Thyreoid Gland. By W. Edmunds, F. R. C. S.—In the first of the Erasmus Wilson lectures upon this subject, the author discusses the anatomy of the thyreoid and parathyreoid glands, and the effects produced upon dogs, monkeys, and other animals by their excision. In monkeys and dogs the symptoms commence generally about forty-eight hours after the operation. One of the first symptoms is a fibrillar twitching of the muscles, followed within a day or two by general convulsions. The respirations are hurried, and the temperature raised. These attacks last an hour or more and completely pass off, but the animal becomes apathetic, its hair falls out, and it has a difficulty in maintaining its equilibrium. Later the legs become rigid, ulcers appear on the skin, and the animal usually dies on about the fifth day. The prominence of the eyes is much affected; the palpebral fissures become narrower, and the eyes less prominent. The operation produces no effect whatever upon rabbits, which is due to the fact that two of the parathyreoid glands lie separate from the thyreoid, and consequently escape removal. The fatal termination in dogs cannot, as a rule, be prevented by thyreoid gland feeding.

The Importance of the Teaching of Insanity to the Medical Student and Practitioner in Relation to the Prevention of Insanity. By Dr. R. Jones.

Local versus General Anæsthesia in Certain Cases of Abdominal Surgery. By T. H. Morse, F. R. C. S.—The author has observed that when abdominal sections have been performed with local anæsthesia, little or no shock has followed. The causes of shock are twofold, viz., the anæsthetic, and the extent of injury to nerve structure produced by the operation. Shock varies in proportion to the skill of the administrator of the anæsthetic, and is often dependent upon the duration of the operation, and hence upon the amount of the anæsthetic which is inhaled. There are some patients whose condition of extreme exhaustion is such that the additional shock of general anæsthesia will just take away their only chance of life; in these cases the author recommends the use of local anæsthesia. He reports five cases in which freezing with ethyl chloride was used with great success to produce anæsthesia. No shock followed the operations, and, although all the cases were severe ones, three recoveries took place. It is extremely probable that pain is less acutely felt when the patient is *in extremis*.

The Ætiology and Treatment of Convergent Squint. By C. Worth, F. R. C. S.—In a case of squint there is, in addition to (1) the deformity, (2) a defective development of the fusion faculty, (3) nearly always a suppression of the vision of the deviating eye, (4) in the great majority of cases more or less amblyopia of the deviating eye, and (5) refractive error.

The deviation of a convergent squint consists in abnormality of the converging mechanism, whereby zero of convergence becomes some cross-eyed position instead of parallelism of the visual axes. It is especially important to remember that squint is not a muscular affection. The one essential cause of squint is a defective development of the fusion faculty. This is frequently associated with other developmental defects, such as abnormal shortness of the eyeball (hypermetropia) and congenital amblyopia. Hypermetropia, anisometropia, and congenital amblyopia, may any or all be present, but with a normal fusion faculty there will be no squint. The rational method of treatment is to endeavor to re-

move the cause of the squint by training the fusion faculty at an age when binocular vision should normally be developed. The author describes an instrument devised by himself for this purpose, which he calls an "amblyoscope," by means of which an amblyopic eye is trained to take its share in vision.

Operation is indicated when the periodic measurements of the angle of deviation show no decrease. The author has devised a special advancement operation which he describes in detail.

Diseases of the Maxillary Antrum, their Symptoms, Causes, and Treatment. By Dr. A. Brouner.—The commonest disease of the antrum is the so-called empyema, or purulent catarrh of the lining mucous membrane. In acute cases, which usually follow influenza or scarlet fever, the symptoms are well marked. Severe pain, neuralgic or throbbing, which increases on pressure or rapid movements of the head. The pain is generally intermittent and depends greatly on the amount of fluid in the antrum. The teeth are often painful, especially on pressure, thus leading to erroneous diagnoses. The cases mostly heal spontaneously without operative interference. Chronic empyema of the antrum is extremely common, but generally escapes diagnosis. The subjective symptoms are very slight. There is often recurrent infra-orbital neuralgia or a dull aching pain in the cheek, accompanied by swelling of the soft tissues. The only symptom complained of may be a bad smell in the nose. Distention of the cheek is not a sign of empyema of the antrum, but of cysts. These empyemata are usually of nasal, not dental, origin. The points in treatment to be aimed at are: (1) To open the antrum at the lowest possible point, so as to get good drainage of the cavity; and (2), to keep this opening patent until the disease has been cured. The author prefers opening the antrum through the alveolar process when possible. Under the use of eucaine it can be done with very little pain. The after-treatment is of great importance; it is usually stopped much too soon. Cysts of the antrum are not very common and are mostly of dental origin. Tumors of the antrum are frequently met with, the most common being carcinoma. The first symptoms are severe pain in the cheek and nasal discharge; nasal polypi are usually present and bleed freely on removal. If diagnosed early and the whole of the upper jaw removed, the prognosis is fairly good.

Mental Fatigue in School Children. By J. Bellei, M. D.—The author has studied the phenomena of mental fatigue in children, and has arrived at the following conclusions: (1) No conclusion could be drawn as to the influence of any single subject of teaching; (2) the first hour of lessons is a useful mental exercise because the children are able during that time to overcome the state of inattention in which they were at the time of coming to school; (3) the morning lessons do not produce great mental fatigue; (4) the midday rest is of great use to the children because it does not destroy the good effects of the mental exercise in the morning; and (5), though immediately after the midday rest the children are in the best condition of mind, an hour or so of application in the afternoon is sufficient to produce such a fatigue as to lead at the end of the afternoon lesson to the worst work of the day.

Three Cases of Myxœdema of Varied Type. By W. Wyllys, M. R. C. S.—The author reports three cases of myxœdema, all occurring in women past middle age. One case was quite acute, dementia developing rapidly, and passing into acute mania, and terminating in death

within a few months. The two other cases were markedly benefited by the thyreoid treatment.

British Medical Journal, May 11, 1901.

Pancreatitis. By A. W. Mayo Robson, F. R. C. S.—The essential and immediate cause of the various forms of pancreatitis is bacterial infection, this having been proved both clinically in the human subject and experimentally in animals. Though the infection may arise from the blood, as in pyæmia, or by direct extension from the neighboring tissues, as in ulcer of the stomach, yet the most usual channel is through the duct, as in the cases arising from gall-stones in the common duct, and from gastro-duodenal catarrh. Fat necrosis is commonly found in association with pancreatitis, but the fact that it is not found in all acute pancreatic diseases and that it has been noted during abdominal operations for other ailments, appears to show that the condition giving rise to it is not essentially a pancreatitis. As regards hæmorrhage in diseases of the pancreas, the author comes to the following conclusions: 1. That in certain diseases of the pancreas there is a *general* hæmorrhagic tendency which is much intensified by the presence of jaundice. 2. That hæmorrhage may apparently occur in the pancreas unassociated with inflammation or jaundice or a general hæmorrhagic tendency. 3. That both acute and chronic pancreatitis can and do frequently occur without hæmorrhage. 4. That some cases of pancreatitis are associated with local hæmorrhage. Inflammations of the pancreas may, therefore, be more conveniently and scientifically classified, like inflammation of other organs, as acute, subacute, and chronic; there is no reason to use the term hæmorrhagic pancreatitis except as a variety of acute pancreatitis. In acute infective pancreatitis treatment practically resolves itself into that of peritonitis commencing in the superior abdominal region. In the early stages the symptoms are usually so indefinite and the collapse so marked that no surgical procedure would generally be justified. The subacute form of pancreatitis is much more amenable to treatment as the indications are so much more definite and there is more time for careful consideration. By the time operation is performed an abscess has usually formed and is making its way toward the surface. Chronic pancreatitis must also be treated by abdominal section and drainage, but in this case the drainage is indirect and obtained by draining the gall-bladder by cholecystotomy, cholecystenterostomy, or duodeno-choledochotomy. The exact line of treatment cannot be determined until the abdomen is opened. The results of treatment of this class of cases have been most encouraging; of twenty-two cases operated on, only one died directly from operation. Of those recovering from operation, with the exception of two that died a few months later, complete recovery ensued.

Notes on a Mild Type of Small-pox (Variola Ambulans?) By Dr. F. Montizambert.—The author calls attention to the mildness in type of the small-pox that is at present epidemic in the United States and Canada. Between December 28, 1900, and March 29, 1901, 11,964 cases of small-pox were reported, with only 157 fatal cases; a mortality of 1.31 per cent. The extreme mildness of the disease, from time to time, defies all efforts to prevent its entrance into a community. There is, as a rule, but little initial fever, a very sparse, discrete eruption, and no secondary fever. In the country it is usually spoken of as chicken-pox or measles; in many lumber camps it goes by the name "cedar itch." Those affected by it go on with their work or business, and travel in public conveyances. Whether it is small-pox is doubted

by many, but it only attacks the unvaccinated or those not recently vaccinated; it attacks adults as often as children, and here and there a susceptible person develops a severe confluent or even fatal case. Vaccination is not compulsory in Canada; the author thinks it should be made so, as it furnishes the only means of stamping out the disease.

Note on the Probable Relationship of Vaccinia to the Inoculated Form of Small-pox in Man. By Dr. S. M. Copeman.—The author holds that it was not improbably from the inoculated form of small-pox, rather than from the ordinary variety, that much of the cow-pox, in the prevaccination era, was derived. The inoculation of small-pox is still carried out in Nubia; the author obtained some human small-pox material from that country, and found that while it could not be found to "take" directly on the calf, nevertheless results typical of ordinary vaccinia were obtained when the strain of lymph, after inoculation with it of a series of monkeys, was again transferred from the inoculation vesicles on this animal to the epidermis of the calf.

Note on a Case of Enormous Dilatation of the First Part of the Duodenum, Causing Great Dilatation and Proptosis of the Stomach; Gastro-jejunosomy; Necropsy. By G. Barling, M. B.

A Case of Gastro-jejunosomy for Complete Rupture of the Intestine at the Duodeno-jejunal Flexure. By B. G. A. Moynihan, F. R. C. S.—The case here reported was that of a boy aged six years, upon whom a gastro-jejunosomy was performed for complete rupture of the intestine at the duodeno-jejunal flexure following injury. A Murphy button was used and the patient did well for ten days, when he was seized with overwhelming abdominal pain and collapse, and died. At the autopsy a perforation of the duodenum was found, due to the button which lay in the ulcer that its pressure had produced. The case is especially interesting in that it shows that the passage of all the bile and all the pancreatic juice secreted into the stomach does not interfere in any degree with the functions of that viscus. The mere presence of aseptic bile alone in the stomach is insufficient to cause vomiting.

Case of Sarcoma of the Stomach. By Dr. A. C. Wilson.—The author reports a case of this comparatively rare affection, the tumor being situated on the greater curvature of the stomach, extending into the duodenum, and of the size of a small orange. The tumor was excised, a gastro-duodenostomy performed, and the patient made a perfect recovery, returning to work at the end of a month. Histological examination showed the growth to be a sarcoma of the mixed-cell type.

Perforating Gastric Ulcer; Operation Twenty-eight Hours after Perforation; Recovery. By H. W. Shettle, M. R. C. S.—The author reports the case of an anæmic girl, aged seventeen years, who suddenly showed all the symptoms of a perforating gastric ulcer, although no symptoms of ulcer had been previously present. Operation was not performed for twenty-eight hours after perforation, yet the patient made an uninterrupted recovery.

A Case of Tuberculous Disease of the Cæcum. By Dr. J. Maitland.—The author reports the case of a Hindu, aged forty-four years, who had suffered for eight years with attacks of pain in the region of the appendix. On examination, a cylindrical tumor was felt in the right umbilical region, firm in consistence, and fixed in one position. On opening the abdomen the tumor was found to be the tuberculous cæcum; eleven

and a half inches of gut were removed, lateral anastomosis performed by means of a Murphy button, and the patient made an uninterrupted recovery. Although the cæcum was extensively ulcerated, yet there had been no diarrhœa or hæmorrhage. There is reason to think that tuberculous disease of the cæcum is more common than is generally believed, and that some of these cases are mistaken for inflammatory disease of the appendix.

The Spontaneous Cure of Hydatid Cysts. By Dr. W. M. Stevens.—The author reports a case of apparent spontaneous cure of hydatid cysts, occurring in a man who had died of some other affection. The various explanations offered as to the cause of "spontaneous cure" are: 1. Natural death of the parasite. 2. Toxic action of the bile from its entrance into the cavity of the cyst. 3. Absorption of hydatid fluid. 4. Inordinate multiplication of the internal brood. 5. Changes in the ectocyst. The author reviews these various theories, and dismisses them all as unworthy of credence, with the exception of the last. The ectocyst, sometimes called the pseudocyst, is the external covering of the hydatid cyst and is derived from the tissues of the host. Changes take place in the ectocyst which result in an interference with the supply of pabulum to the parasite, leading to its death and to degenerative changes in the cyst and its contents. The changes which occur in the ectocyst are fibrotic in nature, and the changes in the cyst are comparable to those occurring in a tuberculous nodule undergoing caseation. Spontaneous cure is most likely to take place in organs in which fibrous overgrowths are common, *e. g.*, the liver. But the only rational treatment for cases of hydatid cyst is removal.

Experiments upon the New Specific Test for Blood. By Dr. G. H. F. Nuttall and Dr. E. M. Dinkelspiel.—The investigations of the authors confirm and extend the observations of others with regard to the formation of specific precipitins in the blood serum of animals treated with various serums. These precipitins are specific, although they may produce a slight reaction with the serums of allied animals. The substance in the serum which brings about the formation of a precipitin, as also the precipitin itself, is remarkably resistant. We have in this test the most delicate means hitherto discovered of detecting and distinguishing bloods, and one worthy of being put to forensic use.

Responsibility and Crime. By Dr. A. Robertson.

Centralblatt für Gynäkologie, April 20, 1901.

Atmocausis and Zestocausis.—Dr. Ludwig Pincus, in a critical review of the subject, regards Stöckel's innovation of lengthening the tube carrying the steam into the uterus as a great advantage. As a measure for the cure of uterine hæmorrhages, it is far superior to curetting, especially in cases in which the bleeding is dependent upon hæmorrhophilia. Atmocausis must always be attempted as a curative measure hereafter before extirpation of the uterus is performed, on account of uncomplicated uncontrollable bleeding occurring at the menopause. After abortion, it also stimulates uterine contractions in a manner in which no other agent works. When atmocausis is immediately employed in septic, puerperal endometritis, its effect is marvelous and far superior to that of the curette.

Zestocausis (hot air at a temperature of 239° F., introduced into the uterus for from two to four seconds) acts as a cauterizing agent and is valuable in treating cases of uncomplicated dysmenorrhœa by anæsthetizing the over-sensitive endometrium.

April 27, 1901.

Sterile Yeast in Gynecology.—Dr. Walter Albert writes that a method has been found of devitalizing yeast without affecting any of its well-known attributes. He has used ordinary brewer's yeast prepared in this way, by mixing one drachm of the yeast with one-half drachm of a twenty-per-cent. solution of sugar. This mass is carefully injected into the vagina and held in place with a tampon. It is permitted to remain for from six to eight hours. By this means he has reduced materially the virulence of the vaginal bacteria, has changed the severity of the vaginal secretion and has rapidly cured extensive erosions of the cervix. The author recommends the use of the yeast also as a preparatory step for vaginal operations.

Influence of Steam upon the Uterine Mucosa. By Dr. M. Koslenko.

Wiener klinische Rundschau, April 21, 1901.

Cysticercus Cerebri; Extirpation; Recovery.—Professor Maydl reports this case, giving in detail a most interesting recovery.

Reform of Hospital Service. By Dr. Paul Federn.

April 28, 1901.

Dental Cyst of the Superior Maxilla.—Dr. Josef Preindlsberger and Dr. R. Wodynski report such a case. The patient recovered after operation. The authors enter into the pathology and genesis of the condition.

A New Soap. By Dr. Heinrich Paschkis.

Centralblatt für innere Medizin, April 27, 1901.

Observations on Dialyzed Digitalis.—Dr. Schwarz-enbeck says that the only advantage he finds in this preparation of digitalis lies in the fact that it may be taken for a considerable period without producing gastric disturbance; but this is not absolutely uniform, and he urges that when the patient has received the benefits of the drug, it should be temporarily withdrawn.

Deutsche Medizin-Zeitung, April 25 and 29, 1901.

Cardiac Area as Influenced by External Causes. By Dr. Abée.

Treatment by Light.—Dr. E. Lindemann says that baths in artificial light stimulate the circulation, the metabolism, and the sweat secretion. The baths have a therapeutic value in anæmia, in chronic articular rheumatism, gout, and sciatica, and aid in obesity cures. The electric light, reflected upon the body in the strength of from fifteen to thirty ampères, provokes an active hyperæmia of the skin, which may become corrosive in its action. It has a decided bactericidal action that may be therapeutically employed for the cure of sluggish ulcers, acne pustules, furuncles, etc.

Münchener medicinische Wochenschrift, April 23, 1901.

Acute Intestinal Obstruction at the Junction of the Duodenum and Jejunum.—Professor Bäumler reports such a case. He enumerates the causes which may lead to the condition as follows: (1) Unusual length of the mesentery of the small intestine; (2) gastropnoxis; (3) enteropnoxis as influencing the position of the duodenum and the root of the mesentery; (4) the position of the duodeno-jejunal junction as related to the vertebral column; (5) pronounced lumbar lordosis; (6) extensive emaciation and weakness, as after a long and wasting illness; (7) chronic dilatation of the stomach in conse-

quence of pyloric stenosis; (8) prolonged dorsal position after operation; (9) too complete evacuation of the intestines before operation; (10) over-distention of the stomach by food or fluids; (11) chloroform narcosis; (12) operations on the biliary tract; (13) laparotomy, and (14), the application of a plaster-of-Paris corset. The last five may be classed as exciting causes, with the others as predisposing causes. Prophylaxis by avoiding the various elements above cited, so far as possible, is desirable.

Atropine Treatment of Ileus. By Dr. Bofinger.—A casuistic article.

Ileus Relieved by Atropine and Olive Oil. By Dr. Adam.

Deformity Following Fracture, and its Treatment. By Dr. Carl Beck.

Removal of the Fœtal Head Left in the Uterus. By Dr. L. Knapp.—A casuistic paper.

Manual Perforation and Extraction of the Fœtal Head. By Dr. H. Cramer.

Septicæmia and Amputation. By Dr. H. Dœrfler.

April 30, 1901.

The Action of Bactericidal Sera. By Dr. Max Neisser and Dr. Friedrich Wechsberg.

Blood, Cell-bodies, and Bacteria. By Dr. L. Heim.

Extracranial Syphilitic Disturbances of the Eyes.—Professor O. Schwarz describes gummata of the lids, tertiary papules, and syphilitic tarsitis, as well as luetic affections of the bones of the orbit and of the connective tissue of the eye. The cornea, the sclera, the iris and the ciliary bodies can also be affected. (*To be concluded.*)

Blood-poisoning and Amputation. By Dr. H. Dœrfler. (*Conclusion.*)

Prevention of Self-extubation. By Dr. E. Schlechtendahl.

Wiener klinische Wochenschrift, April 18, 1901.

Gastro-intestinal Symptoms of Renal Calculus.—Dr. Maximilian Sternberg says that, in addition to the other symptoms, certain gastro-intestinal phenomena are usually to be observed. These are mainly painful defæcation and the accumulation of flatus. This usually disappears with the renal colic and is best treated by the administration of opium. An increased arterial pressure usually accompanies the intestinal disturbance. Sometimes the gastro-intestinal symptoms are so prominent as to give verity to a form to be described as "alimentary renal colic." Diagnostically, it must be remembered that, in atypical cases of this kind, sensitiveness over McBurney's point may be present (being elicited by pressure upon the ureter), and changes in the urine may be absent.

Case of Otitic Abscess of the Brain Cured by Operation. By Dr. Otto Piffil.

Lyon médical, April 28, 1901.

Camphorate of Pyramidon in Phthisis.—M. B. Lyonnet and M. C. Lancon have used this drug in fifteen patients suffering from tuberculosis. They gave fifteen grains daily, which was administered in solution. There was diminished temperature in all cases, as well as a diminution of the night sweats. They believe it to be a valuable remedy.

Formation and Evolution of Obesity, Normal and Pathological. By M. Dufourt.

May 5, 1901.

The Sugars of the Blood. By M. Lepine and M. Boulud.

So-called Traumatic Serofibrinous Pleurisy.—M. F. Barjou and M. C. Lesieur doubt the rôle of trauma in direct production of a pleurisy, although their studies show that, when a latent infection is present, injury may call forth a serofibrinous pleurisy sooner than it might otherwise have developed.

Gazette hebdomadaire de médecine et de chirurgie, April 28, 1901.

Lateral Strangulation of the Intestine in an Umbilical Hernia.—M. Savoriaud reports a case of this character in which the patient developed gangrene of a portion of the small intestine in a strangulated umbilical hernia, which followed the removal of an ovarian cyst. Recovery followed the operation, which was complicated by the presence of a pelvic abscess.

Presse médicale, April 24 and May 1, 1901.

Intra-arachnoid Anæsthesia.—M. Tuffier defends the injection of cocaine by the intra-arachnoid method for the purpose of anæsthesia. He says the injection must be made slowly, should be done in the operating-room, and the technic must be closely followed. He is not discomfited by the one death in 2,500 following the use of cocaine in the spinal canal, saying that it is a low percentage of mortality, and the cases of death reported have occurred in those who were previously diseased, and the technics of the operation are not given in any case.

The Non-specificity of Grippe. By M. G. Rosenthal.
Treatment of Paralytic Luxation of the Shoulder. By M. Bothezat.

Journal des praticiens, April 20, 1901.

Cardiac Asthma. By M. Marklen.—A clinical lecture.

Enteroptosis.—M. Glénard says that women are more subject to the condition than men, the corset being a contributing cause, as well as the puerperium. Laparotomy, hepatitis, and nervous conditions also aid the development of enteroptosis. Among the determining causes are those of a *traumatic* nature (falls, pregnancy, and its sequels) and those of *hepatic* origin, typhoid fever, dysentery, alcoholic excesses, paludism. Toxic influences or nervous or emotional shocks may also aid in bringing about the condition. The treatment must include the elevation of the viscera, the increase of abdominal tension, the regulation of the stools, the stimulation of the secretions of the alimentary tract and their accessories, the regulation of the diet, and tonic treatment of the entire organism. Insomnia, nervousness, pain, and weakness must also be relieved. An abdominal binder, daily laxatives, the administration of alkalies and the daily regimen are the four great bases of treatment. Hydrotherapy, massage, and electricity may also be called into therapeutic use. The diet allowed is liberal and embraces the wasted meats, milk, wines, fish, fresh vegetables, cheese, fruit, chocolate, beer, cider, and the cereals.

Progrès médical, April 20, 1901.

Comatose Pernicious Fever.—M. Jean P. Cardamatis says that this is the most frequent and most dangerous of the forms of paludism as seen in Greece. It most often appears in June or July, becomes more rare during late autumn, and practically disappears in winter. The predisposing causes are malarial infection supervening upon an organism previously debilitated by anemia, the toxæmias, physiological abuses, intellectual and physical

fatigue, insolation, alcoholism, the puerperium, etc. Two forms are distinguished, the mild and the severe. The former is an exaggeration of the ordinary intermittent fever; the latter is accompanied by complete abolition of consciousness, of intellectual and physical function, and threatens the patient's life. In the pernicious form, tremendous rises of temperature are seen. If the temperature rises above 106° F., however, and a microscopic examination of the blood is not available, insolation must be given the preference in diagnosis. The mortality in favorable cases is about twenty per cent.; in unfavorable cases, about fifty per cent.

Riforma medica, April 3, 4, 5, and 6, 1901.

Four Cases of Congenital Cystic Lymphangioma. By Dr. E. Ligorio.—The cases reported were as follows: 1. A child, aged fourteen months, with a tumor on the right side of the chest in front, about the size of an orange. The presence of this growth was noted at birth, but it grew in size until it reached its present volume. It was independent of the mammary gland, and on palpation it seemed to be lobulated. The tumor was removed and proved to be a cystic lymphangioma. 2. A child, aged eleven months, with a tumor of the size of a walnut, situated in the scapular region, and covered with healthy-looking skin. The further history was the same as in the first case. 3. A girl, aged six years, with a lymphangioma of the size of an orange on the arm and forearm. The tumor proved to be a lymphangioma of mixed cystic and cavernous types. 4. A boy, four months old, with a tumor of the size of a hen's egg on the side of his neck at birth. The clinical characteristics of this growth pointed to a cystic tumor of some sort, and on removal a lymphangioma was found.

April 8, 1901.

Nitroglycerin in the Treatment of Epilepsy. By Dr. Romano Pellegrini.—The preparation usually known as nitroglycerin is not a well-defined compound, but an ether composed of glycerin, glycerin nitrate, and glycerin trinitrate. Field used nitroglycerin in epilepsy, and the author gives the results of a series of experiments with this drug in the treatment of epileptics. He found that a one-per-cent. solution of nitroglycerin in alcohol is always efficient as a sedative in epilepsy, preventing the recurrence of the attacks. In fifteen patients he found that during the three months in which nitroglycerin had been used there were fewer attacks than during the preceding three months in the same group of individuals. In ten cases out of fifteen the effect of nitroglycerin was better than that of bromides, for in these patients there were fewer attacks during the three months in which nitroglycerin was used than during the three months in which bromides were employed in the same persons. In seven cases, after the use of nitroglycerin, there was, in addition to this diminution in the number of attacks, also a diminution in the extent of the excitement which used to precede, accompany, or follow the attacks. Contrary to the observations of Koronocki and Andrews, no untoward effects were noted during the three months in which the treatment was tried. The author recommends an alternate use of nitroglycerin and of bromides in order to avoid the protracted use of either drug.

April 9, 1901.

An Elastic Bandage Allowed to Remain Tied Around an Arm for Twenty-seven Hours. By Dr. Oswaldo Cabibbe.—The patient was a man fifty-seven years old,

who had accidentally cut himself on the radial side of the left forearm near the styloid process. The hæmorrhage was very severe, and an elastic bandage was applied to the junction of the middle and lower thirds of the arm. After the arm had remained in this condition for twenty-seven hours, the patient was brought to the clinic. The lower part of the extremity was cold, blue, insensible, and immovable. The wound was treated, the arteries tied, and the ligature on the arm removed. Subsequently, it was found that the patient was suffering from arteriosclerosis and that a phlegmonous process had developed in the constricted extremity. The absence of sensation and the paresis remained for a long time, and the patient was discharged from the clinic without having been completely cured of these nervous disturbances. This case is without an equal on record, as the longest period during which an elastic bandage was known to have been left on an extremity was twelve hours in a case reported by Esmarch.

April 10, 1901.

On the Variations in Weight in Persons Confined in Prisons. By Dr. Giuseppe Cao.—The author has found that the majority, *i. e.*, seventy-five per cent., of prisoners confined in cells lose in weight during the first part of their term of imprisonment. Of these, about twenty per cent. lose a considerable amount of body-weight, say from five to ten kilogrammes (about ten to twenty pounds). Another group of prisoners, about fifty-five per cent., lose from about two to five kilogrammes (four to ten pounds). The remainder lose one or two kilogrammes only, or gain in weight. The gravity of the offense and the possibility of an acquittal or of a pardon have a great deal to do with the loss in weight of prisoners. Prisoners confined in rooms instead of cells increase in weight so soon as they are transferred from the cell to a better apartment.

April 12, 13, 15, and 16, 1901.

On Delusions of Jealousy (Jealous Insanity). By Dr. Romano Pellegrini.—The author treats of a form of insanity which is characterized by delusions of jealousy and persecution. There are also hallucinations of various kinds, particularly such as relate to the supposed infidelity of wife or husband. He reports five interesting cases of this kind which he has had under observation. The patients became very jealous of their wives, imagined that they were being deceived, and took all sorts of precautions and resorted to all kinds of expedients in order to detect the unfaithful one in *flagrante delicto*. In addition to this they, as a rule, abused their wives, constantly questioned them, and maltreated them, so that confinement in an asylum was necessary. In the first case, the patient, a man aged fifty years, whose wife was said to be a model of virtue, was cured of his delusions by a two months' sojourn at the asylum, where he was employed in gardening. The second patient remained in the asylum for two years and then went to America, where he lived for a few years, whereupon he returned to Italy and lived peacefully with his wife. He was a teacher of elementary schools, aged forty-eight years. In these two cases the jealousy was limited to questions of marital fidelity, and both patients were physical and psychical degenerates. Both were "excessively religious." In the three other cases the delusions and hallucinations were so violent that there was a strong tendency to homicide. The three patients killed their wives in accessions of jealousy. All three had been hard-working men of peaceful disposition before the onset of the delusions.

Vratch, March 21, 1901.

The Balantidium Coli as a Cause of Severe Diarrhœas. By Dr. N. S. Solovieff.—The author has observed a case of severe diarrhœa in which the balantidium was present in the discharges. Since 1857, when Malmsten first found the balantidium in the fœces of a patient with diarrhœa, until 1900, there have been seventy cases of this kind recorded in literature. The present case is the first of its kind to be reported in Siberia. The patient, a man aged fifty-four years, was admitted complaining of bloody stools, pain in the abdomen, anorexia, weakness, thirst, and chills. He was severely emaciated and anæmic, with a swollen abdomen and a desire to evacuate the bowels every twenty or thirty minutes. The discharges were mixed with blood, and contained *Balantidium coli* in abundance. Preparations of tannin, etc., were tried in vain; the patient became rapidly weaker and died on the third day after admission, this being the thirteenth day of the disease. The autopsy showed ulcerative colitis caused by the balantidium; fibrinous inflammation of the serous covering of the liver and spleen; emphysema of the lungs; œdema of the pia, and thickening of the aorta and cerebral vessels. The walls of the large intestine were thickened, congested, and œdematous, without connective tissue growth, and the mucosa was studded irregularly with round or ovoid ulcers up to a centimetre in diameter. The edges of these ulcers were red, slightly undermined and thickened in places. (*To be continued.*)

The Action of the Alkaloid Johimbin in the Animal Organism, and its Significance in the Treatment of Impotence. By Dr. N. P. Krykoff.—(*Concluded.*)—Experiments on dogs show that the alkaloid causes a fall of blood pressure almost immediately after injection, but the pressure rises again in a short time. The pulse rate is almost doubled. This fall of pressure depends upon a paralysis of the vasomotor centre, and the rise in the pulse rate is a compensatory phenomenon to the fall of pressure and is not dependent on any action of johimbin on the vagus. Large doses cause irregularity of the heart's action and finally paralysis of the heart, due to a gradual paralysis of the cardiac motor centres. The erection of the genital organ as a result of the administration of johimbin is therefore due to the fall of blood pressure, and the drug cannot be classed as an aphrodisiac in the usual sense, because the sexual centre and the sensory nerves of the penis have nothing to do with the erection. The author found, moreover, that the erection and swelling of the penis as a result of the administration of johimbin coincided with symptoms of general intoxication with this alkaloid, and therefore only came on when the system was already poisoned. The physiological data thus obtained do not indicate that the drug can be useful as a therapeutic agent in impotence. The author tried the drug on six physicians who offered to serve as subjects of experiment. Some of these men were relatively impotent as neurasthenics; the rest were healthy. They each took 0.005 grammes of johimbin three times daily for two or three days. In three cases this dose was followed by vertigo, headache, nausea, sweating, a feeling of heat, congestion of the conjunctivæ, and general malaise, without a trace of the specific action of the drug. In the other three patients there was no effect on the sexual function, but there was a feeling of general lassitude, inability to concentrate thoughts, and irritability of temper. The author concludes that neither is johimbin a harmless drug, nor can it be called an aphrodisiac.

A Case of Intussusception. By Dr. A. P. Krymoff.

Fibromyoma and Pregnancy. By Dr. I. S. Kalabine.

Excision of the Conjunctival Fornix. By Dr. A. A. Kahn.—An account of the value of this operation in trachoma. The author strongly advocates this radical measure in cases of chronic granular ophthalmia.

A Few Words Concerning the Heredity of Consumption. By E. E. Miller.

Roussky Archiv Patologyi, Klinitcheskoj Meditsiny i Bakteriologyi, January, 1901 (Russian Archives of Pathology, Clinical Medicine and Bacteriology.).

Absorption of Minute Quantities of Carbon Monoxide by the Blood, and a New Method of Determining the Presence of this Gas in the Air. By Dr. S. I. Kostine.—The fact that the blood has the property of absorbing carbon monoxide from the air has been known since the time of Claude Bernard. It has also been shown that minute quantities of this gas may be absorbed daily by the organism and may cause a chronic carbon-monoxide poisoning in the course of time. The methods of determining the presence of carbon monoxide in the air are very complicated and in most instances of poisoning by this gas only the cruder tests have been used. The author has found that the presence of oxygen hinders the absorption of carbon monoxide by the blood, and that the spectroscopic test is not so useful as it might be because the presence of reduced hæmoglobin masks the carbon-monoxide hæmoglobin by obscuring its absorption line. He has devised a new method of analysis for air containing carbon monoxide. The results of his investigations lead him to conclude as follows: It is impossible to determine the presence of carbon monoxide in quantities smaller than one part in ten thousand, unless one removes all the oxygen first. The absorption of carbon monoxide becomes greater as the quantity of oxygen in the air is diminished. Complete removal of the oxygen is effected most conveniently by means of an apparatus devised by the author. When the oxygen has been removed from the air it is possible to determine the presence of one part of carbon monoxide in forty thousand parts of air by shaking blood with air deprived of oxygen and then testing the mixture. Cooling the blood assists the absorption of carbon monoxide.

Miliary Tuberculosis of the Mammary Gland. By Dr. N. N. Michailoff.—The author reports a case in which he removed the mammary gland for tuberculosis. The patient was a woman aged thirty-three years. On examination the gland was found to be the seat of miliary tuberculosis. This condition was primary, as there were no other tuberculous lesions in the patient's body. The infection probably took place during lactation through the lactiferous ducts.

The Decomposition of Potassium Iodide in the Digestive Tract. By Dr. A. Stepnoff.—The author discusses the question as to the cause of the decomposition of potassium iodide in the gastro-enteric tract. The decomposition of the salts usually takes place only in the presence of oxygen derived from a substance which is easily reducible. Most pharmacologists do not admit that potassium iodide is decomposed in the stomach. On the other hand, some observers state that hydriodic acid is probably present in the stomach after the administration of potassium iodide, but that this compound is so unstable that it is impossible to separate it from the stomach contents. Kueltz fed dogs with potassium iodide and potassium bromide, and tested the stomach

contents for hydriodic and hydrobromic acids. He found that the quantity of hydrobromic acid exceeded that of hydriodic acid in these dogs. There is no doubt that potassium iodide is decomposed in the stomach, however, and this fact is still more evident from the gastric disturbances that often follow the use of the iodides. The causes of this decomposition are probably the nitrates of the saliva and the free acids of the gastric juice. The iodine thus liberated is immediately taken up by the albuminous compounds, even by the mucosa itself, and then by the alkaline salts of the blood. It is also probable that the iodides are decomposed in the duodenum, as the pancreas contains nitrites. The diarrhoeas which have been observed after the use of iodides also speak in favor of decomposition of these salts in the small intestine.

The Bacteriolysis of the Anthrax Bacillus. By Dr. J. Malfitano.—It may be stated with certainty that protoplasm has the property of forming ferments which eventually may destroy the very cell in which they have been formed. The author studies the question as to the possibility of such ferment-formation in the bacillus of anthrax. This self-digestion on the part of bacteria has been called bacteriolysis and the ferments causing the process are styled proteases. The author has found that if a pure culture of the anthrax bacillus on agar is emulsified with sterilized distilled water and kept at about 30° C. for a few hours, the bacteria will lose their shape and gradually become masses of detritus. He has also performed a series of experiments with antiseptics, as regards their influence upon bacteriasis, and has found that while some of these substances destroy protoplasm, they also hinder the activity of the ferment. Others change the reaction of the nutrient medium and thereby inhibit the action of the protease. The best results were obtained with chloroform, xylol, and thymol.

On Hyperkeratosis Diffusa Congenita. By Dr. M. Sniesareff.—The author reports a case of this rare congenital dermatosis. Congenital keratosis, or ichthyosis, is comparatively little known as yet, in spite of the fact that the first case was reported by Richter in 1792. and that, since then, over thirty cases have been recorded.

Chirurgia, February, 1901.

Gunshot Wounds Caused by Shells and by Ordinary Lead Bullets. (Notes of the Recent Campaign in Manchuria.) By Dr. V. A. Svenitzky.—The author gives an account of his experiences with gunshot wounds in the recent military operations of Russia against the Boxers in Manchuria. The weapons of the Chinese soldiers consisted of the greatest possible variety of firearms, beginning with a buckshot rifle and ending with a gun of the Mauser or Mannlicher type, and including all sorts of old types, Winchesters, etc. These old guns were used with the old-fashioned leaden bullets. The same may be said as to the Chinese artillery, with its wooden guns bound in metal, and its Sané and Hotchkiss types of modern construction. The Chinese shoot rapidly and a great deal at a time, but entirely aimlessly, says the author. They also use explosive bullets, as the author had seen several cases where bullets exploded in the tissues, but he was unable to secure samples of such bullets. They do not regard the Red Cross as a badge of non-combatants. The Russians use a triple-barreled rifle with nickel-plated shells. The author saw 115 cases of gunshot wounds in this campaign, one third of which were wounds with Mauser or Mannlicher rifles. The leaden bullets cause broad, gaping wounds, the shells

narrow, penetrating wounds. The modern bullets cause very little crushing, while the old ones often tear and crush the tissues, so that healing does not take place so quickly as with the modern shells.

Mesenteric Growths. By Dr. N. Trinkler.—A case of reticular sarcoma of the mesentery in a man aged thirty years. Removal was successful.

On Acute Intestinal Obstruction. By Dr. I. A. Bondareff.—The author reports five cases of acute intestinal obstruction, including one of volvulus of the sigmoid flexure, two of incarceration of the ileum, one of carcinoma of the ileum, and one of compression of the ileum. Four of these patients recovered after operation. The author attributes this good result to the facts that most of these patients applied, early in the disease, for relief, and that the obstruction was localized before the laparotomy.

Lamium Album in Uterine Hæmorrhages. By Dr. I. S. Kalabine.—The author has conducted some experiments with a view to determining the physiological action of *Lamium album* in uterine hæmorrhages, a remedy which he has used for fourteen years with success. He injected an infusion of *Lamium album* (1:10, 25 to 50 cubic centimetres) into the femoral veins of dogs, and registered the results of the injections on a kymograph by means of a uterine oncometer devised by Lindeman, which he attached to the uterus of the dog. He found that the drug produced contractions of the uterus which lasted for a considerable time. The blood-pressure was raised within a few minutes after the injection. The author uses the tincture of *Lamium album* in doses of forty drops in half a wineglassful of water every two hours, until the menorrhagia or metrorrhagia ceases. Good results were obtained in interstitial fibroids, in hæmorrhages due to inflammatory conditions of the adnexa, in postpartum hæmorrhages, incipient abortion, etc.

Inguinal Hernias. By Dr. Aleksei Martynoff.

The Radical Treatment of Inguinal Hernia. By Dr. N. A. Zviagintzeff.

American Journal of the Medical Sciences, January, 1901.

A Case of Multiple Fibromata of the Nerves, with Arthritis Deformans. By Dr. Robert B. Preble and Dr. Ludwig Hektoen.

The Relation of Cholelithiasis to Disease of the Pancreas and to Fat Necrosis. By Dr. Eugene L. Opie.

A Report of a Case of Typhoid Pleurisy. By Dr. Herman Camp Gordinier and Dr. August Jerome Lartigau.—Pleurisy is not a common complication of typhoid fever; when present it is ordinarily secondary to pneumonia, to an infarction, or to gangrene. Primary pleurisy is regarded as very rare. Bacteriological study usually shows the presence of the more common members of the pyogenic group of micro-organisms. However, a few isolated reports in literature demonstrate the ætiological relationship of the typhoid bacillus to certain cases. In the authors' case, the patient was a physician, aged fifty-seven years. Thirty years ago he had typhus fever, and, in 1885, he was ill for four months with what was diagnosed as typhoid fever. On July 10, 1899, he was obliged to take to his bed. Upon examination, a diagnosis was made of typhoid fever, with œdema and congestion of the lungs, the result of cardiac failure. On July 19th the physical evidences of a large, right-sided pleural effusion were found. Two quarts of a greenish-yellow opalescent fluid were aspirated with much temporary re-

lief to the patient. On July 24th and 30th, he was again aspirated, nine pints being removed in all. Upon bacteriological examination, the *Bacillus typhosus* was found in pure culture. Few cases have been reported as occurring early in the attack of typhoid fever; the third week of the disease seems to be the favorite time of onset. One of the most striking features of these pleuritis is the almost uniform character of the pleural exudate. In the majority of instances the aspirated fluid, as in this case, has been found to be purulent in character.

Asthenic Bulbar Palsy. By Dr. Charles W. Burr and Dr. D. J. McCarthy.

A Study of a Case of Gonorrhœal Ulcerative Endocarditis, with Cultivation of the Gonococcus. By Dr. August Jerome Lartigau.

Obstructive Biliary Cirrhosis. By Dr. William W. Ford.

Dorsal Dislocation of the Trapezoid. By Dr. John Glendon Sheldon.—This is an exceedingly rare occurrence, and the author has been able to find but one other instance in the literature. In neither case was it possible to effect reduction, though the usefulness of the wrist was unimpaired. The author believes, as the result of experiments on the cadaver, that there was a congenital weakness, absence of the ligaments, a maldevelopment of the carpal bones, or a combination of these conditions, which rendered it possible for an uncomplicated dorsal dislocation of the trapezoid to be produced.

Edinburgh Medical Journal, January, 1901.

The Borderland. By Dr. G. W. Balfour.—The author's article deals with the borderland between sanity and insanity, and he cites many interesting instances of modified mental derangement. Socrates, Van Helmont, Joan of Arc, Mohammed, and many others, furnish striking examples of the influence of delusions upon an excitable temperament, of the fact that hallucinations are often associated with an indomitable will and with considerable strength of intellect, and of the manner in which insanity has moulded history and influenced the fate of nations. Epilepsy often plays a part. Mohammed was epileptic from childhood; as in other epileptics, the fits were often followed by periods of prolonged unconsciousness, during which he had hallucinations of sight and hearing. In the realm of letters, some of the noblest works in literature have been produced by those who have all their lives dwelt in the borderland; Swift, Cowper, and Smart are examples.

Just as mental influence alone is of itself sufficient to give rise to stigmata and to other morbid affections, so the general prevalence of any special excitement, such as the English invasion of France in the days of Joan of Arc, may give rise to special forms of cerebral excitement quite apart from the presence of insanity, but which may also be variously modified by the co-existence of special delusions.

Experiences with the Medical Department of the Army in the South African War. By J. Chiene, F. R. C. S. Ed.—The author speaks of the lessons learned by him in the hospitals in South Africa under the following heads: Ambulance; anæsthesia; x-rays; hospital trains and ships; bullet wounds; injuries of the head; injuries of blood-vessels; injuries of the thorax and abdomen; medical cases; sanitation; burning *versus* burying; the work of the civil surgeon in South Africa.

Address Delivered to the Edinburgh Obstetrical Society, at the Opening of its Sixty-second Session, 14th November, 1900. By R. M. Murray, M. D.

On the Operative Procedures for Simple Fractures which Have Been Unscientifically Treated. By W. A. Lane, M. S.—The author began to operate upon cases of simple fractures in the belief that, owing to a shortening of the ties in the length of the limb by hæmorrhage and subsequent inflammation in fractures of the long bones, and especially in those of the leg, it is impossible by manipulation, except under special and rare conditions, when the factors resisting replacement are in abeyance, to restore to their normal relationship fragments which have been displaced off one another, whether the direction of the fracture is transverse or otherwise. The radiograph, introduced later, has verified in every detail, and in the most complete manner possible, the conclusions arrived at by the author. He reports twenty cases of operative treatment of simple fracture, in all of which excellent results were obtained. Several of the cases are illustrated by reproductions of radiographs, which are more than usually excellent.

Book Notices.

Comparative Physiology of the Brain and Comparative Psychology. By JACQUES LOEB, M. D., Professor of Physiology in the University of Chicago. Illustrated. New York: G. P. Putnam's Sons, 1900. Pp. x-309.

IN this volume are brought together numerous observations and experiments, a great number of which are due to the thoughtful ingenuity of the author himself, in support of the theory that many complex manifestations of life are nothing but reflexes. For these reflexes the central nervous system is not necessary. Irritability and conductivity, which are the essentials of the reflex mechanism, are the property of protoplasm and can act independently of nervous control. By means of the nervous system, reflex acts are refined and brought into harmonious relationship with each other. But the central nervous system itself is not necessary for their occurrence.

In the earlier chapters this theory is unfolded in regard to lower forms of life. The later chapters have to do with the vertebrates and to some extent with man. The theory is developed in a most suggestive and convincing way, and furnishes substance for much thought regarding all vital phenomena.

Thomas Sydenham. By JOSEPH FRANK PAYNE, M. D. Oxon., Fellow and Harveian Librarian of the Royal College of Physicians, etc. New York: Longmans, Green, & Company, 1900. Pp. xvi-1 to 264.

No work in this *Masters of Medicine* series has given us the pleasure that we have had in reading the life of Sydenham. This is not the result of the interest necessarily attaching to Sydenham only, but also of the very great skill with which the author has handled his subject. The book—and this can rarely be said of a medical biography—is a very readable and an exceedingly interesting volume. Sydenham's fame as a physician and his contributions to medical science are too well known to require enumeration here, but nowhere will one find their presentation more excellent than in the book before us, and, too, he will find great pleasure in the description of the stirring times in which Sydenham lived.

Histology of the Blood. Normal and Pathological. By P. EHRLICH and A. LAZARUS. Edited and Trans-

lated by W. MYERS, M. A., M. B., B. Sc.; JOHN LUCAS WALKER, Student of Pathology. With a Preface by G. SIMS WOODHEAD, M. D., Professor of Pathology in the University of Cambridge. Cambridge: The University Press, 1900. Pp. xiii-216. [Price, 5s.]

THIS little volume is a translation of a contribution to *Nothnagel's Specielle Pathologie und Therapie*. Many of our readers who are interested more particularly in the study of the blood are no doubt familiar with the work in its original form; for the benefit of those who are not, we may say that it is the most satisfactory presentation of blood histology and pathology with which we are familiar. It is exhaustive so far as facts are concerned, but it is pithy to the last degree. The fact that the translation was done under the guidance of Professor Ehrlich adds special value to the book, and we heartily commend it to the attention of our readers.

Encyclopædia Medica. Under the General Editorship of CHALMERS WATSON, M. B., M. R. C. P. E. Volume V, Herpes to Jaws. Volume VI, Joints to Liver. New York: Longmans, Green, & Company, 1900. Pp. vi-536; vi-562.

THE fifth and sixth volumes of this *Encyclopædia* are of an excellence equal to that of the four preceding volumes. Of necessity the condensation in a work such as this must be exceedingly great, and the entire subject of insanity, for example, is discussed in but little over a hundred pages, and yet this condensation in by far the greater number of subjects has been so skilfully done that one is not impressed by the slightest sense of incompleteness.

Pulmonary Consumption, Pneumonia, and Allied Diseases of the Lungs: Their Ætiology, Pathology, and Treatment, with a Chapter on Physical Diagnosis. By THOMAS J. MAYS, A. M., M. D., Professor of Diseases of the Chest in the Philadelphia Polyclinic, etc. Illustrated. New York: E. B. Treat & Company, 1901. Pp. 8 to 539. [Price, \$3.]

No doubt most of the readers of the *Journal* are familiar with the theories of the author of this volume concerning pulmonary tuberculosis. He seeks to prove that the generally accepted views of the scientific world are erroneous. The tubercle bacillus is not the cause of phthisis, but is found, according to him, as a secondary element. Pulmonary tuberculosis is primarily a neurosis, the pathological changes in the lungs being only secondary. The author goes even further, and insists that any agent, influence, or condition which undermines the integrity of the nervous system is likely to engender pulmonary phthisis or some other form of pulmonary disease. Pulmonary tuberculosis is not contagious, the tubercle bacillus having been found in the respiratory passages of healthy persons. Acute pneumonia is always affiliated with a disordered nervous system. The main treatment of pulmonary phthisis consists in the injection of nitrate of silver over the vagi in the neck. The author reports a large number of successful results by this method, and adds that but fifty abscesses formed as the result of over 2,000 injections. But it is significant that he did not neglect other and important means of treatment at the same time.

This is the gist of the contents of the book. There is no need of further comment, except to compliment the author upon having the courage of his opinions. The book is fairly well printed and is profusely illustrated.

Handbook of Practical Hygiene. By D. H. BERGEY, A. M., M. D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Easton, Pa.: The Chemical Publishing Company, 1901. Pp. 164. [Price, \$1.50.]

THE author has included in this little manual directions for the sanitary analysis of air, water, soil, and the principal food materials, and has added a chapter on ventilation and heating. The multiplication of books of this character shows the increasing interest taken by the profession in sanitary science. The present volume appears to be quite complete in its special field.

Disinfection and Disinfectants. A Treatise upon the Best-known Disinfectants, their Use in the Destruction of Disease Germs, with Special Instruction for their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. BRACKEN, M. D., Professor of Materia Medica and Therapeutics, University of Minnesota, etc. Chicago: The Trade Periodical Company, 1900. Pp. 85.

THIS is really a very valuable little work. In the first chapter the general field of disinfection is outlined, including the several applications of disinfectants to the living as well as those in use upon the dead. The potency of disinfectant drugs and methods is briefly stated in tabular form in the second chapter. In the third chapter the disinfectant drugs and procedures are taken up and considered in alphabetical order, and their relative advantages or disadvantages set forth. The fourth chapter treats of disinfecting apparatus and contains a fully illustrated description of formaldehyde generators. It is an exceedingly useful chapter. In the fifth chapter the proper disinfectant surroundings for patients ill of infectious diseases are described, and in the sixth the use of the rubber gown by medical attendants is considered. The forms of disinfection adapted to rooms, etc., are the subject of the eighth chapter, with the varieties of disinfection adapted to the various infectious diseases. This last chapter is of some length and is an excellent discussion of a very important matter. As a whole, the little volume is most useful and, presenting as it does the modern views upon disinfection, cannot but be of value. It is not exhaustive, it is true, but it is exactly the sort of guide the practitioner wants.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, etc. Assisted by H. R. M. LANDIS, M. D., Assistant Physician to the Out-patient Medical Department of the Jefferson Medical College Hospital. Volume I. Philadelphia and New York: Lea Brothers & Company, 1901. Pp. 4-17 to 440.

BEGINNING with a very moderate enthusiasm for this publication, we have found ourselves more and more its admirers as each new volume has been issued. It is not that the contents differ so materially from those of other annuals, or that the editorship, though of the best, is unique, or that the form of the production, though novel in its quarterly appearance, is the essential. There is a quality to the text, however, that, in our opinion, makes *Progressive Medicine* the best of its class. It is particular and detailed, it is exhaustive, it is authoritative, and it has a rare quality of continuity and sequence which the much-paraphrased annuals that have come under our

notice sadly lack. It is this quality, though the others are all to its credit, that makes this work so valuable.

BOOKS, ETC., RECEIVED.

A Text-book of the Practice of Medicine. By Dr. Hermann Eichhorst, Professor of Special Pathology and Therapeutics and Director of the Medical Clinic in the University of Zurich. Authorized Translation from the German. Edited by Augustus A. Eshner, M. D., Professor of Clinical Medicine in the Philadelphia Polyclinic, etc. Volume I. With 84 Illustrations. Pp. 7 to 628. Volume II. With 85 Illustrations. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 11 to 590. [Price per set, \$6.]

Eczema, with an Analysis of Eight Thousand Cases of the Disease. By L. Duncan Bulkley, A. M., M. D., Physician to the New York Skin and Cancer Hospital, etc. Third Edition of *Eczema and its Management*, entirely Rewritten. New York and London: G. P. Putnam's Sons, 1901. Pp. xii-368.

Essentials of the Diseases of Children. Arranged in the Form of Questions and Answers prepared especially for Students of Medicine. By William M. Powell, M. D. Third Edition, thoroughly Revised by Alfred Hand, Jr., A. B., M. D., Dispensary Physician and Pathologist to the Children's Hospital, Philadelphia, etc. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 5 to 259. [Price, \$1.]

Points of Practical Interest in Gynecology. By H. Macnaughton-Jones, M. D., M. Ch., Q. U. I., Master of Obstetrics (Honoris causa), Royal University of Ireland, etc. With 12 Plates. New York: William Wood & Company, 1901. Pp. ix-124.

Atlas of the Nervous System, including an Epitome of the Anatomy, Pathology, and Treatment. By Dr. Christfried Jakob, Head of the Pathologic Institute for Nervous and Mental Diseases at the University of Buenos Ayres, etc. With a Preface by Professor Dr. Ad. v. Strümpell, Director of the Medical Clinic, Erlangen. Authorized Translation from the Second Revised German Edition. Edited by Edward D. Fisher, M. D., Professor of Diseases of the Nervous System, University and Bellevue Hospital Medical College, etc. With 112 Colored Lithographic Figures and 139 other Illustrations, many of them in Colors. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 3 to 218.

Atlas and Epitome of Ophthalmoscopic Diagnosis. By Professor Dr. O. Haab, of Zurich. Authorized Translation from the Third Revised and Enlarged German Edition. Edited by G. E. de Schweinitz, A. M., M. D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, etc. With 152 Colored Lithographic Illustrations. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 3 to 85.

Anatomical Atlas of Obstetrics, with special Reference to Diagnosis and Treatment. By Dr. Oskar Schaeffer, Privatdocent in Obstetrics and Gynecology in the University of Heidelberg. Authorized Translation from the Second Revised German Edition. Edited by J. Clifton Edgar, A. M., M. D., Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College, etc. With 122 Figures on 56 Lithographic Plates, and 38 other Illustrations. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 3 to 315.

Atlas and Epitome of Labor and Operative Obstetrics. By Dr. Oskar Schaeffer, Privatdocent in Obstetrics and Gynecology in the University of Heidelberg. Authorized Translation from the Fifth Revised German

Edition. Edited by J. Clifton Edgar, A. M., M. D., Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College, etc. With 14 Lithographic Plates in Colors, and 139 other Illustrations. Philadelphia and London: W. B. Saunders & Company, 1901. Pp. 3 to 111.

Golden Rules of Aural and Nasal Practice. By Philip R. W. de Santi, F. R. C. S., Senior Surgeon to Out-patients, Westminster Hospital, etc. Golden Rule Series, No. IX. London: Simpkin, Marshall, Hamilton, Kent & Company, 1901. Pp. 3 to 87.

Handbuch der physikalischen Therapie. Herausgegeben von Dr. A. Goldscheider, a. o. Professor in Berlin, und Dr. Paul Jacob, Privatdocent in Berlin. Theil I. Band I. Mit 69 Abbildungen. Leipzig: Georg Thieme, 1901. Pp. xiv-563.

Twenty-third Annual Report of the State Board of Health of the State of Connecticut for the Year 1900. With the Registration Report for 1899 relating to Births, Marriages, Deaths, and Divorces.

Transactions of the American Pædiatric Society. Twelfth Session, held in Washington, May 1, 2, and 3, 1900: Volume XII.

Miscellany.

The Relation of Appendicular Inflammation to Diseases of the Uterine Appendages.—Dr. Albert L. Beahan (*American Gynecological and Obstetrical Journal*, February) relates four cases of appendicular inflammation in young unmarried women from seventeen to twenty-three years of age, and says that the gynæcologist may study with profit the relation of appendicular inflammation to his patient's diseases. Often the appendix has been found to be attached to the ovary and one or both disorganized. A limited experience will show that fact.

In the cases most closely observed a mean temperature of from $99\frac{1}{2}^{\circ}$ to $100\frac{1}{2}^{\circ}$ F. was found for several days during the menses, with a tender, swollen appendix. This seemed to clinch the diagnosis as being appendicular inflammation. The majority of cases have occurred in the unmarried, or in the married women who have not borne children. Why should appendicitis cause menstrual disturbances?" he asks. Does this inflamed abdominal tonsil produce similar profound systemic disturbances to those of its throat prototype? Is the cause to be attributed to the influence of torpor or paresis of bowel from the usual involvement of the peritoneal coat of the head of the cæcum? In severe chronic appendicular inflammation this seems probable. In milder cases, where adhesion or pus pockets are not found, a reddened splotch will be seen extending from the appendix upward to the head of the cæcum. The proneness of the female to colon and rectal accumulations with less discomfort than when this occurs in the male, is in evidence. Freeing the colon and lower bowel with cathartics especially directed to them, as with aloes, has always been an efficient method of obtaining an emmenagogue action of medicines. Reasoning from effect to cause, it may properly be argued that the full bowel induced by appendicular disease causes the menstrual irregularity. If so, constipation, gas-formation from indigestion, distention of food changes, self-infection in the bowel, nausea and vomiting, pallor, sallowness of skin, or a muddy complexion, loss of flesh, repeated sharp impressions of these attacks on the nervous system, with slight febrile attacks maintained for several days, make features that should be

apprehended and correctly interpreted. In this discrimination as to the diagnosis of appendicular inflammation in the female, it is necessary to exclude right-tube and ovarian disease by familiar methods. The removal of an appendix is never to be regretted when diseased. As its removal in this class of cases may be expected to correct the train of miseries associated with functional menstrual disorders, it should be done earlier than in probably any other form of appendicular disease. It seems to be borne out by the cases observed that the nervous symptoms of appendicitis in the female are out of proportion to the cause as measured by the same class of cases in the male, and to be as much pronounced as, or more so than, nervous manifestations of inflammation and abscess of the Falloppian tubes. This, probably, is because in appendicular inflammation the organ hangs suspended in the abdominal cavity and is affected by muscular and postural acts, while in the inflammation of the tube it is steadied more by its anatomical relations, and adhesions are a more frequent occurrence. And in diseases of the appendages, though menstrual pains are often severe, menstrual irregularities are not especially prominent. In recapitulation, the author says that a febrile disturbance during menstruation, with a swollen, tender appendix, obstinate constipation and gas-formation in bowel; painful, retarded menses, pain in lower segment of abdomen, especially in right side; loss of flesh, pallor, or muddy complexion, peculiar nervous symptoms, as irritability and exhaustion occurring in a more exaggerated form than is peculiar to the individual, make the probability of a diseased appendix very certain and its speedy removal imperative.

Cæsarean Section in Placenta Prævia.—Dr. G. M. Boyd (*Obstetrics*, April) gives the following indications for Cæsarean section, and draws the following general conclusions on the subject:

Indications for the Cæsarean Section: If the mortality of the Cæsarean section is less or even not greater than the mortality of the usual methods of treating placenta prævia, then for the child's interests it is indicated in certain cases.

We believe that it has a lower mortality, that it will not only save the child, but prove a most efficient method of rapidly checking hæmorrhage.

The bleeding from placenta prævia may appear at any time after the formation of that organ. The writer's earliest case was in a gestation of four and one-half months. Here the patient had bled to an alarming degree in spite of a careful tamponing of the cervix and vagina. Under ether a central implantation was diagnosed. It was necessary in the treatment of the case to first strip off and remove the placenta.

Early hæmorrhage is, however, rare. In at least eighty per cent. of cases it does not appear until after the viability of the child, and in about seventy-five per cent. it appears only a few days before term.

The maternal mortality in placenta prævia is, in part, due to the prolonged use of temporizing treatment. The patient loses a large amount of blood before active interference is instituted.

Conclusions: We would recommend an immediate examination under anæsthesia of all suspected cases for the purpose of (1) confirming the diagnosis; (2) determining (a) the variety of the prævia, (b) the size and position of the fœtus, (c) the condition of the cervix; and, finally (3), to facilitate the introduction of the cervical and vaginal tampon.

If the hæmorrhage appears before the viability of the

child, if the prævia is marginal, the cervix dilatable, the foetal heart absent, then version or forceps may suffice.

If, however, the child is viable, the prævia complete or partial, the cervix rigid, or the foetus transversely placed, then, in preference to other interference, the Cæsarean section would seem indicated.

The "Conscientious Objector" to Vaccination.—Dr. E. J. Steegman (*St. Mary's* [London] *Hospital Gazette*, March 31st), in a paper on The Prevention of Small-pox, referring to the recent provisional act suspending compulsory vaccination in Great Britain, says:

"Two important facts have already been brought out—the 'conscientious objector,' who was so fashionable about two years ago, has proved rather an unsubstantial person. For the first few months after the passing of the act he occupied a very prominent position, and took up much of the magistrate's time; now he is so scarce that his appearance forms a pleasant break in the monotony of ordinary police court procedure. Even in his palmy days he frequently applied for a certificate, and forgot to fetch it the next day, his objection not extending so far as paying the shilling demanded for it."

Jam Bricks.—According to the *Greenock Telegraph and Clyde Shipping Gazette* (Scotland) for April 16th, the latest thing in portable provisions consists of jam bricks. These are solidified jams which can be packed in oiled paper, and, when needed for use, the "hard, heavy cube, about two inches in size," is broken into pieces and emulsified with water, forming a valuable addition to portable rations.

Persistent Occipito-posterior Positions of the Vertex.—Brodhead (*American Journal of Obstetrics*, December, 1900; *American Journal of the Medical Sciences*, April, 1901) advises the use of forceps as rotators in persistent posterior rotation of the vertex during labor, and mentions the following conditions as those that should be present before the operation is undertaken:

The head should be as well flexed as possible; the vertex should be well down in the pelvis and preferably at the vulvar outlet; the membranes must be ruptured; the cervix should be fully dilated or dilatable; the bladder and rectum should be empty; last, but not least, the operator should be positive of his diagnosis of position. The patient is placed upon a table and a light chloroform anæsthesia used. The Tucker solid-bladed forceps has proved superior to any other. The blades are introduced laterally at the sides of the pelvis, each blade being rotated so as to occupy a position at the side of the head, after which the forceps is locked. Unless the operator is expert, it is thought safer to apply the forceps in the usual manner, the concavity of the pelvic curve looking forward, than to attempt rotation with the forceps in the inverted position. By carrying the handles of the instrument toward the thigh of the patient, toward which the concavity of the pelvic curve looks, the danger of laceration is much reduced. The operator then places two fingers upon the vertex at the sagittal suture, and when the uterus contracts it rotates the head partially, so that the sagittal suture is transverse. This is accomplished by rotating the handles of the forceps and carrying the handles downward and backward until the concavity of the pelvic curve faces the lateral wall of the pelvis. The head is then held in this transverse position until several uterine contractions and relaxations have occurred. The head is next rotated with the vertex anterior by rotating the handles, carrying them still further

backward and downward. In this way the tips of the blades are kept in the middle of the pelvis, and cannot lacerate the vagina. The head is held in the oblique anterior position for several moments to allow the body to rotate anteriorly. The forceps is usually removed at this time and reapplied in the usual manner and the operation completed.

If rotation cannot be accomplished except by the use of force the head must be extracted in the posterior position. If delivery can be accomplished by the natural forces the forceps is removed. The writer reports eight cases, in four of which the vertex was upon the left side and posterior, and in four on the right side and posterior. Seven of these women had normal pelves. One, a primigravida, had a justo-minor pelvis. The operation was uniformly successful in these cases. The author urges that the conditions essential are good flexion of the head, low position of the vertex, and attention to details.

The Relation of Thyreoid Gland to Conception.—Dr. E. C. Rankin (*Western Medical Review*, December 15, 1900; *American Gynecological and Obstetrical Journal*, February, 1901) reports two cases in which the thyreoid gland seemed to have a decided influence upon the organs of reproduction.

Case I.—A woman, forty years of age, the mother of two children, the younger sixteen years of age. She was placed on $2\frac{1}{2}$ -grain capsules of desiccated thyroids, three times a day, for exophthalmic goitre. Marked improvement in her general condition followed, although there was no perceptible diminution of the goitre. Three months after beginning treatment her menstruation did not appear, but as she had been irregular nothing was thought of it, and pregnancy was not suspected until she miscarried, four months later. This was due to general lack of vitality on her part.

Case II.—A woman of thirty-two, mother of one child eleven years old. Had suffered from exophthalmic goitre for several years before coming under the writer's care. Three grains of thyreoid, three times a day, was ordered, and improvement was soon evident. Three months later she became pregnant and was delivered at full term of a healthy child.

If the seeming connection between the administration of the thyreoid capsules and the subsequent pregnancies is correct, it might be used with advantage in certain cases of sterility.

Parasitophobia.—M. Dubreuilh (*Gazette hebdomadaire de médecine et de chirurgie*, April 11th) recently reported to the Medical and Surgical Society of Bordeaux a case in which a child having contracted the itch transmitted it first to his little brother, then to his grandmother. The latter, who was in every sense the head of the family, suffered intense irritation, though no trace of acari could be discovered. All the other members of the family became affected by the scratching mania, though but few if any bites could be found, and there was absolutely no trace of the parasite to be found. The author considers this as a case of psychic pruritus, the starting point of which was a parasite. In short, most of the members of the family succumbed to the suggestion emanating from the grandmother. M. Régis pointed out contagiousness as a special feature of this kind of phobia, while ordinary phobias were individual in character. He related an analogous case where a woman imposed her pruritus on eight members of her family. Dermatophobias developed always in a neuropathic soil but their prognosis differed in the hysteric and the neu-

rastrhenic. In the hysteric it was apt to be of short duration and to disappear under the influence of suggestion, while in the neurasthenic it lasted longer and was apt to become chronic. At the same meeting M. Méneau reported the case of a woman who, having been cautioned of the danger of contagion by the *Bacillus tuberculosis*, with which disease her son was affected, developed a phobia first of this micro-organism, and later of acari and various other parasites which, she asserted, fell into her hair.

The Concealed-sex Question again.—Many stories, mostly good, says the *West London Medical Journal* for April, have recently been told of a particular member of the surgical staff of one of the large London hospitals, but perhaps the following one is the best. While seeing his out-patients one day he captured a louse, and passed it round on a piece of paper for the instruction of his class. A facetious student, thinking to "score off" his teacher, gazed for a moment intently at the insect, and then with an assumed puzzled look gravely remarked, "Can you tell me, sir, whether this is a male or a female louse?" "I'm sorry I can't," was the incisive reply; "suppose you take it behind the screen and examine it."

Tuberculosis and Pregnancy.—Dr. Samuel Bernheim (*Journal of Tuberculosis*, October, 1900; *Woman's Medical Journal*, March) draws from his studies the following conclusions:

1. Pregnancy does not provoke tuberculosis fatally in the predisposed. Latent or previous tuberculosis is not invariably awakened by a single and a simple pregnancy. Gestation in those predisposed to tuberculous infection is the more likely to cause an awakening of latent trouble in proportion as the woman is younger. Hence the primary reason for forbidding too early marriages of girls whose debility threatens an ulterior bacillary invasion. Still further, it is necessary to exercise a long surveillance before permitting pregnancy in a tuberculous woman, as well as to be certain of her definite cure.
2. Tuberculosis is, moreover, aggravated by pregnancy in that the lesions become deeper and more extensive. A fatal result is almost certain in advanced cases.
3. Although single pregnancy may occur without grievous effect, in a patient the subject of latent tuberculosis, such is not the case with multiple pregnancies, which are almost always disastrous, even in women with curable phthisis.
4. The consequences of childbirth are particularly formidable to the tuberculous woman to whom nursing has been forbidden.
5. In all cases in which tuberculosis is aggravated in the first weeks of gestation, the practitioner is justified in inducing abortion. This is the rule adopted by many German and English physicians.
6. The influence of paternal tuberculosis on the progress of pregnancy may be considered as practically nothing.
7. Tuberculosis in the woman is frequently a cause of abortion.
8. After the confinement the newborn child should be removed immediately from the centre of infection. In thus placing it under good hygienic conditions, one has a much better chance of raising a robust and healthy subject.

Opacity of the Cornea (?Traumatic Keratitis) in the New-born.—Dr. Robert Jardine (*Glasgow Medical Journal*, April) reports the case of a male child, weighing nine pounds and a quarter, which was delivered with Milne-Murray's axis-traction forceps, "after a pretty stiff pull." The diagonal conjugate measured $4\frac{1}{4}$ inches, giving a true conjugate of $3\frac{1}{2}$ inches. The cord was pro-

lapsed. Artificial respiration to the child was necessary. The head had been grasped obliquely with one blade of the forceps over the right eye.

A few hours after birth the right cornea was observed to be opaque. The pupil could only be distinguished with difficulty. The surface lustre was somewhat diminished. The pupil reacted to light.

Dr. Ernest Thomson examined the eye on the 23d and 27th of January. On the second occasion the pupil had been dilated with atropia. He could not find any evidence of inflammatory action. On the 27th the opacity had markedly diminished. He was of the opinion that the opacity had been caused by the pressure of the blades of the forceps. At the age of ten days there was still distinct dimness of the cornea, though it had cleared up considerably.

There was no evidence of syphilis about the mother, and the child had not shown any at the time of report. Dr. Jardine has seen a very large number of cases in which there was quite as much pressure on the eye as in this one, yet he has never before noticed any opacity of the cornea. Very early in the embryo the cornea is opaque, and, he asks, may not this be a case in which there has been delay in clearing up?

A later note states that by a curious coincidence he has had a second case, in which there is no doubt that the opacity was caused by pressure. The patient had a scolio-rhachitic pelvis, with a true conjugate of $2\frac{3}{4}$ inches. The child weighed seven pounds, and was delivered with axis-traction forceps. There was a depressed fracture of the left frontal bone, caused by the promontory. The right eye was found to have an opacity of the cornea exactly similar to that in the first case, which was noticed immediately after delivery. The blade of the forceps had been over it. The left eye bulged somewhat, and there was a large hæmorrhage into the upper part of the orbit. The eyeball could not be examined. Three days later the clot was removed, and the eyeball was found to be intact, but the cornea was also slightly opaque.

In this case, he says, there can be no doubt about the cause. The left orbital plate is evidently fractured. The depression of the frontal bone has somewhat lessened, but it will have to be elevated when the child is a little older.

Alexander's Operation.—Dr. Le Roy Broun (*American Journal of Obstetrics*, April) emphasizes the following points:

1. Make a clean-cut incision down to the aponeurosis of the external oblique muscle—reaching the aponeurosis rather to the inner side of the ring than directly over it, thus affording an easier recognition of your location.
2. Bear in mind the presence of the superficial fascia, and that its density varies from such a thinness as to be hardly recognized to one of such thickness as to be readily mistaken for the aponeurosis not yet reached. The fibres of the aponeurosis are in large bundles, all running in one way. Those of the superficial fascia are finer and more closely woven.
3. Expose to a clear view both pillars of the external abdominal ring when distinctly marked. If indistinct, as in small rings and in instances of dense intercolumnar fascia, expose clearly the anatomical position. With this in view the pillars and ring can be recognized by touch.

Astereognosis.—Astereognosis, or the absence or loss of the faculty of recognizing foreign bodies, has been investigated by Professor F. X. Dercum (*Journal of Nervous and Mental Diseases*, November, 1900) in 114 mis-

cellaneous cases of nervous disease. From these studies the author concludes as follows:

1. It would appear that the loss or impairment of the spacing sense is the most important factor in determining astereognosis. It must be remembered, however, that astereognosis may exist though the spacing sense be preserved. In the single case of hemiplegia in which this was the case there was, however, a loss of location, a loss of the knowledge of the position of the fingers and marked secondary contracture.

2. Next in importance to the spacing sense appears to be the knowledge of the position of the fingers and ataxia of movement.

3. The mere preservation of the ability to perceive tactile impressions and the preservation of the pressure, temperature, and pain senses is insufficient to prevent stereognostic loss.

The author then asks if it is possible to draw any conclusions of clinical value. It is evident, of course, that astereognosis may be due to lesions of the brain, of the medulla (author's case), of the cord, and of the peripheral nerves. Further, astereognosis must be of two kinds, peripheral or central; that is, it must be due either to an interruption of the pathways, the peripheral nerves, or cord, by means of which the various sensory impressions reach the brain; or, these pathways being open, it must be due to some lesion of the cortex. In many cases astereognosis is undoubtedly cortical. This is undeniably the case in dementia; it was also the case in a brain tumor involving the cortex, reported by Dr. Mills and Dr. Keen. Now, if astereognosis is at times cortical and at times peripheral, are there any means by which the symptoms can be made of differential value?

Our present knowledge forbids a positive answer. It is not, however, impossible that it may be so employed. The various impressions received by the cortex from all of the various sources concerned in stereognostic perception must be combined in the cortex to give rise to the mental picture of the object felt. Given a case in which the various factors known to be important to stereognostic perception are all preserved and astereognosis nevertheless exists, it would be justifiable to infer that the origin of the symptom was cortical. Again, if with astereognosis there are specific or isolated losses, such, for instance, as a loss of the sense of weight, or of the position of the fingers, or ataxia of movement without the signs of peripheral nerve or cord disease, it would, other things equal, justify the inference of brain or cortical involvement. Indeed, such a loss would not merely indicate cortical movement; it would point directly to a special area of the cortex, namely, the posterior portion of the superior parietal lobule.

As to how much loss of the spacing sense depends upon nerve, cord, or brain involvement, it is impossible to say. It appears to be present in astereognosis dependent upon lesions in any of these situations, and yet the function implied by the spacing sense is probably purely cortical. If we analyze the cases of locomotor ataxia and multiple neuritis in which the spacing sense is lost, we find that the tactile sense is generally either impaired or retarded, so that in them the loss of the spacing sense may be merely the expression of a tactile hyperæsthesia.

Complete Transverse Sæptum of the Vagina Impeding Delivery; Urethral Coitus.—E. Rumley-Dawson (*Lancet*, December 8, 1900; *American Gynecological and Obstetrical Journal*, February) was called to see a primipara in labor at full term. In spite of strong pains,

no progress was made. The patient gave a history of regular normal menstruation up to the time of pregnancy. On examining the patient in the left lateral position, the index finger unwittingly and without causing pain passed directly into the bladder. Ocular examination showed that the urethral orifice was much dilated and the vaginal orifice small. One inch within the vagina was a thick, transverse sæptum, bulging with each pain. The cervix could not be felt. There was no opening in the sæptum, which did not occupy the site of the hymen. The sæptum was incised and the opening enlarged with the fingers. The cervix was found completely dilated, and a child was soon naturally delivered. The patient said that, when first married, intercourse had been difficult, and after a few months became impossible; then, later, it was found possible, but painful. The pain gradually subsided. There had been no incontinence of urine.

Dr. Dawson thinks that there is no doubt that the sæptum was congenital, and that up to and for a brief period after marriage there had been an opening sufficient to allow menstruation and impregnation. Coitus was probably at first in the vagina, when probably the opening in the sæptum became torn, and the freshened edges, in healing, united completely, shutting off the upper part of the vagina and the impregnated uterus. Urethral coitus had followed quite unknown to the woman, who was not aware of any abnormality in her genitals.

Malarial Disease in the Adult and the Infant Compared.—Dr. William A. Northridge (*Brooklyn Medical Journal*, April) makes the following comparison between the adult and infantile types of malarial disease:

<i>Adult Type.</i>	<i>Infantile Type.</i>
The tertian is the common type.	The quotidian is the common type.
Three distinct stages: cold, hot, sweating.	One distinct stage; the hot stage of fever.
The cold stage is well marked. Generally a chill is observed.	Often this stage is so slight as not to be remarked. The chill is generally absent, sometimes occurs. Convulsions and involuntary muscular contractions are seen at times. Most commonly, a pale, blue-lipped, pinched face is seen, with shrunken eyes. Or the child is drowsy, tired, listless, and yawns. Nausea and vomiting are common, occurring in about two thirds of all cases.
Nausea and vomiting not uncommon.	Fever is always present, and is often the only distinct symptom observed, and on its periodical recurrence, often depends the diagnosis. The temperature ranges very high, 104° F. to 108° F.
Hot stage. Fever is always present.	Sweating stage often absent, or very slight and not noticed.
Stage of sweating marked.	Periodicity marked.
Periodicity marked.	Anæmia marked.
Anæmia.	Spleen enlarged.
Spleen enlarged.	Nervous system often profoundly affected.
Nervous system not greatly affected.	Jaundice occasionally.
Jaundice occasionally.	The disease often presents peculiar manifestations.
The disease does not often present variations from its usual form.	

Types.—The quotidian is by far the most common type of this disease as found in the young child. Next to the quotidian, the tertian is the most common type, and all have noticed that sometimes, under treatment, the quotidian becomes a tertian as the disease becomes less severe. The author believes that the feeble resisting power of the infant accounts for the frequency of the quotidian type, rather than the double-infection theory of Thayer.

Original Communications.

ON THEORIES OF INHERITANCE, WITH SPECIAL REFERENCE TO THE INHERITANCE OF ACQUIRED CONDITIONS IN MAN.*

By J. GEORGE ADAMI, M. A., M. D., F. R. S. E.,

MONTREAL,

PROFESSOR OF PATHOLOGY, MCGILL UNIVERSITY.

QUESTIONS of inheritance at the present moment occupy a curious position in the minds of medical men and in medical literature. To judge from the medical press, we medical men are very Gallios—we care for none of these things. And yet, in family as in consulting practice, questions concerning heredity must and do continually present themselves. In attempting to arrive at a conclusion about a given case, we are bound to ask ourselves how far the frailties or follies of progenitors are responsible for the conditions found—how far the accidents or the sins of the individual. Each succeeding day you must have this question of possible inherited defect brought before you; constantly must you be forced not merely to inquire whether certain phenomena are matters of inheritance, but assuredly to recognize that this or other condition runs through all the members of a family and is an inherited weakness. And yet, although the lay reviews discuss the matter familiarly, and although perchance the charming partner you take in to dinner does the same, we scarce write about these things, save in connection with one or two branches of medicine, and when we do, I have no hesitation in stating, though it is a bold statement, that much of what is written is misleading.

Even in my own subject of pathology, treating as it does of the causes, the processes and the results of disease, in the discussion of which the laws of inheritance should obviously be carefully studied, if inheritance plays even a debatable part; turn to any of the text-books in our language and what do we find? A single page, or it may be but a single paragraph, is thought sufficient to introduce and to take leave of the subject. In short, from a concatenation of circumstances the medical study of inheritance is largely "taboo." Why is this?

It depends upon more than one factor. In the first place, while, as I shall point out later, the study of man is singularly well adapted for determining certain points in connection with inheritance, the fact that the generations of man follow each other at such relatively long intervals is against man being for most purposes a good subject for investigation. In the course of a long life the investigator can but study the characters of three, or it may be four, generations in one family, while influences acting upon the susceptible *fœtus in utero* in man, as in all mammalia, introduce complications. The basal

facts of heredity have to be made out in the lower animals, in which generations succeed each other with fair rapidity and in which the eggs are fertilized and from the first developed outside the body.

Unfortunately, too few of us are trained biologists; the curriculum of the past, as of the present, lays too little stress upon the value of a broad biological training as an aid in preparing us to discuss those special biological problems which constitute medical study. As a consequence the medical world in general has to depend upon the biologists proper—upon the zoologists and botanists—for its views upon heredity, and the pure and simple biologists have run riot in their lucubrations upon this subject. Do not think that I mean to belittle them or to indicate that we do not owe much to all the investigations and all the writings of the biologists of the last twenty or thirty years. The facts which they have elicited have been of the highest value. Without these facts we would be nowhere, but the contending theories elaborated by them (perhaps I should be the last to make any such criticism) have been fearful and wonderful, have started from morphological rather than physiological conceptions, and as a result have assumed shapes which would not disgrace the schoolmen of the Middle Ages. While they have appeared to collate and harmonize the facts known at a given moment, new facts have caused them to need modification, and the successive attempts to utilize the old bottles for the new wine, where they have not burst the bottles, have led them to assume most grotesque shapes. In fact there has been developed such a muddle that no amount of midnight oil and wet cloths bound around the temples permit the ordinary mortal to disentangle and follow the course of one theory.

This being the state of affairs, it is little wonder that we have passed by on the other side and have been unwilling to apply the theories of the biologists to the problems of medicine—and this all the more because the trend of these theories has been in apparently strong opposition to medical experience. Of all the workers of late years Weissmann has had the most influence upon biological thought, and his theory, if not accepted by all in its entirety—and if, indeed, now found unacceptable—has, nevertheless, profoundly affected the general consideration of this subject of heredity. That theory is very complicated, and with Weissmann's successive publications has not by any means become easier to follow or to epitomize in language devoid of technicalities. Still, if not every schoolboy, at least every educated man is supposed to comprehend the general tenor thereof and its main thesis or conclusion, that acquired characters—characters acquired by the individual—are not and cannot be transmitted to the offspring. To use Weissmann's own expression, "We maintain that somatogenic characters (characters originating in the cells and tissues of the body) are not transmitted, or rather, that those who assert that they can be transmitted must furnish the requisite proof. The somatogenic characters not only

*The first of a series of annual addresses under the auspices of the Brooklyn Medical Club, delivered May 17, 1901.

include the effects of mutilation, but the changes which follow from increased or diminished performance of function and those which are directly due to nutrition and any of the external influences which act upon the body. Among the blastogenic characters (characters originating in connection with the germ cells), we include not only all the changes produced by natural selection operating upon variations in the germ, but all other characters which result from this latter cause" (1). In natural selection is to be found the key of the phenomena of inheritance.

Now, up to a certain point, we as medical men are prepared to accept this teaching. We know from experience that acquired mutilations are not transmitted, we acknowledge that no clear and satisfactory examples of the transmission of mutilations have been brought forward. We can realize that the loss of an arm, for example, has no direct influence upon the germ cells of the individual, and that so these germ cells if fertilized will develop into the complete individual. But there is another class of phenomena specially interesting our profession which appears to give a direct lie to Weissmann's thesis. And it is, I think, this failure of the ruling theory to explain satisfactorily the phenomena in question which has been the main factor in making us as a profession not enthusiastic of late years to debate the subject.

For, accepting the theory, we must be prepared to deny wholesale the transmission of acquired defects of every order and give ourselves over to a most serious form of fatalism.

If an individual is from the first feeble-minded, that is not his parents' fault; it is due either to an unfortunate commingling of the ids, or ancestral plasms, composing the promiscuous ovum and spermatozoon from which he is derived or to characters which have come down to him from previous generations. If he, being diseased, begets feeble-minded children, he is in nowise to blame—acquired characters are not transmitted. Either those feeble-minded children are an accident—a spontaneous variation—or more probably they represent the summation of characters inherited from long generations. If a man or a woman becomes an alcoholic, it is not his or her fault, it is the result of inherited tendencies; and if the children of the same are of weak constitution or idiotic, again the parents are blameless—characters acquired by the parents are not transmitted, the characters of the parents must have descended to them. If a man is a criminal, again he is not to blame; criminality is atavism, is a reversion to an earlier state, is an inheritance of characters or features peculiar to primæval man. We are, so the popular translation of Weissmann's theory goes, the descendants of criminals, or at least at a certain stage our ancestors were of an imperfect and criminal type. And if criminality appears in the family, with imperfect formation of head and brain and low mental state, that is due to the fact that by the

fortuitous extrusion of certain ids from ovum or spermatozoon, the ids of the criminal ancestors have preponderated in the fertilized cell and the result has been that the individual has developed possessing criminal features. However much a man abuses his soma, or body, is of little moment; the effect upon the offspring is minimal.

I put this in strong language and baldly, and it may be urged that I exaggerate the state of affairs. I do not think that I do. I believe that in making this statement I but give expression to the general, if confused, ideas of the majority; nay, more, that I state the received conception of what Weissmann's theory means when applied to man and to abnormal inheritance in man.

Now, if there is one conclusion to which we think experience surely leads us as medical men, it is that the sins of the father do tend to be visited upon the children even unto the third and fourth generation. We think we see this demonstrated day after day. But Weissmann does not support the view. It is true that if we study Weissmann we find that he does not state this in so many words; he admits (2) that the germ plasm is not absolutely unchangeable, that the nutrition and growth of the individual must exercise some influence upon its germ cells, "but in the first place this influence must be extremely slight, and in the second place it cannot act in the manner in which it is usually assumed to take place." Certainly he does not make it clear that he believes in the distinct transmission of any order of acquired characters.

WEISSMANN'S THEORY.—Weissmann, I need scarce say, explains inheritance along the following lines: The germ plasm, the essential matter of the fertilized cell from which the individual develops, must in the process of fertilization come to contain portions of the germ plasm of both father and mother, brought to it by the nuclear material of the ovum and spermatozoon respectively, and the germ plasm of the father and mother must contain portions of the germ plasms of paternal and maternal grandfathers and grandmothers. And so, going back through a long series of generations, it follows, according to him, that representatives of the germ plasms of a long series of ascendants, or progenitors, are contained in the nuclear material of each ovum and spermatozoon. The constitution of a germ cell therefore may be represented, for purposes of inheritance, as made up of a vast number of ancestral plasms, or "ids," derived from the long line of progenitors.

I need not here explain his most ingenious demonstration of the means whereby at each successive act of fertilization a certain number of these ancestral ids are discharged, so that the ovum and spermatozoon each contain half the number originally present, and so that the number of ids in the fertilized ovum is kept constant. I need but point out, in passing, that by this process of reduction the set of ids discharged from one germ cell is by this theory held to be different from that discharged

from another germ cell of the same individual. And as the ids in two fertilized ova are not identical, as the same series of ancestors do not contribute to the germ plasm of the two, so it is that individual variation originates; the ids varying, the individuals controlled or developed by these ids tend to vary. So it is by this fortuitous commingling that spontaneous variation is apt to show itself.

Further, it has to be noted that when the ovum undergoes segmentation, and half of the nuclear material passes into one cell, half into the other, according to Weismann a certain definite series of these hypothetical ids passes into each cell and, according to the series entering each of them, so are determined the eventual characters of the tissues to which those daughter cells eventually give rise. The germ cells of the new individual become differentiated at a very early period, receive the full complement of the ids, and so carry on the whole series of properties inherited from the ancestors.

DIFFICULTIES IN ACCEPTING THIS THEORY.—This is a crude recapitulation of the main points of Weismann's theory. I have but mentioned those portions which especially bear upon my argument. To explain atavism, or the reproduction of characters in one generation which had not been recognizable in the previous generation but had been present in some earlier generations, you will see that the theory demands that some at least of these ancestral ids should have remained unchanged through a long period—it may be for centuries. For Darwin's case (3) of the return of features peculiar to the ancestral rock pigeon, brought about by crossing barbs, spots, and fantails, is clearly a case of atavism occurring after centuries of domestic breeding and loss of the features in question. So in such a case of atavism we must, in the terms of this theory, suppose that in the act of fertilization there is a summation and preponderance of just that series of unchanged ids which now in development lead to the bringing into evidence of the atavistic ancestral features. In other words, the theory demands that the ids must be singularly stable in constitution—that they grow and multiply, but retain the same structure.

But now Weismann has to admit that, under certain conditions, the ids are modified in their structure. This admission indeed is contained in the idea that the individual hypothetical ids vary in their properties; and as, if we trace back these ancestral ids to their common source, they must all originally have been identical in structure, we conclude that at the same time they are both stable and capable of change in constitution. Here indeed is the crux of the theory. How are we to define and realize for ourselves the limits of alteration? Natural selection cannot explain the alteration, unless we fall back upon the far-away hypothesis of multitudinous separate acts of creation in the beginning of things—affording a large number of distinct idioplasms—and even this hypothesis does not work out satisfactorily.

In the example already given of crossing of the old-established breeds of barbs, fantails, and spots, we must imagine that all the ids of each breed have been, in the germ cells of successive generations, exposed to almost identical conditions, and, as a consequence, modified along the same lines. Exposed to the same influences in the course of many generations, it is almost inevitable that all must become modified, for if there were any large number of unaltered ancestral ids contained in the germ cells it would inevitably occur that spots and atavistic forms would frequently present themselves. But this does not happen. Each of these varieties of the pigeon breeds singularly true. How, in short, are we to picture some of them passing from germ cell to germ cell through all the long years in an ancestral condition? Put to this test, the theory breaks down; we cannot picture the necessary conditions. It is, in short, an absurdity to regard the nucleus of the germ cell as containing a colony of what are, to all intents and purposes, separate and independent individuals, some of which have for centuries retained properties of one order, some properties of another, to conceive the germ cell as a colony of individual living beings, for this is what the theory demands (4).

DRIESCH'S DEMONSTRATION OF THE INCOMPETENCY OF THE THEORY.—But it may be urged, What is the use of all this argument to kill a theory already dead? For dead it is, so far as regards the ids, and Weismann's theory without the ids is like Shagpat without the identical. The brilliant observations of Driesch (5), abundantly confirmed as they have been by others, foremost among whom must be mentioned Professor E. B. Wilson (6), of Columbia, and T. H. Morgan (7), of Bryn Mawr, show that the conception is untenable. If in a segmenting ovum we find that normally each of the blastomeres, or primitive segmentation cells, gives rise to one special series of organs or tissues, but if nevertheless the ovum of sundry animals can have its cells shaken apart at the two-, four-, eight-, and even sixteen-cell stage, and each separated cell can be found capable of developing into an entire, if dwarfed, individual, then, obviously, each time the nucleus segments there is no passage into the daughter nuclei of particular series of ids destined to lead to the development of one particular region of the body. Rather, the variation in structure of the different tissues must be, to employ Driesch's words, "a function of their relative position" ("ihre prospective Bedeutung ist eine Function des Ortes"). The existence of these hypothetical ids is absolutely disproved. I dwell upon this theory because to-night I want more especially to discuss, on account of its importance from a medical point of view, this matter of the inheritance or non-inheritance of acquired characters. I hope that I have proved to you that the groundwork upon which the negative view is based is of proved unsoundness. The fact that a theory by which a position is supported falls through does not, it is true, afford proof that the position

is wrong, but when we find that the dictum of non-transmission of acquired characters does not wholly accord with medical experience, we may well ask: Can we gain a conception of the intimate nature of inheritance which is in accord with that experience?

INHERITANCE, TRUE AND FALSE.—My only regret is, that in striving to gain that conception, I shall have to inflict upon you yet another theory; my only apology, that that theory does appear to satisfy the conditions met with in man. First, however, it is necessary to lay down clearly what is not inheritance, for in medical writings and in ordinary medical parlance a terrible confusion prevails upon this point, and much that is certainly not inherited is commonly spoken of as being hereditary. There is, for example, no such thing as hereditary syphilis. There is congenital syphilis and there are, to employ Fournier's term, inherited "para-syphilitic" lesions, but "hereditary" and "congenital" are not and must not be regarded as interchangeable terms.

The confusion is due to the common error of regarding the individual as beginning his existence at the moment of birth and not until then, so that everything occurring before that moment is grouped in one category, everything after, in another. The chick, so to speak, is not a chick until it breaks open the shell; its status from the moment it ceases to be a new-laid egg—or, more strictly, the egg of commerce—until it emerges from the shell is not recognized in law, and fresh egg and chick are commodities of wholly different orders. But the individual existence of the chicken has already begun even before the egg is laid, and what is true of the chick is equally true of the human being. The individual begins the moment that fecundation is accomplished, the moment the nuclear material of the spermatozoon fuses with the nuclear material of the ovum and these twain become one. Compared with the event, birth is seen to be of secondary importance, for the intra-uterine association of the embryo with the maternal tissues is but one means employed by a restricted number of species to insure the satisfactory nourishment of the individual during the earlier stages of development. The recognition of these facts is essential for any serious study of the problems of human inheritance. Any disturbance due to influences affecting the individual from without while *in utero* is *acquired*. It certainly must not be spoken of as inherited; it is an ante-natal acquirement or is of *congenital* origin. That alone is inherited which is the property of the individual at the moment he becomes an individual, which is a property of the germ plasms from which he originates, or is produced by the interaction of those germ plasms. The biologist has no alternative but to define inheritance according to the principle here laid down, nor have we, dealing with a limited field of biology, the right to modify terms in general scientific use for our own convenience.

Now, when we find that syphilis or tuberculosis ac-

quired *in utero* during the later months is peculiarly severe and widespread in its manifestation, it is wholly unjustifiable to premise that the microbic germs of one or other disease could be present in either the conjugating ovum or spermatozoon, could pass into one or other of the blastomeres, in a latent condition, doing no harm to the developing ovum. The ovum would surely be destroyed or at the least be monstrous. Could it conceivably be present, it is more than debatable whether we could regard such a fortuitous inclusion as a part and portion of the germ plasm, and so a strict inheritance. However, I have already, at the Academy of Medicine in this city of New York, dwelt upon this subject (8). Suffice it to say that tuberculosis or syphilis of the new-born must, from every valid consideration, be an acquired congenital condition, not an inheritance. And, let me repeat, only that which is derived from the parental germ plasms is truly inherited.

It is to the germ plasm, the active matter in the germinal cells, and to the properties of that germ plasm that we must turn in order to gain our basis for any sound theory of inheritance. Weismann has done yeoman's service in emphasizing this fact. This germ plasm it is which conveys living matter from generation to generation.

GROWTH AND ITS ESSENTIAL NATURE.—Now, whatever life is, the fundamental phenomena or possession of living matter is the performance of work coupled with growth—the capacity manifested by that living matter to assimilate non-living matter of certain orders, to absorb it, to endow it with like properties, to convert it into matter like unto itself, into additional living matter, in doing which, work is performed. In other words, difficult as it is to conceive or picture to one's self the details of the process, growth is essentially a process of conversion, a *chemical process*, and any adequate theory bearing on the phenomena of growth must primarily be along chemical lines. We are ignorant of what it is in the structure of living matter which gives it those properties; we are, if possible, more ignorant of the physics of the process of growth, of the nature of the force which, acting upon or inherent in the constitution of living matter, leads to this continuous process of assimilation and conversion, and in our ignorance we are unable to separate the chemistry and the physics of the process; we must, that is, regard growth as a *property* of living matter. We must also for present purposes speak of the matter which is essential to and directly concerned in the activity of any one species or individual as a single substance which, following Nägeli, we can refer to as "*idioplasm*," and our conception of the individual or of the separate cell-units forming that individual must be that in each we have to deal with two constituents, the *idioplasm*, or essential and directive living matter, and the *cytoplasm*, which is in the strictest sense non-living, or certainly unable to exhibit the whole series of vital properties apart from the *idioplasm*, and which consists

of various formed elements developed and influenced by the controlling idioplasm, intimately connected therewith, it is true, but at the same time not an essential part of the same—the cytoplasm varying in its composition and nature under varying conditions which affect the idioplasm, the idioplasm under all conditions retaining certain cardinal properties.

That the constitution of the idioplasm is not absolutely but only relatively constant has also to be assumed. We are bound to recognize that it is capable of undergoing modifications within certain limits without loss of its cardinal properties, and this from the following reasons: Admitting, as we must, that the highest forms of animal and vegetable life have been evolved from the very simplest, that there has been an unbroken line of development of living forms from the simplest unicellular to the most complex multicellular; admitting also that in every act of reproduction, however simple or however complicated, the direct conveyance of the living matter of the parent into the offspring is to be demonstrated, that, in other words, the idioplasm of the primal living being has been continued on to successive and progressive generations, then we must admit that the idioplasm of the highest forms, judging from its powers of controlling and directing the development of the highly complicated organism, is something very much more complex than the idioplasm of the unicellular organisms; that in the course of evolution this has undergone successive accretions of properties, and this accretion of properties is the manifestation and accompaniment of increasing complexity of constitution of that idioplasm.

This idioplasm must be capable of modification, either by its environment or under the action of some law of progressive modification. The fact that there exist to-day forms of life practically identical in the main details of structure with those of remote geological ages is against the latter view; we must hold that environment determines changes in the constitution of the idioplasm.

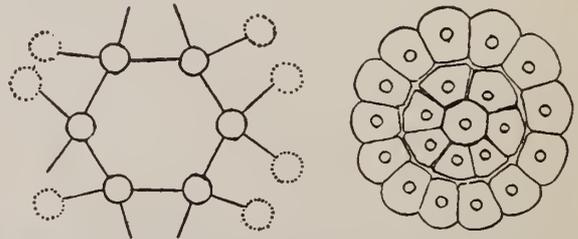

CHEMICAL THEORIES OF INHERITANCE.—THE ISOMERIC THEORY: It must now be asked, Can we imagine a chemical substance so constituted as to be capable of modification in its molecular constitution, and so in sundry of its properties, without undergoing complete change, without other properties being lost?

We can. If, as Professor Walker, of McGill, points out to me, such relatively simple bodies as lactic and malic acids are capable of existing in more than one form—as levogyrous and dextrogyrous and optically inactive modifications—and this with no obvious alterations in their chemical properties (though physically they show different actions upon polarized light, and physiologically we find that certain bacteria can act upon one and not the other form), then, certainly, the much more complex proteid material which would seem surely to be the basis of the idioplasm may present a very great

number of molecular arrangements, and each of these may be accompanied by slight differences in certain physical and physiological properties.

Certain recent observations have rendered this additionally probable. By our present method of conceiving and visualizing the structure of chemical substances we regard the carbon atom in the molecule as being situated at the centre of the tetraedron and as capable of linking four other atoms or groups one to each of the corners or apices of the tetraedron. A substance like malic acid having a single central carbon atom may, therefore, be built up in three ways, with the linked groups arranged in one relationship to each other, or in the reversed relationship, or the substance may be a combination of the two atomic forms. These are all the forms we can picture as existing according to this system. But now a fourth form of malic acid has been found which is more dextrogyrous in the polariscope than is ordinary dextrogyrous malic acid. And the salts of this new form of malic acid show slight but distinct variations, in solubility, etc., from the ordinary malates. If this is so, there may yet further be molecular modifications of such a relatively simple substance as malic acid, and *a fortiori* idioplasm may be capable of an enormous number of modifications.

THE SIDE-CHAIN THEORY OF INHERITANCE.—The mode of the atomic arrangement in the idioplasmic molecule may, therefore, in part, explain the variation in the properties of that idioplasm seen throughout the animal and vegetable kingdoms. I say in part, for if we assume that the structure of the individual is primarily the outcome of the structure and properties of the idioplasm, then for each different form of living being, nay, for each individual being, we have to assume a different atomic structure of the idioplasm. Or, otherwise, we have to assume that the modifications of this idioplasm are infinite in number. This, it seems to me, asks too much. The matter cannot be quite so simple. Each

molecular modification may play some part, it is true, but our conception of the structure and modifications undergone by the idioplasm must be more elaborate. We must, I think, formulate a theory of structure somewhat akin to that laid down by Ehrlich (9) in his now well-known theory of the nature of immunity. We can picture to ourselves the primitive idioplasm as composed of a mass of material each molecule of which is formed of a central ring, to which there can be attached side chains from which sundry side chains can be detached without the central ring being destroyed.

This conception, which upon first encounter appears revolutionary and opposed to our ordinary chemical ideas, is, after a little deliberation, recognized as being but a statement, in chemical terminology, of what has been for long years the accepted physiological conception of the nature of protoplasm. It is, if I may so express it, the fundamental—the essential—conception of the constitution of living matter; it follows logically and inevitably the postulate of assimilation and growth. Whether we agree, with the majority, to distinguish between the idioplasm and the cytoplasm of the cell, or prefer to speak simply of protoplasm, it must, I think, be recognized by all that we are bound to assume—for the process of assimilation and, again, in order to explain the variation in structure and properties of the various cells of the organism—that there is a central basal substance to which become linked, more or less permanently, or more or less temporarily, those other secondary substances which, not in themselves protoplasm, modify the constitution of the protoplasm as a whole. And these secondary substances, we see, are necessary for the full manifestation of the properties of that protoplasm. This conception is, I acknowledge, difficult to harmonize with the prevalent elementary conceptions of chemical action and chemical constitution, but it is, nevertheless, essential for the physiologist and unavoidable. What is more (for I do not pretend to be a chemist), I learn that it is not opposed to the more recent deductions of the chemists concerning the nature and properties of the more complex carbon derivatives. In other words, it is by no means heterodox from an advanced chemical standpoint.

Accepting this view, it is not necessary to regard the molecules of idioplasm as at all times presenting their completed structure, with every side chain attached. On the contrary, we are free to conceive the molecules being laid down and being transmitted in a relatively simple form, some of the side chains only becoming attached when the molecules are brought into certain particular relationships with their surroundings. It is not necessary, for example, to hold that already in the ovum there is idioplasm identical in structure with that eventually present in the muscle fibres or nerve cells developed from that ovum. Rather, we must hold that in the ovum there is one common idioplasm of simple type, to which, when distributed in the various cells derived from that ovum, different side chains become attached, according to the relationships assumed by those cells, so that the cells of different orders are controlled and formed around protoplasmic or idioplasmic molecules composed of those central rings plus varying series of side chains. Indeed, I am prepared to go further and to state that the idioplasm possessing its full complement of side chains must be regarded as *ipso facto* incapable of initiating cell multiplication.

I base this statement upon the fact, to which I have more than once called attention during the last few

months (10), that it is only cells which are undifferentiated, or which have reverted to a simpler less differentiated form, that are found to undergo division. Highly differentiated cells never multiply as such.

INHERITANCE IN UNICELLULAR FORMS.—If the primitive unicellular individual formed by this controlling idioplasm divides into two to form two individuals, each half will contain a portion of the idioplasm, and if the circumstances affecting the molecules of the new generation are the same as those affecting the parent forms, then this idioplasm will continue to assimilate to itself non-living matter and to endow it with its constitution and properties, and the individuals controlled by this idioplasm will correspond to the parent form and to each other.

But if the circumstances affecting the filial idioplasm vary from those affecting the parental, then these more unstable and loosely connected side chains will be the first to be influenced. The very act of assimilation (the surrounding medium varying in its composition) may lead to the substitution of other side chains, to slight variation in the composition of the idioplasm. And the cell or individual developed or controlled by the idioplasm will therefore vary from the parent form, while the products of division of this second generation, containing as they do this modified idioplasm, will exhibit like structural modifications. Here we have the simplest example of the inheritance of acquired characters.

There is, however, yet another property which we have to assume. It may be laid down as one of the great laws of biology that characters which are of the most recent acquirement are those which are most unstable, and are first lost; those which are oldest are the last to disappear. In man, for example, the first signs of generalized systemic weakness and imperfect development show themselves in connection with those properties which differentiate man from the animals most nearly allied, namely, in weakness and arrest of the higher functions of the nervous system, or, again, in susceptibility to certain specific diseases which are peculiarly apt to affect man, relative immunity toward which on the part of the healthy individual must be regarded as a comparatively recent acquirement. As my old teacher, James Ross, of Manchester, was the first, I believe, to point out, when there is progressive atrophy of the cells in the cortex of the brain, the first motor cells to show signs of that atrophy are those governing the muscles which differentiate man from other animals, namely, the opponens muscles of the hand.

Hence it has to be laid down that the attachment of these side chains, which are recently acquired, is relatively unstable, that such recent side chains are most easily detached, so that the idioplasm and the organism developed around that idioplasm are prone to return to their former condition or lose characters gained by recent progenitors. The more side chains become attached, the more complicated the structure, the more unstable

the equilibrium; hence the greater the liability to revert. As Professor Walker points out to me, parallel conditions are to be recognized in organic chemistry. The old-established view of the existence of "radicles" to a large extent admits this principle; certain central atomic groups in a compound are seen to be more fixed and not to undergo change when the attached groups are removed and replaced. Still more closely allied is what has been observed in connection, for example, with aniline. The composition of this is $C_6H_5NH_2$. Here the H atoms of the NH_2 group can be replaced by other groups, by methyl (CH_3) and ethyl (C_2H_5) groups, etc., and it is found under certain conditions that, in carrying out a series of these replacements, the last group attached is the first to be split off and replaced.

We see this principle in action in the lowest forms of life. Contrary to what Weissmann has laid down regarding parthenogenesis and asexual reproduction, it is comparatively easy to impress new characters upon the bacteria. By subjecting a growth of pigment-producing bacteria to the action of a temperature just below that which will cause their death, we can bring about a loss of pigment production, so that the rapidly succeeding generations are perfectly colorless, but gradually in the course of time the cultures made from the original (heated) tube regain the power of pigment production. This may be in two or three days, or, again, only after several transplantations at the end of two or three weeks, and when we remember that a bacillus divides and so forms a new generation in, on the average, something considerably less than an hour, it is seen that the acquired character may be impressed upon the race for some hundreds of generations (11). The more intense the alteration to which the bacillus is subjected, the longer and the more frequently the race is subjected to the altered temperature conditions, the longer it is before there is a sign of return to the normal. Translated into the terms of this theory, heat leads the idioplasm to have certain side chains, either modified or lost, and this modification or loss is inherited; but return to the normal environment leads the modified idioplasm in the process of growth and metabolism eventually to assume side chains of the same composition, the conditions of growth being similar to those under which the species originally acquired the side chain. Yet another solution, though it is one which I do not favor, is that not all of the molecules of the idioplasm undergo modification, a minority retain their original constitution, and, under favorable conditions, gradually come to preponderate.

SEXUAL CONJUGATION AND INHERITANCE.—How, next, does this theory bear upon sexual conjugation and its effects, for this also is met with in many unicellular organisms? I shall not take up the explanation of the development of male and female characteristics; this is too large a subject, but I would discuss how fusion of the idioplasm of two individuals affects inheritance. In that fusion we have a mixture of the two idioplasms, and,

as already pointed out, these idioplasms, as a result of the varying influences which have acted upon them, tend to vary in certain particulars in their constitution. This fusion must be either a mere admixture, so many molecules of one idioplasm becoming admixed with so many molecules of the other, or a true chemical combination. If we presuppose a mere mixture, we are led along the lines of Weissmann's theory and have to regard the idioplasm of the individuals of one generation as being composed of idioplasmic molecules or ids which have been passed down from the long line of previous generations. I have already pointed out the difficulties in which we find ourselves if we accept this view. The other view largely, if not entirely, removes these difficulties, nor does it introduce any fresh crop of serious difficulties.

We may regard, then, the idioplasms from the two parent forms as undergoing a true chemical combination,* the resultant idioplasm of the new generation being in truth a new idioplasm not possessing the identical properties of that of either parent, but being intermediate, tending in its characters and constitution toward the constitution of either one or the other according, it may be, to the number or chemical activity of the molecules of one or other parent entering into combination. Weissmann supports his view by pointing out that for a certain period the maternal and paternal materials in the chromosomes of the daughter nuclei remain distinct, and reaches the bold and utterly unsupported conclusion that when the chromosomes fuse to form the irregular network pervading the nucleus, their constituents nevertheless remain distinct and sharply separable from those of the other chromosomes. But we have no evidence, in the first place, that the chromosomes alone contain the idioplasm, that chromatin and idioplasm are identical. Everything points to the fact that the idioplasm is contained in the nucleus, but we cannot with certainty advance further. It may be that the chromatin is but the cystoplasmic framework, the mechanism, as it were, by which the idioplasm is distributed.

If the germ cells of both parents possess certain loosely attached or unstable side chains of more recent acquirement, which are of like nature, there is no sufficient reason why the protoplasm of the offspring should not also possess them. We can thus realize how it is that abnormal features present in both parents may be equally or more prominent in the offspring. But in general we must recognize that, the parents varying in different directions, the tendency of conjugation is to preserve the mean, to bring about an approach to uniformity in the constitution of the idioplasm of successive generations of one species exposed to like influences.

I need scarce say that in these higher unicellular organisms which present conjugation the cell already presents a nucleus, and that everything indicates that this

*It may be asked, How can identical or almost identical substances undergo true chemical combination? Physicists nowadays freely recognize this possibility. Thus, everything points to the molecule of water being, not H_2O , but $3H_2O$: numerous other examples might be brought forward.

nucleus is the controlling and directive body in the cell—that it is the nuclei which undergo conjugation—and that, in short, we have to recognize that the idioplasm of the individual is contained in the nucleus. It is by no means necessary to conceive that the whole of the nuclear material is idioplasm, or that the whole of the idioplasm enters into chemical combination with the molecules derived from the conjugating germ cell, molecule for molecule. I mention this in passing to indicate that it is not necessary to assume that when polar bodies are extruded the material forming them is identical with the idioplasm of the remaining nuclear material. The difficulties in explaining polar bodies and the reduction of the nuclear substance are no greater by this than by Weissmann's theory. The exigencies of time demand that I should not enter in detail into the consideration of these subjects. Rather, I must give the broad outlines of the theory and pass on to consider inheritance in multicellular organisms.

INHERITANCE IN MULTICELLULAR FORMS.—Every multicellular organism arises from a single cell, the fertilized ovum, itself in all sexually produced forms the result of fusion of a male and female cell, of the ovum and spermatozoon. Studying the method whereby this one cell gives rise to the adult multicellular organism, we see that by successive acts of division this one cell gives rise to all the cells of the body. In the course of this process its nucleus divides and redivides, and that in such a way that at each division like portions of the nuclear material pass into each daughter-cell. This regular distribution of nuclear material affords a sound ground for believing that there is an equally regular and uniform distribution of idioplasm into each cell. Now, I have already pointed out the value of Driesch's observations in overthrowing Weissmann's contention that there must be a qualitative difference in the idioplasm distributed to the daughter-cells. We have absolutely no ground for believing in any such qualitative difference; on the other hand, it is a legitimate inference that the idioplasm is modified by its environment. To take the simplest example—a multicellular organism composed of a spherical mass of cells. Those cells which come to form the peripheral layer of the individual are subjected to a series of reactions quite different from the series telling upon the centrally situated cells, and it requires no stretch of the imagination to predict that in the process of assimilation and growth on the part of the idioplasm of these outer cells, that idioplasm tends to be altered in its constitution as compared with the idioplasm of the centrally situated cells. So that the results of division of the peripheral cells, if retained in the same environment, will tend to produce the characters impressed upon the parent cells, and so that, if this subjection to the special set of conditions is continued and impressed upon this order of cells for a sufficiently long period or with sufficient intensity, even when pressed or passing into other environment, the cell generations will

retain these modified conditions, so that, for example, cells of mesoblastic origin will tend to maintain characters different from those derived from epiblast, and this whatever the ultimate position of the cells in question.

In fact, as a first law, we may lay down with Driesch that the structure of the cells in a multicellular organism is a function of their position, and this because the position of the cell determines the modification undergone by its idioplasm. As a second law we may lay down that the greater the change impressed upon the idioplasm of these cells and the longer that idioplasm is subjected to the conditions inducing this change, the more permanently will the daughter-cells exhibit the peculiar alteration in the idioplasm, with consequent modified structure wherever they find themselves in the economy. We have, in short, to recognize that two orders of forces determine the structure of every cell in the body: (1) The previous influences acting upon its idioplasm and causing it to be of a particular chemical constitution; and (2), the position in which the cell finds itself and the forces acting momentarily and immediately upon its idioplasm. Or, briefly, these two series of forces are inheritance and environment, and inheritance and environment determine the constitution of the idioplasm and the structure of the cells.*

Following this line of thought, we can understand how it comes to pass that the body cells and the germ cells in the higher and more complex organisms become so sharply divided, how it is that the body cells are no longer able to reproduce the whole organism. Their idioplasm has become altered in certain directions to such an extent that it is able, under favorable conditions, to divide and reproduce cells like Nature, but the very extent of the modification it has undergone has taken from it that constitution or structure which is necessary to allow it to reproduce each and every order of cells which together form the individual. The germ cells, on the contrary, undergo no such extensive changes in constitution—as a function of their position in the organ-

*To the worker in bacteriology the hesitancy on the part of biologists in general to accept environment as a most important factor in originating variation is almost incomprehensible. Nothing is more remarkable in the study of the lowest unicellular forms of life than this effect of environment in bringing about changes in character, changes which not only tell upon a limited series of generations (as I have already pointed out), but are permanent in their nature. By no means, save altered environment, could Hansen (12), taking isolated yeast cells or "spores" (100 per cent. of which, when cultivated under ordinary conditions, gave rise to spore-bearing forms) and subjecting these to the highest temperature at which growth could still occur, obtain a race or variety of yeast which now, after twelve years, has continued to grow under ordinary conditions without once developing spores. By no means save altered environment is it possible to explain Vincent's conversion of the absolutely harmless potato bacillus or, again, the *Bacillus megatherium* (by long-continued sojourn within closed collodion capsules in the peritoneal cavity of animals) into forms profoundly pathogenic, and fatal to rabbits, mice, and guinea-pigs in the course of a few hours (13).

The argument that phenomena observed in unicellular organisms cannot be applied to multicellular organisms is, to say the least, a severely strained argument. The extent to which environment acts as a factor may, it is true, be diminished in these, but surely it cannot be regarded as being eliminated and rendered negligible.

ism, their idioplasm as it grows and is distributed into the successive germ cells retains its fundamental constitution with but little alteration, and when these germ cells are discharged they and their idioplasm, brought into like relationships to those affecting the parent germ cells, undergo the like series of developmental changes, and reproduce the whole series of cells, tissues, and organs characteristic of the species to which they belong.

In the terms of this theory, therefore, inheritance essentially depends upon the chemical constitution of the idioplasm or the life-bearing or biophoric protoplasm of the germ cells, not upon the number of the separate ids or biophores or ancestral plasms or pangenes contained in the idioplasm; and variation, whether slight and individual or extensive and leading to the production of species, is ultimately the expression of modification in the constitution of that idioplasm brought about by environment. Whereas Weissmann's theory lays stress upon relative fixity in the constitution of the idioplasm, this theory admits freely the capacity for change in structure of the same. So long as the surrounding conditions are unaltered the idioplasm is unchanged; alter these conditions and the idioplasm is liable to variation in constitution.

ATAVISM.—Lastly, in regard to atavism and reversionary degeneration of the cells of the individual, this conception of the idioplasm with attached side chains, which are more firmly or more loosely attached, affords a perfectly adequate explanation. The more advanced the organism the greater the number of these attached side chains, the more recent the attachment of a side chain the more unstable that attachment. As a consequence, any profound disturbance will, according to its intensity, tend to cause the loosening and removal of the more unstable side chains in general in the order of their stability of attachment. And as the structure of the individual and of the individual cells is the expression of the constitution of the idioplasm, of the germinal idioplasm, and of the idioplasm of the individual cells, so according to the intensity of the disturbance will there be greater or less reversion to an earlier stage in the developmental history.

Let us now apply this theory to those special problems which I have referred to as being of peculiar interest to us as medical men. Can acquired defects be transmitted? In seeking to answer this question, at least three orders of phenomena have to be recognized and distinguished. These are:

1. THE NON-INHERITANCE OF ACQUIRED MUTILATIONS.—To these I have already referred. We cannot conceive of the direct transmission of identical lesions of this order from parent to offspring. At most we can conceive of the possibility of indirect effect where the mutilation is extensive or affects organs playing an important part in general nutrition. If there is impoverished general nutrition we can understand that this can

affect the germ cells along with the other cells of the organism, that the lack of due assimilation or the excess of sundry internal secretions which, in consequence of lowered general metabolism, have been imperfectly neutralized, by telling upon the blood and lymph, may lead to modification of the idioplasm of those germ cells, with the possible resultant imperfections in the growth of the fertilized germ, everything depending here upon the combination of the modified germ plasm of the mutilated individual with that of the other parent. If the number of molecules of this other idioplasm or the constitution of the same is adequate to counteract the loss of side chains in the idioplasm of the mutilated individual, there may be no recognizable effect. Or, on the other hand, the effect upon this latter idioplasm may be so serious as to lead to inherited defects in the offspring. But clearly these defects will be of a different order and a more generalized type; they will not be identical with the mutilation. There will be no direct transmission of acquired defects of this nature.

2. THE INDIRECT TRANSMISSION OF ACQUIRED DIATHESIS.—With reference to diathesis, this also may be laid down, that acquired disease and the effects caused by disease cannot *in general* be transmitted in such a way that the offspring presents lesions identical with those produced in the parent, though it has to be recognized that there is the possibility of modification in that offspring due to the parental disease. There is the possibility of a certain amount of transmission, not of the identical local lesion caused by the disease in the parent, but of a modified or impaired condition of the germ plasm. We must recognize that constitutional disease, by leading to disturbance in the activity of important organs, tells not only directly upon these organs, but secondarily upon other organs. It leads, for example, to an altered condition of the blood and so to altered nutrition of all the cells of the body. Among other cells, the germ cells may be directly affected, their idioplasm modified and the offspring directly influenced. Conditions affecting the parents are capable of influencing and modifying the descendants. It is this which is forcibly brought home to us in our medical work. It is changes of this order which are almost inevitably neglected by the biologists, for they are not within their ken. The changes brought about in the tissues by what is essentially chronic intoxication may be so slight as to be inappreciable. Microscopical examination may reveal nothing; only by their physiological effects can their existence be recognized. It is in the study of these conditions and their effects that medicine can afford the most valuable aid in the matter of inheritance.

All infectious diseases are intoxications. If a parent is the victim of syphilis, it is obvious from febrile and other phenomena not merely that there are local toxic phenomena at the foci of growth and multiplication of the germs of the disease, but that the toxines pass into the general circulation. They may produce no imme-

diate structural changes in the cells and tissues, but we have evidence that the protoplasm of various tissues is affected, although the results of the disturbance may only show themselves after long years. Indeed, the only explanation we can give of many remote effects of syphilis is this, that during the active period of the disease there has been a change wrought in the constitution of the cells of sundry tissues, slight and subtle, it may be, but sufficient to lead to premature exhaustion of the idioplasm of those cells. It would be absurd to argue that the immature germ cells lie absolutely dormant in the organism. They need nourishment, they assimilate; they are thus also apt to absorb circulating toxins, and their idioplasm must be affected in this act. Hence, while syphilis as such is not inherited, the toxins of the disease must be regarded as prone to set up molecular disturbances in the germinal idioplasm, and the offspring may show, not syphilitic lesions, but parasymphilitic lesions—various forms of arrested and imperfect development of different tissues due to the intoxication and therefore modification of the germ plasm while still a portion of the parental organism.

Parental intoxication, therefore, is seen to be capable of directly affecting the germ cells, and if there is no direct transmission of the effects of such intoxication, certainly there are indirect effects. In demonstrating the truth of this statement, it must be freely admitted that conjugation and intra-uterine existence introduce grave complications. In fertilization it is obvious that the idioplasm of the sound parent may largely neutralize the defective constitution of that of the diseased parent, while we have constantly to guard against ascribing to defects in the germ plasm conditions acquired during intra-uterine life. If the mother is the subject of any toxic state (to use the broadest possible phrase), not merely may the ovum be directly affected prior to fertilization, but in the course of foetal existence the organism of the offspring, deriving its nutrition as it does from the maternal blood, is liable to be affected and disturbed by circulating toxic substances and the development of the different tissues to be correspondingly influenced. The only conditions we can safely study are those in which the father is the subject of disease or intoxication, the mother exempt. Nor is it easy in cases of infectious disease, or even in frank intoxications such as the alcoholic, to be perfectly sure regarding maternal exemption.

Paul's observations, however, upon the effects of lead poisoning afford a most convincing demonstration along the required lines (14). Plumbism is peculiarly a trade disease. It particularly affects those following certain occupations; thus often the male wage-earning member of the family is alone exposed. Studying the history of thirty-two pregnancies in which the father was the victim of saturnine poisoning, the mother free from the condition, Paul obtained the following remarkable statistics:

Twelve resulted in death of the foetus before term (eleven abortions, one child born dead).

Twenty children were born alive, of which eight died during the first year; four died during the second year; five died during the third year; one died later; two alone were found to be living, one aged twenty years, the other only twenty-one months.*

Eighty-two resulted in abortion.

Four resulted in birth before term.

Five resulted in children born dead at term.

Twenty resulted in viable infants which died before the completion of the first year.

Fifteen resulted in children dying between the first and third years.

In connection with the effects of paternal syphilis, Fournier (15) has contributed strong evidence along the same lines, pointing to the great frequency of arrested development of various orders, from intra-uterine death to infantilism. To his statistics objection may be made that certain of the infants recorded by him probably suffered from the actual disease acquired *in utero*, secondary to local infection either of the placenta or of the membranes. Discounting this possibility in a certain proportion of cases, his figures still remain very remarkable. But what is needed is a more searching study of these cases of defective children, the offspring of a healthy mother and an infected father, to make sure that we are dealing with parazyotic as distinct from zymotic lesions. In connection with the subject, Gheorghiu, studying malformations, has pointed out the remarkable frequency with which there is, on inquiry, obtained a history not merely of the mother, but of *either* father or mother, having been a sufferer from acute or chronic infectious disease at the time of conception (16).

3. THE DIRECT TRANSMISSION OF ACQUIRED CONSTITUTIONAL STATES.—In the above-mentioned series of phenomena we have dealt, as I say, not with the direct transmission of acquired conditions, but with the deleterious influence leading to general defects of development and due to the action of toxic agents upon the germ cells prior to conception. Can we advance further and see evidences of direct transmission of acquired constitutional states? I think we can.

If, for example, an animal acquires immunity to a disease, we are convinced that the process of acquirement is a chemical process; that the action of the toxin of the disease has been to set up certain molecular changes, certain alterations in the composition of the cell substance, so that that cell substance now responds in a different manner when brought into contact with the toxin; and once this modification in the cell substance is produced, the descendants of this cell retain the same

*Legendre, in his essay in Bouchard's *Traité de pathologie*, Vol. I (which in the first place directed me to Constantin Paul's admirable article), gives a table of 141 pregnancies which I cannot find in the paper referred to. Possibly this is from a later article by the same author, but the proportion of abortions as given by him is so much larger that I doubt if this can be the case.

properties, that immunity to one special disease is not merely a momentary, but is a more or less lasting, state of the system. It is true that it tends not to be permanent; we see that, where it is attainable, the more prolonged and the more severe the changes set up in the process of immunization, the longer it lasts; we recognize, further, the action of the law that properties of most recent acquirement are soonest lost, and that there is a distinct tendency for the condition, or acquired state, of the cells to pass away. Nevertheless, we admit that inheritance of the acquired condition has to be granted in the case of the body cells in this connection. Here, again, if these processes obtain in connection with the body cells we must logically admit their action in the case of the germ cells. The idioplasm of body and germ cell is of like origin and must be susceptible to like influences.

The toxins circulating in the blood of the individual undergoing immunization must also affect the germ cells; they must acquire immunity, and the individuals developed from them must, subject to the law of loss already noted, have the same properties. Now, as a matter of fact, this transmission of acquired immunity has been occasionally noted, where, for example, both parents (rabbits) have been rendered immune to the *Bacillus pyocyaneus*, the offspring have been found more refractory to pyocyaneus infection, but in general the observations have been negative. This, as I have hinted, is only to be expected on account of the easy detachment of, if I may so express it, newly acquired side chains. It is, however, legitimate to suppose that successive immunization through several generations will cause the new side chains to become more and more fixed, and that racial immunity is brought about by these means, a view more probable than the alternative of mere "survival of the fittest."*

Conversely, in those cases where immunity is not developed, in the case of chronic conditions like tuberculosis, we can, along these lines, comprehend how the toxins weaken the germ cells along the same lines as they weaken the general tissues of the body, and as the resistance of the body in general to a special microbe and its products becomes less and less, so also the idioplasm of the germ cells becomes less and less resistant, and so from parental disease the offspring gains a peculiar susceptibility to one special disease. So that, in short, from disease acquired by the parents a particular diathesis is developed, a special susceptibility to the particular form of disease.

Here Weissmann would make the somewhat subtle distinction that we are not dealing with the direct transmission of acquired parental defects—that the toxins produce these results not by acting on the body cells, but

*It goes without saying that where both father and mother are immunized through successive generations and the fetus—and its germ cells—acted upon by the maternal blood and milk, the development of acquired inherited immunity should become yet more assured.

by direct action on the germ cells—that the inheritance is blastogenic, not somatogenic (17). This is a sorry and almost Jesuitic play upon words. Let us grant that they are of blastogenic origin; they are nevertheless of individual acquirement. The individual consists of body plasm and germ plasm, and whether the defect tell primarily or secondarily upon the germ plasm of the individual, we have here examples of conditions acquired by the individual being transmitted to the offspring.

But we can go further. Exogenous and bacterial intoxications are not the only intoxications; we recognize yearly more and more the existence of states of truly endogenous intoxication, auto-intoxications—of disturbed states of the constitution due to disturbances in glandular activity or to excess of certain internal secretions or of the substances ordinarily neutralized by the same. Such disturbances, acting on the germ cells, would be truly somatogenic.

If gout and the gouty diathesis are, as many hold them to be, of the nature of true auto-intoxications, if in a given percentage of cases (in France twelve per cent., according to Bouchard) the gouty state shows itself in those giving an absolutely negative history of gout in their progenitors, then we are at liberty, I think, to regard the gouty diathesis as an example of truly somatogenic acquirement of an inherited and inheritable constitutional state.

Defect in bodily metabolism has led to intoxication of the germ cells, and the offspring show a peculiar liability to be the subjects of intoxications of the same order. Here what is transmitted is a constitutional state, and that constitutional state may manifest itself in more than one way, but no one will deny that this is truly inheritance of an acquired condition.

We must, therefore, I hold, be prepared to admit the possibility of the transmission in inheritance of certain orders of acquired constitutional conditions—we must see that it is not necessary, with Weissmann, to deny strenuously the inheritance of each and every order of acquired defect, and that along the lines of some such theory as that outlined this evening we gain a fuller harmony between theoretical considerations regarding the nature of inheritance and the facts as they present themselves to us day after day.

CONCLUSION.—Within the time at my disposal it has been impossible to touch upon many aspects of inheritance which interest us as medical men—upon spontaneous variations and their transmission, upon inbreeding and marriage of consanguines, upon degeneration as distinct from atavism, upon the particular problems of inheritance of nervous conditions, to mention but a few. It seems to me, however, that this conception of the properties of idioplasm is adequate to bring together and harmonize the facts we possess concerning all of the above-mentioned conditions.

Let me conclude with Weissmann's apology: "Hypotheses, even when not absolutely right, may be of value

in advancing our knowledge, if only they are relatively right, *i. e.*, when they correspond with the state of existing knowledge. They are like the feelers which the short-sighted snail stretches forth on its darkened path, testing this way and that, and withdrawing them and altering the route so soon as they come across any obstacle." (18).

I must, gentlemen, ask your forgiveness for bringing before you a subject so far outside the line of general medical thought, and for having inflicted on you so much that is theoretical. That was not my intention when I sat down to prepare the paper. I had intended to indulge in the main in a destructive criticism, to point out how Weissmann's and allied theories fail to satisfy certain orders of conditions presenting themselves to medical men; but as I proceeded with the task it became obvious that mere destructive criticism was valueless, that it became imperative to present an alternative theory which for many months—I may truly say years—had been simmering within me, unexpressed.

APPENDICITIS PERFORATIVA IN IRREDUCIBLE RIGHT SCROTAL HERNIA, WITH A REPORT OF A CASE.

By O. THIENHAUS, M. D.,

MILWAUKEE.

It is almost a proverb in medical science nowadays that we learn more from one case in which we have faced disaster than from many others in which the patients made a so-called uneventful recovery. This old truth, together with the paper of Tacke, Epityphilitis im Bruchsacke (1), in which he has collected twenty-eight cases and adds one observation of his own, has induced me to contribute here briefly, out of 514 operations up to date, with four deaths (one is cited in the *American Journal of Obstetrics and Diseases of Women and Children*, Vol. xlii, 1900, No. 4), the above-named case, which, though it has many analogues, especially since the development of the pathology of the processus vermiformis in this country, with its enormous up-to-date literature, still seems of sufficient importance to warrant publication.

F. H., a laborer, sixty-seven years of age, was stricken suddenly with an attack of fever, vomiting, and sharp pain in his right inguinal hernia, which had made its first appearance seventeen years before. At the beginning irreducible, it became strongly fixed to the hernial sac eight years subsequently, steadily gaining in size. Four years previous, a somewhat similar hernia had appeared on the left side. Examining the patient, I found the radial artery in a state of sclerosis. There was slight emphysema of the right lung, with sibilant rhonchi over both lungs. The abdomen was somewhat retracted in the region of the stomach. There was an irreducible hard scrotal hernia on the right side, of twice the size of a man's fist, over which the skin was somewhat reddened and felt hot to the touch. In the depths of the hernial tumor, just in the neighborhood of the testicle, but distinctly separated from it, a hard mass as thick as a man's thumb and about five centimetres in length could be distinctly outlined. I demonstrated this condition to my assistant, at that time, Dr. Nitzelnadel, and made the suggestion that this mass was the appendix lying with the distended cæcum in the hernial sac. On the left side a reducible scrotal hernia as large as a man's fist was encountered. During the operation (assistant, Dr. Nitzelnadel) I found, after opening the hernial sac, the gray-colored cæcum adherent to the sac on all sides, imbedded in pus and faecal matter. Just below and attached to it in its whole length was lying the appendix, perforated in its anterior portion. In the opening of the perforation a black foreign body, of the form of a prism and about two and a half centimetres long and one centimetre thick, was encountered, which, upon minute examination, could be classified as a siliceous schist stone. I removed the appendix and opened the cæcum to obtain free drainage. The next day the patient became comatose, and death followed from sepsis the same evening.

An appendix, as well alone as together with omentum and small and large intestine, situated in a hernia, chiefly an oblique inguinal hernia, is not so uncommon

a phenomenon in literature. Yaia (2), for instance, stated at the Thirteenth Congress of the Italian Surgical Society in Turin, 1898, that Colzi, of Florence, among 1,586 cases of operation for hernia by himself, had found twenty-seven hernias of the appendix, six of which were incarcerated hernias. In all the twenty-seven cases the appendix showed symptoms of, and was in a chronic state of, folliculitis. Ritter von Hoffman (3), of Albert's clinic in Vienna, says that in recent years, among 250 Bassini operations for radical cure, the appendix has been found nine times in the hernial sac. Catellani (4) operated in Tricomi's clinic on 420 hernias, and found the appendix in four, either alone or with the cæcum. Most important statistics of appendicular hernias are, furthermore, given by Klein (5), 22 cases; Brieger (6), 24 cases; Baiardi (7), 51 cases; Briangon (8), 14 cases; Eccles (9), 29 cases; and Tacke (1), as cited, 28 cases.

It has been pointed out by many authors concerning the frequency of appendicular hernias that males are noticeably in preponderance, and that the majority of cases are congenital oblique right inguinal hernias in children and juveniles. This finds its natural explanation if we take into consideration the development of the descent of the testicle on this side and its abnormalities. Lockwood (10) has demonstrated that occasionally muscle fibres and peritoneal bands are formed extending from the appendix or the cæcum to the gubernaculum Hunteri. Jonathan Hutchinson, in his remarkable and very readable paper before the sixty-seventh annual meeting of the British Medical Association, On the Vermiform Appendix in Relation to External Hernia (11), illustrates a case of the latter type from an original dissection in the London Hospital Museum.

As another cause of appendicular hernia, there have been considered preceding attacks of appendicitis (*vide* Battle (12)), and the theory has been brought out that an appendix transformed by repeated attacks into a stiffened and erectile organ, which state of affairs we encounter sometimes in interval operations, may protrude into a peritoneal pouch in the neighborhood of the internal hernial ring, for example, the diverticulum Nuckii.

To render justice to a discussion of this hypothesis would extend this paper beyond its outlined limits. I should, however, like to state here briefly that a very long appendix or a swollen and erectile organ, together with perhaps a natural great mobility of the cæcum (long mesocæcum or mesenteriolum ileocæcale commune (13)), may explain many phenomena to which I shall refer later.

When an appendix has once descended into a hernial sac, there is abundance of opportunity for it to be subject to inflammation produced as well by *external* causes, such as traumatism, manipulation on the part of the patient, a truss, etc., as by *internal* reasons, such as kinking and bending of the organ with stagnation of fæcal matter and bacteria. In regard to the truss, Gross (14)

cites a case in which double perforation of the appendix was due to ulcers caused by the pressure of the truss.

It is easily understood that many cases of appendicitis in the hernial sac have been mistaken for incarcerated and strangulated hernias and have been treated accordingly; and that under such conditions experiments in taxis, when the error was not detected early enough, have oftentimes been promptly followed by the death of the patient, is not at all surprising. Even during an operation on a hernia it has sometimes been found very difficult to recognize an appendix, especially when the surrounding circumstances of the dislocated organ have produced changes in its appearance and shape which may make it almost unrecognizable. When the appendix has no mesentery (Hutchinson believes that this is the case in from forty to fifty per cent.), and cystic dilatation has taken place, as described by Weir (15), Wolff (16), Gutmann (17), Mayland (18), Wood (19), and others, it may be mistaken for a diverticulum Meckelii in the hernial sac. If covered with nodules of fat, it may become annoying to make a differential diagnosis between a part of the omentum or a lump of prevesical fat, which oftentimes calls our attention to the bladder as an inmate of the hernia and the appendix. In other instances the swollen organ may render the decision between an appendix and a tube without the ovary, lying in the hernial sac, difficult. This latter condition, doubted for some time because of the anatomical relations of the ovary to the Fallopian tube, is nowadays by many specimens established as a fact, and Morf (20), describing a case of his own, has, in a careful selection, collected a total of twenty-four observations (thirteen inguinal, ten crural, one obturator) of undoubted cases of hernia of the tube alone without the ovary. In one instance, cited by Jordan (21), tubal pregnancy was found in the hernia. Sometimes the appendix may be attenuated in such a manner that it looks like a whip, and has been mistaken for a band or a spermatic cord. Treves has put a specimen of whip-like appendix, found in the sac of a left inguinal hernia and covered with nodules of fat, in the museum of the Royal College of Surgeons in London (*vide* illustration in Hutchinson's article). In other cases we find what was supposed to be the hernial sac filled with pus, the origin of which was at first appearance difficult to detect. The later appearance, however, of a perityphilitic exudate or abscess has shown the appendix as *vera causa et sedes morbi*.

Not long ago I operated in a case in which the untying of the differential diagnostic knot as to whether I had to deal with a retrocæcal abscess following infection after an operation for incarcerated hernia or an abscess caused by appendicitis with or without any relation to the operation, was almost impossible. The woman was confined to her bed with great distention and pain in the abdomen for three months after an operation for what was supposed to be an incarcerated right femoral hernia. The house physician of the hospital in which the first

operation was performed informed me that during the operation nothing but a lump of fat could be encountered in the hernia, which was removed, and a radical operation performed by the use of silk ligatures. About ten days afterward an abscess opened over the external femoral ring, the abdomen became distended with gas, and sharp pains set in, chiefly in the right iliac region. When I first saw her, three months after the first operation, two tumors, each of the size of a child's fist, could be outlined in the depths of the meteoristic abdomen, in the region of McBurney's point. On the external femoral ring two fistulæ secreting pus were found. Diagnosis: Two exudate tumors in the retrocæcal region. The questions which immediately arose were, first, whether or not these exudate masses were caused by an ascending process, produced by infection after the operation for hernia, which would have indicated that the fistulæ were in communication with the exudate tumor; second, whether the abscess was caused by an appendicitis following the operation for incarcerated hernia; or, third, whether or not the appendicular abscess was caused by injury of the appendix during the operation. Nature, however, helped to disentangle the knot and made an operation for the perityphilitic abscesses unnecessary. Eight hours after the woman's transportation to a hospital for operation the two exudate tumors disappeared by perforation into the cæcum, and for two days stinking pus-like fæcal matter was discharged by way of the rectum, after which the abdominal distention subsided. On operating for the fistulæ, which, however, did not yield, four days afterward, three silk sutures were removed as *causa peccans* of the pus secretion. No communication with the abscesses above was found. The relation to the appendix, however, could not be decided upon, and I must leave that *sub judice*. Perfect recovery occurred after a feverish convalescence. That buried silk sutures, when infected, are oftentimes the cause of a good deal of trouble and after-work, is so well recognized that it is almost an old story out of a new book.

At the close of my paper I should like to ask the indulgence of the reader for a few moments' therapeutical consideration of appendicular hernia, which I should like to briefly review as follows: First, as it is almost a law nowadays that in all gynæcological abdominal operations, especially in cases of inflammation of only the right annexa, the appendix demands strict observation and removal, if necessary in a manner illustrated by Howard Kelly (22), so the same rule must be followed in operations for hernia, and when we take into consideration that, as already cited, Colzi found in all cases of appendicular hernia the appendix in a state of chronic folliculitis, I probably do not go too far when I say that in every case of hernia in which we find the appendix as an inmate it must be removed according to the old rule *in prophylaxi est salus ægroti*. Second, where appendicular inflammation is present in a hernial sac, operative procedure has to be advised immediately, and in case of in-

carcerations under such conditions every palliative method, such as ether refrigeration, though known for a long time but recently recommended at a meeting of the Paris Academy of Medicine (23), or attempts at taxis, are entirely objectionable procedures. Third, in cases of appendicular abscess in a hernial sac or gangrene of the appendix, resection and free drainage without reduction is the appropriate treatment, and if incarceration exists, this has to be relieved and the peritoneal cavity walled off carefully by iodoform gauze. The radical cure of the hernia, of course, has to be delayed, under these conditions, till the signs of inflammation have subsided.

ELEVENTH AND WELLS STREETS.

MUSCULAR ACTION OF THE ARTERIES.*

BY ANDREW H. SMITH, M. D.,

NEW YORK.

I WAS glad to see the announcement of Dr. Daland's paper on Arterial Spasm, because I think that in considering changes in the vessels we often limit our view too much to what takes place in the other coats of the arteries and fail to consider fully the crippling that comes to the

*A contribution to the discussion of Dr. Judson Daland's paper on Arterial Spasm, read before the Section in General Medicine of the New York Academy of Medicine, April 16, 1901.

muscular structure when the intima and the fibrous tunic are diseased.

Recent studies seem to show that physiologically the whole arterial tree, to its minutest branches, is only a continuation of the left heart and, therefore, is essentially a muscular organ. Each pulsation is produced by a wave of muscular contraction beginning in the left auricle and passing through the ventricle into the aorta and along each subdivision until the capillaries are reached.

This is a positive muscular action which follows behind each separate volume of blood that leaves the ventricle and urges it forward, the fibres on the distal side of the blood wave relaxing at the same time to permit its passage.

The action is analogous to that of the circular muscular fibres of the œsophagus, which contract above the descending bolus of food and relax below it. The stimulus to this vascular peristalsis is found in the distention of the vessel by the passing wave of blood. This stimulus is reflex in its character, and is derived from the sympathetic nerve fibres distributed to the vessels.

The importance to the circulation of this muscular action in the vessels can scarcely be over-estimated. Its efficacy as an aid to the heart in the propulsion of the blood is evident at once. At the same time the mechanism is a delicate one, and liable to be impaired whenever the physical properties of the vascular walls undergo a change.

The effect of calcification in destroying the elasticity of the vessel and making its walls rigid is what we think of first in this connection. The mechanical obstacle which this condition necessarily presents to the forward movement of the blood is of the first importance, and this is enhanced when fibrosis of the outer coat is added. But in the latter case the effect goes beyond the mere impairment of elasticity. The delicate fibres of the vasomotor system distributed to the muscular coat are stretched and compressed by the greatly thickened and condensed outer coat through which they pass. In this way the innervation is impaired or, it may be, cut off at certain points. The resulting impairment of muscular action throws just so much more labor upon the heart, which in pronounced cases is compelled to force the blood unaided through the entire round of the circulation.

That hypertrophy of the ventricle should follow is only an illustration of a general law proportioning muscular growth to muscular activity.

The case presented by Dr. Daland is unique as illustrating the effect of a known definite irritant in the blood to cause an intense and protracted arterial spasm. It throws a powerful side-light upon the action of certain poisonous, or at least irritant, substances which are retained in the blood under conditions of renal insufficiency. Just what capsicum did in a high degree and for a brief period in Dr. Daland's case is done in a minor degree by excrementitious substances constantly remaining in the circulation.

This condition of chronic arterial spasm not only increases the labor of the heart directly, but also cripples the heart by depriving it of the aid it should have from the rhythmic muscular action of the arteries.

HYPERACIDITY
(SUPERACIDITY, HYPERCHLORHYDRIA,
SUPERACIDITAS CHLORHYDRICA);
A CLINICAL STUDY.

BY H. ILLLOWAY, M. D.,

NEW YORK,

FORMERLY PROFESSOR OF DISEASES OF CHILDREN, CINCINNATI
COLLEGE OF MEDICINE AND SURGERY; FORMERLY VISITING
PHYSICIAN TO THE JEWISH HOSPITAL, CINCINNATI;
FELLOW OF THE NEW YORK ACADEMY OF
MEDICINE, ETC.

(*Continued from page 885.*)

IN so far as my personal experience is concerned with the twenty-three cases of hyperacidity forming the basis of this paper, I did not in twenty-one cases* observe that the stomach contents, extracted under the conditions already named, differed in any way as to either quantity, amount of solid matter, or appearance from the stomach contents of the cases tabulated as normal, extracted under like conditions. The variations noted in the normal cases were also found here. In some, more of the solid matter ($=\frac{1}{4}$ the height of the contents of the glass, an ordinary tumbler, in which they were received from the tube), in others, less ($=\frac{1}{8}$ th the height of the contents of the glass); in some presenting the appearance of an emulsion (the bread particles all well suspended in the whole volume of the fluid), in others, the solid matter not so well suspended, and the fluid looking more its original appearance; in some, the quantity discharged through the stomach-tube smaller, in others larger (ranging from 60 to 120 cubic centimetres).

In the twenty-third case the stomach contents answered fully as to quantity, and very nearly as regarded character, to the descriptions of Strauss and Schuler.

John K., a German, aged forty-four, married, the father of one child, height 5 feet 3 inches, weight 145 pounds (formerly 157 pounds), a square-built, large-boned man, worked in a wine cellar. Formerly he had been quite a beer-drinker. He had worked for years in a beer-bottling establishment and consumed, while at work, ten or twelve bottles a day in the summer and six or eight in the winter. More or less frequently he would drink more beer in the evening when out or in the company of friends. Occasionally, when he did not feel well or was much troubled with phlegm (and this occurred mostly in the morning on arising), he would take a drink of whiskey. Some time before he had changed his situation and was now working in a wine cellar. With this change had come also a change in his habit of drinking; he had quit beer and drank wine through the day, though, as before, taking beer when he went out in the evening. Lately, however, he had cut down his drink

*As to one other case, see note, page 882.

very much—no beer, no whiskey, only a little stout and wine. He smoked one cigar a day, in the evening; Sundays, three cigars. Up to three years before he had always been well and able to eat or drink anything and at any time. Since then his stomach had troubled him more or less, though he had had periods of absolute freedom when he did not know that he had a stomach. Latterly the intervals of freedom had been less frequent and of shorter duration, and the periods of gastric disturbance longer continued. For the last few weeks he had lost appetite and had been dieting himself on soups. For a week he had hardly been able to eat anything, and had taken only a little soup or a soft-boiled egg (for the different meals). He felt nauseated all the time, but did not vomit; occasionally a little mucus was thrown up. He had cramps in his stomach, setting in about two or three hours after meals, about 10 A. M. and around 3 P. M. The cramps were at times so severe as to cause him to vomit. Formerly he had had much pressure in his stomach—a sense of weight—and this would pass up into his throat and go into his back; since the cramps had come on, he had not felt this. His bowels were regular, and he slept well. The face was very pale, but with rather a yellowish tint to the pallor; the cheeks were inclined to be flabby; the lips were of a light-bluish color and the palpebral mucous membrane was decidedly blanched. The expression of the countenance was rather dull.

The distance from the xiphoid cartilage to the umbilicus was 9 centimetres. From the upper border of the left sixth rib the gastric resonance extended down to the ninth rib; there was the same condition over the left epigastrium, and there was resonance along the left border of the thoracic arch down to the ninth rib, where there was flatness. In the median line there was resonance from the xiphoid cartilage down to within two centimetres and a half of the umbilicus, where the tone changed and became duller. There was no splashing. After he had drunk seven ounces of water there was still no splashing. The liver was normally located, with no enlargement perceptible, no change in shape, no tenderness over it. The spleen was normal.

On the following day the test breakfast of Ewald and Boas was taken in the office. After an hour the tube was introduced, and I secured 265 cubic centimetres of stomach contents. On standing, it settled in three layers: 1. A slight layer of froth. 2. Fluid (light tea-color). 3. At the bottom, a layer of bread divisible again into two layers—the upper finely worked up, soft, pap-like; the lower, coarser, more like grits. The layer of bread, altogether, was very small. Reaction to blue litmus + Reaction to Congo + (characteristic) Reaction to phoro. gluc. van. + Reaction to resor. + (strong). Total acidity, 69. Free hydrochloric acid (after Mintz), 35.

As is seen from the foregoing history, this person has been addicted for years to the consumption of large quantities of alcoholic liquors, differing therein from the subjects of all my other cases. Though it is true that no organic changes were discovered, still it has had its influence, as is made evident by the anæmia. From this and from the absence of the particular phenomenon under discussion in all the other cases, it appears to me not unreasonable to conclude that the great amount of stomach contents—the hydrorrhœa gastrica, to speak with Strauss and Roth—stands in closer relationship to this alcoholic habit than it does to hyperacidity.

The Specific Gravity.—According to Schuler, the specific gravity of filtered stomach contents extracted from normal stomachs, under the conditions already named, ranges from 1.016 to 1.020. A specific gravity above 1.020 is considered a certain indication of subacidity. Examinations made by me in ten instances of filtered stomach contents extracted from fairly normal stomachs, as shown by the total acidities and the proportions of free hydrochloric acid, have given the following results:

TABLE C.

Case.	Total Acidity.	Free HCL.	Sp. Gr.
1.....	58	26	1.020
2.....	46	10	1.022
3.....	55	27	1.020
4.....	69	43	1.022
5.....	57	26	1.022
6.....	51	22	1.022
7.....	58	32	1.018
8.....	42	12	1.030
9.....	62	26	1.026
10.....	46	04	1.026

It would thus appear from the foregoing table that the normal range does not run down so low as 1.016, and that it may be higher than 1.020. A specific gravity of even 1.030 is no proof positive of subacidity, as shown by the proportion of free acid found in this case.

In hyperacidity, according to Schuler, the specific gravity ranges from 1.006 to 1.010. The results obtained by me in five cases were as follows:

TABLE D.

Case.	Total Acidity.	Free HCL.	Sp. Gr.
1*.....	69	35	1.009
2.....	74	40	1.010
3.....	56	33	1.012
4†.....	52	13	1.030
5.....	61	35	1.015

Here, again, our table shows a higher range. However, taking it as a whole and comparing it with Table C, the conclusion appears justified that, as a rule, the specific gravity of the filtered stomach contents is lower here than is ordinarily found, though exceptionally a high degree of specific gravity may be met with. This corroborates the findings of Strauss, and confirms the statement of Schuler.

As to the causes of the variations in the specific gravity, as noted both in Table C and Table D, that is a matter that requires further investigation. They cannot be dependent upon the acidity alone, as Strauss and his collaborators would seem to imply. This is readily demonstrated: In Case 4, of Table C, with free acid 43, we have a specific gravity of 1.022, and in Case 2, of the same table, with free acid only 10, we have the same

*The case recorded in detail above.

†These filtered stomach contents, contained in an Erlenmeyer flask, tightly closed with cotton wool, stood for two days in a cool place before the specific gravity was taken. I noticed no change therein, and the reaction to Lugol's solution was strong. I have deemed it proper to note this here.

degree of specific gravity, 1.022. In Case 5, with free hydrochloric acid 26, the specific gravity is 1.022, while in Case 9, with the same proportion of free acid, it is 1.026. Again, in Case 9, with free acid 26, the specific gravity is 1.026, and in Case 10, with free hydrochloric acid only 04, it is also 1.026. The more striking demonstration is this: In Case 9, with free acid 26, the specific gravity is 1.026, and in one case of hypo-acidity recorded in my case book, absolutely no reaction to Congo being obtained, it is also 1.026—not a whit higher.

Furthermore, and more particularly in view of what has been said above as to the quantity of stomach contents, the other question naturally presents itself: Why is the specific gravity lower in cases of hyperacidity than in others? This also cannot be answered now and must be left for future study.

Greater Amount of Amydulin Present.—My observations on this point confirm the statements of Schuler. However, it is not by the reaction to Lugol's solution alone, as Schuler would have us do, that this can be judged. There is really no difference in the color reaction between the stomach contents derived from a hyperacid and those from a normal stomach. Where a difference can be noted is in the period of time required for the colors to disappear; thus, while in the filtered stomach contents from a normal stomach the colors disappear *in toto* in from ten to fifteen hours, it takes from twenty-four to thirty hours for their complete disappearance from stomach contents from a hyperacid stomach.

It would, then, appear from the foregoing, that the two factors last considered—the lower specific gravity and the greater quantity of amydulin present—are characteristics that apparently pertain to hyperacidity alone, and are, therefore, undoubtedly of much value, in a confirmatory sense, in establishing, in conjunction with other phenomena to be considered, the diagnosis of this morbid condition. But until they have been further studied and demonstrated beyond question in a very great number of cases, they cannot be considered sufficiently pathognomonic to base a diagnosis upon them alone.

Subjective Symptoms.—These are mainly manifestations of irritation of the terminal points of the sensory nerve fibres in the stomach, and are of varied character.

Occupying the first place among these is *pain*, pain in the stomach. This may range from merely a sensation of great pressure in the epigastrium to an acute gastralgic attack. In the majority of cases it is a pain that is midway between these two extremes that is complained of. It has certain peculiarities that are characteristic:

1. It is not a continuous pain. It comes on at certain periods of the day, and in the intervals there is complete freedom therefrom.

2. It is altogether dependent upon the ingestion of food, is called forth thereby, but not at once: that is, it does not supervene in the course of the meal or at the conclusion thereof, but some two or four hours later (ac-

ording to the character of the meal), at a time when the digestive act has been nearly completed and much of the chyme has already passed out.

This is readily understood when we bear in mind that it is the free hydrochloric acid that is the cause of the pain. At the periods referred to, the food masses ingested, having become thoroughly saturated with the gastric juice, can take up no more, and the acid of the excess secreted thus remains free and irritates the gastric mucous membrane, and through it the terminals of the sensory nerve filaments. The fact that much of the chyme has already been ejected into the duodenum I hold to be a not unimportant factor in the production of this irritation. The free hydrochloric acid remains thereby to a great extent undiluted, and the coating to the mucous membrane which the chyme would otherwise in a measure afford is removed.

3. The character of the food and the quantity thereof are of no little influence. It is much more readily provoked and then felt more severely by the amylacea, by warm decoctions (teas, coffees), by thin soups than by solid nitrogenous matter, and more readily by a light meal than by a full one. It is a fact that at times these very patients will eat inordinately large meals—rich in nitrogenous substances—without the least disturbance being felt thereafter. I have heard such patients, who had suffered much and dieted long, express their surprise that so abundant a meal, which they had taken by my direction (as a test) and on my responsibility, should have agreed with them. The explanation already given applies here also.

Of the twenty-three cases observed by me, *pain* was complained of in thirteen. It was in all nearly of the same character, "a dead, dull pain with a gnawing sensation," as one of the most intelligent of my patients described it. In twelve of these cases the pain came on about the hours of 10 and 11 in the morning—in the working people who breakfasted earlier, at about 10, in the merchant who breakfasted later, at about 11—and at about 4 to 5 in the afternoon. All these patients ate very light breakfasts—coffee (or tea) and bread and butter, or coffee (or tea) and bread and butter and a little oatmeal; only one ate a small chop. All except one partook of a light luncheon at noon, ranging from a cup of coffee or milk and bread and butter, or cup of coffee and a sandwich, to a slice of roast beef and a glass of ale; the exception ate his dinner at noon, but as he had but twenty minutes in which to eat, he did not get away with a heavy meal. All ate a more abundant meal in the evening, and even the noon diner ate a better meal in the evening.

In only one case (13) did the pain set in shortly after eating. This was that of the boy whom I have referred to, who caused himself to vomit. He formed thus an exception to the rule, as stated under No. 2. At the end of the meal the pain would be felt, and, besides, a fulness, a distention in the epigastrium. Expressing a

portion of the ingested matter would at once afford relief. However, the case was rather exceptional in other ways, as will be seen from the history to be related further on.

All were free from pain in the night; slept well, so far as this was concerned, and remained free from suffering till the usual hour the next morning.

4. The means by which relief is obtained: It may be obtained either by neutralizing the acid remaining free in the stomach or by causing it to be taken up by some food matter. Thus, many patients obtain relief by taking a glass of Vichy or a little bicarbonate of sodium in half a glass of water, while others obtain the greatest benefit from a glass of milk or a meat sandwich.

How long the pain would continue if not thus arrested, that is difficult to say, as all patients relieve themselves of their suffering as quickly as possible by one or the other means, and no data are, therefore, at hand to determine this point. It can be assumed with all reason that it would continue until the stomach was altogether emptied. This is the view of the authorities. I, however, believe that the irritation set up in the mucous membrane by the free acid does not subside at once with its discharge from the stomach, but continues on for some time even after that. The tenderness found in the epigastrium would thus be readily accounted for.

Gastralgia.—Paroxysms of gastralgia, more or less severe, are described as part of the symptomatology of this disease. According to Bouveret, they are of frequent occurrence, recurring in most cases after each meal, at about the hours named above for the recurrence of the pain and at about midnight. Riegel says that it is rare for the paroxysms to recur after each meal for any length of time.

The paroxysm does not come on in full force at once; it is of gradual development. At first there is a feeling of uneasiness that is for most persons rather difficult to describe; a light pressure, a feeling of heat, a sense of formication in the stomach; after a while a pain manifests itself which will not yield to the usual remedies, grows more severe, and progresses onward to the gastric spasm in all its severity. The painfulness of this can be at once noted in the appearance of the patient. As Riegel has well said, one need but look at the ghastly countenance to know the intensity of the suffering. Even mild seizures are attended with much pain. At times patients will complain that the greatest suffering is in the back, and will ask somebody to make strong pressure there with their hands or even their feet. After the pain has continued in all its severity for a longer or shorter time, marked eructations—loud and frequently repeated—set in; vomiting of acrid, sour matters, which numb the teeth as they pass over them, follows and the spasm passes. Sometimes the ructus alone is followed by a cessation of the spasm. Pyrosis, with a feeling of heat or burning in the back, may follow in the train of the seizure. The feeling of heat in the back is due to the

passing up into the œsophagus, in the wake of the ructus, of some of the acrid stomach contents, irritating the œsophageal mucous membrane, and with it the terminals of the sensitive nerve filaments distributed there.

Of the twenty-three cases here noted, there was a history of gastralgic seizures in seven. In four of these they had ushered in the gastric disturbance. In one of these cases (1), there was but one attack of most severe type following upon a heavy meal of rather indigestible articles, eaten on a summer afternoon's outing. In the other cases they recurred more frequently. In Case 2 they soon ceased and a "dry pain," as the patient expressed it, took its place; in Case 3 they recurred at longer intervals, while the pain recurred daily.

In the four further cases the seizures were of milder type. In two cases they did not recur with any regularity, the patients going at times a number of days (two to five) entirely free therefrom. In the intervals no pain was felt. In Case 6 they were of irregular recurrence, but in the intervals there would be felt daily a heat, a burning in the stomach that was absolutely painful. In Case 7 the seizures recurred daily, with occasional exacerbations in severity, so that even in the back (from the ninth dorsal to the second or third lumbar vertebra) great pain was felt. In none of the cases was there any complaint made of distress at night.

The data here given bear out fully the statement of Riegel above recorded, that it is rare for the paroxysms to recur after each meal. Furthermore, judging from personal experience, I should say that the earliest, or initiating, paroxysms were usually the severest; that the seizures were apt to be more frequent at the outset of this disturbance of gastric secretion, when the stomach had not, as yet, become accustomed in any way to the irritation and responded thereto with all its force. In a considerable measure, the provoking factor also is responsible for the degree of severity of the paroxysm; thus, it is most severe when provoked by a certain class of foods heavy of digestion and likely to contain irritating matters (such as old cheese and old sausage—particularly blood sausage, etc.) or by excessive indulgence in alcoholic liquors (particularly tart white wines). I have no doubt that it is in cases of such provocation, especially the latter, that the very high percentages of free hydrochloric acid referred to by Bouveret may be found.

II. *Burning in the Stomach.*—In some cases it is not pain that is felt, but a heat, a burning in the stomach which may at times be painful. This may be confined to the epigastrium or may extend to the back in the corresponding region, between the tenth and eleventh dorsal vertebræ. This sensation sets in somewhat earlier in time than does the pain. In most cases it comes on with greater frequency than the pain, occurring also at night and rousing the patient out of his sleep. With this there may occur at longer or shorter intervals gastralgic seizures. Relief therefrom is usually obtained by the same

means that are resorted to to relieve the pain, to wit: a glass of Vichy, some bicarbonate of sodium dissolved in water, a glass of milk, or a glass of milk and lime water. None of the patients so affected who came under my observation ever resorted to more solid matters to allay this distressing feeling.

III. *Sour Stomach*.—In a very few cases the sensation in the stomach does not rise even to the feeling of heat; all that is complained of is a sour stomach, a feeling of acidity in the stomach which is also perceived in the mouth. It seems most readily excited by warm decoctions (such as tea, coffee, or soup) and by tobacco smoking. It is not felt, or but very little, after milk, meat, or eggs.

Of the twenty-three cases recorded, in five the patients complained of the feeling of burning in the stomach. In one of these cases gastralgic paroxysms occurred at longer or shorter intervals, and were usually of a fairly mild character. In two cases out of the twenty-three there was neither pain nor burning; the only complaint was of the sourness of the stomach.

It appeared soon after breakfast when this was a light meal (coffee, tea, oatmeal, bread), and a longer or shorter time after luncheon. It was less manifest (according to the statement made in both cases) after dinner (evening), sometimes being wanting altogether, at other times setting in late in the evening.

It has been said that the thirst is greatly augmented in hyperacidity. Riegel states that he has not found it to be so, except at the time when the irritative manifestations in the stomach supervened. Of my twenty-three cases, no thirst was complained of, or undue quantity of drink taken, in twenty-two. It was just the reverse in many of the cases; it was with difficulty that I could persuade the patients (the constipated ones) to drink sufficiently of cold water.* Only one patient (the twenty-third), a young girl aged seventeen, working in a sewing establishment, drank a large amount of water through the day, and here it was done to assuage the irritation, the pain in the stomach (she knew of no other means and had no other means at hand), and as that was soon relieved by a proper diet, the inordinate drinking ceased with it.

Ructus (Eructation).—In all forms of functional stomach troubles eructations are a prominent and, to the patient, very annoying symptom. They are often loud and frequently repeated, recurring for from two to three hours after the meal. In hyperchlorhydria, except upon the termination of a gastralgic paroxysm, as already described, eructations either are altogether wanting or in no way differ from those occurring in the normal state. I have questioned my patients very particularly and very fully as to this, and all affirmed that they were not troubled in this way. Why this should be so can be

readily understood. I lay some stress upon this point as of considerable diagnostic value.

The Bowels.—Constipation is of frequent coincidence with hyperacidity. Of my twenty-three patients, seven were regular and sixteen were constipated. Excluding one patient, an old lady in whom the constipation was undoubtedly due to a markedly hæmorrhoidal condition of the lower segment of the rectum, there remain fifteen, or nearly two thirds, in whom some connection between the two conditions may be presumed. The constipation is not necessarily, however, as has been maintained by some authors, of a particularly obstinate character. In fact, there is nothing peculiar or characteristic about it; it is of all degrees, just as it is found otherwise. Excluding from the fifteen patients four, who were seen but a very few times and at irregular intervals, there remain eleven who were under continuous observation and treatment. Of these, four had constipation of a very mild type, which yielded readily and quickly to appropriate treatment (massage, diet, etc.); six required a more prolonged treatment, but not any more so than is frequently found necessary in cases not connected with hyperchlorhydria; one only, the boy of twelve already referred to, proved refractory, and it took a very long time and very assiduous work before a proper activity of his intestinal canal was secured. But there is nothing extraordinary even about this case; I have had some few other cases of constipation, without hyperchlorhydria, that were as refractory and were under treatment for even a longer period.

As to the relationship between constipation and hyperacidity, it is said by some that the former is but a symptom of the latter. I do not so hold; as I shall endeavor to show further on, their relationship is in the greater number of cases of a different nature, while in the few they are both the effect of one and the same cause.

Riegel says that not infrequently the constipation alternates with diarrhœa. I have seen something similar in but two of my cases, including that of the young girl who drank so much water, and who had a cycle like this: Constipation for a few days, then diarrhœa for some days, then regularity for some days. In the other case the patient had diarrhœa most of the time through the hot months, and was always constipated during the cooler season.

(To be continued.)

The Suffolk County Medical Society held its annual meeting at Riverhead, L. I., on April 25th. Dr. J. H. Benjamin, of Riverhead, presided, and Dr. F. A. Overton, of Patchogue, recorded. The following officers were elected: President, Dr. John H. Benjamin, Riverhead; vice-president, Dr. A. C. Loper; secretary, Dr. P. V. B. Fowler; treasurer, Dr. B. D. Skinner; librarian, Dr. J. H. Benjamin; censors, Dr. Terry, Dr. Wells, and Dr. Raynor. As delegates to the State Medical Society's meeting, Dr. P. V. B. Fowler, Dr. W. B. Savage, Dr. A. M. Payne, Dr. W. H. Ross, and Dr. B. F. Manny were elected.

*For the reason therefor, see Illoway, *Constipation in Adults and Children, with Special Reference to Habitual Constipation*, etc.

A CASE OF SARCOMA IN THE
MUSCLES OF THE RIGHT SHOULDER,
WITH
PERFORATION INTO THE SPINAL CANAL
AND PARAPLEGIA.*

BY LEONARD WEBER, M. D.,
NEW YORK.

FRANK B. presented himself first at my office in June, 1893. He was a comely-looking, intelligent man, twenty-two years old, of medium height, well built, who had learned the trade of printing and worked at it steadily during the last three years; both his parents died of acute diseases. A sister, two years older than himself, had chronic Bright's disease, probably of scarlatinal origin, which was manageable for a number of years, but she finally died rather suddenly during convulsions, in 1895; another sister, five years older than Frank, is living and in good health. At the time of his calling the patient had the usual symptoms of syphilis, which had constitutionally manifested itself three months before and so far been indifferently treated; for the following three months he received careful and energetic treatment by mercurial inunctions, combined with small doses of iodide of potassium. He progressed favorably, and, when examined again, on October 1st, appeared to be entirely free of all lesions of the skin and mucous membranes. Though looking somewhat pale at that time, he was able to be about and attend to his work; but in November a slight relapse occurred in the form of mucous patches and various characteristic erythematous spots upon the integuments, which, however, yielded rapidly to mercurial vapor baths and small doses of the iodides. By December 12th he was again free of all symptoms and ordered to take of the elixir of calisaya bark and iron the usual doses three times a day, for tonic purposes.

In 1894, on January 25th, he presented himself again and showed a circumscribed tender swelling of the cartilaginous part of the nasal septum—specific perichondritis—and a small, roundish, somewhat tender, movable tumor of about the size of a cherry, seated well beneath the superficial fascia in the fleshy part of the right shoulder, between the scapula and the spine and at about the level of the crista scapulae. To consider both lesions as rather early tertiary manifestations of syphilis seemed reasonable, and he was put on "mixed treatment" in the form of:

℞ Mercury biniodide. 2 grains;
Potassium iodide. 2 drachms;
Wine of pepsin. 8 ounces.

M. S. Two teaspoonfuls three times a day.

This was continued until February 22d, when the nasal ulcer was entirely healed and all tenderness had gone from the supposed gummatous growth in his shoulder, though the small, hard nodule remained and probably never entirely disappeared. He continued the above-mentioned medicine *refracta dosi* until March 27th, when he came again with a supraorbital tophus on the left side, which made an increase of the usual doses of medicine desirable; this was done and he continued to take it until April 17th, when all the manifestations had healed again.

During the month of November of that year he was troubled with seborrhœa capitis and falling out of the

*Read before the New York Neurological Society, April 2, 1901.

hair and considerable rather diffused headache, all of which again yielded to the "mixed treatment."

In 1895, in February, he appeared to be in good health and spirits, but the previously noted small nodule in the shoulder region could still be felt, though it was not tender. In October of the same year the patient had his first attack of gonorrhœa, of which he recovered completely within two months and without sequelæ.

In 1896, on September 10th and again on December 6th, I had occasion to prescribe for him in the office for trifling ailments not connected with any relapse of the old disease; the small tumefaction in the shoulder, however, could always be felt, although it did not trouble the man in any way—in fact, he would never mention it. During the next three years I saw nothing of him, but was informed by his sister early in 1900 that her brother had become demoralized, had thrown up his job, and for the last three years had led a dissolute life and been frequently grossly intoxicated.

On June 15, 1900, he appeared again at my office to obtain relief from a pain in the right shoulder caused by a swelling which had started, he said, after a blow he had received from a man with whom he had had words while he was taking a drink about a year before. In the shoulder region previously spoken of a hard, solid, immovable tumor of the size of a goose's egg could be made out. The integuments were not attached to this growth or changed in color, and it was not very tender. It interfered somewhat with forward and backward movements of the arm, but there were no enlarged lymphatics in the armpit or in the neck. Thinking and hoping that it might be a gumma, I put the patient on the use of rapidly increasing doses of the iodide of potassium combined with mild tonics on account of his generally run-down condition. Though some general improvement followed, the tumor became rather larger and more painful at the end of July, so that I thought best to change the prescription for one of iodide and mercury. This was ordered and continued from August 10th to September 10th, when deep-seated, elastic fluctuation could be distinctly made out in the tumor. I drew out about a drachm of gummy, thick, bloody liquid, which, in conjunction with small pieces of the tumor later cut out, were submitted to the pathologist, who pronounced it round-celled sarcoma. Upon this report, all specific treatment was stopped and the patient prepared for an operation, which was attempted at the hospital on September 24, 1900, but the surgeon found it impossible to do more than remove the débris of the tumor mass and various necrotic pieces of bone, and he then packed the copiously bleeding cavity with iodoform gauze. In the progress of the operation we could readily make out that both spine and scapula were already invaded by the malignant growth. There was no particular reaction after this procedure; the patient was soon out of the hospital and came to my office to receive hypodermic injections of:

℞ Arsenate of sodium. 1 part;
Carbolic acid. 2 parts;
Distilled water. 100 "
M.

From fifteen gradually up to thirty minims every third day were given, with the slight hope of preventing the case from going from bad to worse. By the end of November the tumor, not much larger than before, became quite tender and bled pretty profusely from the operation wound as often as the dressings were changed.

On December 11th his sister called and reported that her brother was beginning to lose the use of his limbs. I had him at once admitted into St. Mark's Hospital, and on the 14th paraplegia was complete, with vesical and rectal paralysis and intestinal meteorism. For some days thereafter pain on pressure could be felt in the lower extremities, but the sensory perceptions became weaker as time went on. Though the patient's hands and arms were also weak, paralysis did not develop in them; in spite of all possible care, bed-sores occurred in the course of time and the patient became emaciated and septic. That the tumor had invaded the spinal canal seemed probable, though it was more reasonable to suppose that hæmorrhage had taken place into the spinal canal, compressing the cord, on account of the rather sudden development of the paraplegic symptoms.

On February 11, 1901, in the morning, the patient died from exhaustion. I was permitted to make a local autopsy only, which was done late in the afternoon of that day, and the tumor, with a portion of the spinal cord, was removed. The large central and sloughing crater of the tumor, which I pass around, led to a small opening between the vertebral processes into and through the dura mater to the spinal canal; between the two upper dorsal and the two lower cervical vertebræ the cord was covered by an old extravasation about two inches in length, which at the time of the post-mortem was about two millimetres in thickness in the central parts and reddish in color and thinned off above and below.

Though it is possible that this sarcoma started from the periosteum and bone of vertebræ or scapula, I am not of the opinion that it did so start, provided the original nodule, which, as you remember, was still present in 1897, commenced growing after his receiving a blow in 1899. That small growth was in the flesh midway between scapula and spine, and, I am quite sure, was not attached to either of them. But we must also take into consideration that the supposed gumma may have disappeared entirely during the three years that I had lost sight of the patient; then, indeed, it may be that this tumor is a malignant new growth not at all connected with the previously noted lesion. At the time of the operation it was altogether too late for a radical procedure, but it might have been better perhaps to make use of the cautery for the purpose of enucleating the tumor mass and removing all that could be removed.

In asking your indulgence for a few epicritical remarks on this case, I should like to say that we have here a case of malignant growth developing in a comparatively young subject about a year after a probably not severe trauma in the region of the body where it was believed that there had been, a few years previously to that trauma, a specific lesion—a gumma—which had grown in the fleshy parts. To be sure, a gumma cannot change into sarcoma, but we do know that after chronic as well as acute injuries of apparently healthy or already somewhat diseased parts cellular proliferation and new growths may be started. This has been observed not only in the various orifices of the human body, but also in bony and muscular tissues and in the viscera. We further see here that, though there were sufficient time and room for the sarcomatous growth to invade the spinal

cord or leptomeninges, such invasion did not take place, and the cord symptoms in this case were due to hæmorrhage and degenerative myelitis, as a microscopical examination of the cord has shown. As to the question of whether the little tumor first felt in the shoulder of the patient five years ago was malignant, we do not infrequently see sarcoma and epithelioma remain in the early stage for a comparatively long while; it would no doubt have been an easy task to remove the small growth at any time prior to 1897, and this peculiar case should teach the lesson that it is wise to excise a supposed gummatous tumor located in accessible regions when it does not yield to proper specific treatment in due time.

25 WEST FORTY-SIXTH STREET.

Therapeutical Notes.

A Mixture for Neurasthenia.—Flesch (*Wiener klinische Rundschau*, 1900, No. 43; *Deutsche Aerzte-Zeitung*, May 1st) recommends the following formula:

℞ Iron and quinine citrate. 38 grains;
Strychnine nitrate. 1½ grain;
Fluid extract of kola, } each, 6 drachms;
Sodium glycerophosphate, }
Syrup of orange. 6 ounces.

Dissolve the other ingredients in the syrup of orange with the aid of a gentle heat.

S. A coffeespoonful three times a day, after meals.

For Syphilis.—*Progrès médical* for May 4th ascribes the following to Debove and Gourin:

℞ Mercury soziodolate. 12 grains;
Potassium iodide. 24 “
Distilled water. 150 minims.

M.

One hypodermic injection daily (one cubic centimetre, about 15 drops, equals 1½ grains of the mercury salt).

Galezowski's Ointment for Neuralgia, according to Bocquillon-Limousin (*Formulaire des médicaments nouveaux*), is made as follows:

℞ Menthol. 23 grains;
Cocaine. 7½ “
Chloral hydrate. 5 “
Vaseline. 2½ drachms.

M.

Huchard's Diuretic and Cardiac Tonic.—Bocquillon-Limousin (*Formulaire des médicaments nouveaux*) gives the following formula of a mixture employed by Huchard in cases of nephritis with cardiac weakness:

℞ Tincture of grindelia. 30 parts;
Tincture of convallaria. 10 “
Tincture of squill. 5 “

M.

Dose, fifteen drops, three times a day.

Caffeine in the Treatment of Whooping-cough.—The *Agenda-médical* for 1901 gives the following formula:

℞ Caffeine valerianate. 3 parts;
Brandy. 40 “
Syrup of coffee. 500 “

M.

From a coffeespoonful to a tablespoonful, according to the patient's age, is to be given morning and evening.

62-68 West Broadway.

NEW YORK, SATURDAY, JUNE 1, 1901.

VENEREAL DISEASE IN NEW YORK.

TOWARD the close of February the Medical Society of the County of New York passed a resolution empowering its president to appoint a committee "for the study of the most practical kind of municipal or State legislation to repress or control prostitution, with a view of reducing the morbidity and mortality from venereal diseases." The committee appointed under this resolution consists of Dr. Prince A. Morrow (chairman), Dr. Ludwig Weiss (secretary), Dr. George B. Fowler (*ex-officio* member as president of the society), Dr. Charles W. Allen, Dr. L. Duncan Bulkley, Dr. Henry Dwight Chapin, Dr. Edward D. Fisher, and Dr. S. Adolph Knopf. A committee composed of such men as these is eminently fitted to collate exact information regarding the degree to which venereal diseases are at present rife in New York, the channels through which they are chiefly spread, their effects in more or less permanently crippling such of their victims as they do not in the end really kill, and in short everything capable of enabling legislative bodies to grasp the subject in all its hideous portent to the community. Such information, coming authoritatively from the practising physicians and the hospitals, dispensaries, and clinics of the town, stated so intelligibly as the committee may be trusted to state it, with analyses and deductions, is the essential primary step in the task of giving the legislator a clear comprehension of the magnitude and gravity of the problem which the committee has set itself to work to study. For the purpose of collecting as great a mass of facts as possible, the committee has sent a circular of inquiry to every physician in the city and is making a personal canvass of the various institutions in which venereal diseases are treated.

In the committee's circular the physician is asked to state the number of cases of venereal disease that oc-

curred in his private practice during the past year, specifying the number of cases of gonorrhœa and the number of cases of syphilis. In regard to gonorrhœa, the committee is striving to obtain as full returns as practicable concerning the following points: The number of cases occurring respectively in men, in women, and in children, the number of cases leading to pelvic sequelæ in women, and the number of cases of gonorrhœal ophthalmia and of vulvovaginal inflammation in children. Concerning syphilis, it asks for the number of cases occurring in men, in women, and in children respectively, and, in the matter of syphilitic children, the ratio of the acquired to the hereditary cases. The circular also calls for reports as to the origin of the infection, whether from public prostitutes, from clandestine prostitutes, in marital relations, by heredity, by extragenital access, or from an unknown source. The fullest possible information is asked for as to the prevalence of syphilis inson-tium, gonorrhœal infection in married life, and venereal diseases occurring in children. Finally, these general questions are asked: "Judging from the results of your observation, are venereal diseases on the increase in this city?" and "What measures, in your opinion, are best adapted to limit or prevent the dissemination of venereal diseases in this city?"

Though it would be easy to mention some other points concerning which the committee might legitimately ask for data, it will be seen that those which they have chosen are of great practical significance and probably in themselves sufficient to procure an array of facts quite adequate as a foundation for a picture that will prove startling to the community. We are glad to know that the committee's inquiries are eliciting prompt responses in great numbers; we learn that within the ten days following the issue of the circular 800 replies were received. There ought to be no exceptions; every physician to whom the inquiry is addressed ought to send his answer at once, and make it full and explicit, and he ought also, and above all, to respond to the two final questions only after careful thought.

TROPICAL DISEASES AS OBSERVED IN THE
PHILIPPINES.

IT was not to be supposed that the Army Medical Corps could long include the Philippine Islands within its field of work without giving to the world some valuable data concerning the diseases observed in those islands. We are not surprised, therefore, to receive the first number of *Circulars on Tropical Diseases*. The

series is issued under the authority of Surgeon-General Sternberg by Colonel Charles R. Greenleaf, assistant surgeon-general and chief surgeon of the Division of the Philippines. The first number, dated February 4th, presents the results of investigations by First Lieutenant Richard P. Strong, assistant surgeon, in charge of the Army Pathological Laboratory, Manila, and president of the Board for the Investigation of Tropical Diseases in the Philippines. Before commenting upon the substance of the circular, which consists of forty-five octavo pages, we wish to say that, in view of the necessarily limited present facilities for printing in the English language in the Philippines, its typographical appearance is exceedingly creditable. The italic *u* does duty for the Greek μ , but, when we call to mind the frequency with which, in communities far longer accustomed to our language, the inverted numeral 5 is made to take the place of the French ζ , we may well look upon the substitution as the best that could have been resorted to in the absence of Greek type. There are but few errors of proof-reading, and the general appearance of the pamphlet will compare favorably with that of medical publications in general.

In this first issue Dr. Strong deals entirely with the animal parasites and the diseases caused by them, giving rudimentary zoological data, brief notes of the prevalence of the parasites in the Philippines, and, in a few instances, hints on the diagnosis and treatment of the diseases to which they give rise. Of the *Protozoa*, he treats of the *Amæba dysenteria*, of very common occurrence in the islands, and of the *Amæba coli*, which apparently is not pathogenic and is not often encountered. But one *Infusorium*, the *Balantidium (Paramecium) coli*, has been met with. When present in large numbers, this parasite may give rise to severe chronic diarrhœa, although it has generally been regarded as almost harmless. Three *Mastigophora (Flagellata)* have been observed. The first resembles the *Trichomonas vaginalis* of Donnè, the second is apparently the *Cercomonas hominis* of Davaine, and the third appears to be identical with the *Megastoma entericum* of Grassi, except that on the posterior lip of the excavation only two flagella have been observed instead of four. It is thought to be not unlikely that these flagellates may, when present in large numbers, "cause some intestinal irritation, perhaps by their mechanical movements." Of the cestodes, only two adult forms have been encountered, *Tænia medio-canellata* and *Tænia solium*. The *Cysticercus cellulosa* has not been observed in man, but is frequently found in

pigs. Two cases of echinococcus cyst have been met with, both discovered post mortem. The *Ascaris lumbricoides* is the commonest of the nematodes in the Philippines; the *Oxyuris vermicularis* has been observed in several instances; the *Trichocephalus dispar* is very common; the *Trichina spiralis* has not been found in man, though it has been in Manila hogs; infection with the *Filaria nocturna* has occurred in one instance; ankylostomiasis has been recorded a number of times, including eight fatal cases, but the author thinks that it was not the sole cause of death in any of them; and thirteen examples of infection with the *Strongyloides intestinalis* have come under his observation. Seven cases of myiasis interna have been observed. The larvæ were generally those of *Calliphora vomitoria*, more rarely those of *Anthomyia canicularis*. The symptoms were moderate diarrhœa and occasionally gastric or intestinal pains. Little leeches, not more than two thirds of an inch long, have at times troubled the soldiers considerably on the march, particularly along the bases of mountains in wooded districts. They seem to cling to the branches of trees or to lurk in the grass, and to fasten on persons as they pass. They commonly attack the ankles, seeming to have gained access at the shoe-laces. "In several cases they have entered the eye and fastened themselves beneath the lid, causing considerable pain and anxiety." It is not known that the *Paragonimus Westermanii* has yet been found in the Philippines.

Dr. Strong must be credited with having produced a report which, while adding not a little to our general stock of knowledge, will prove of special aid to the inexperienced medical officer during his novitiate in the Philippines. We do not doubt that the succeeding circulars of the series will be equally helpful.

THE GOOD WORK OF THE BROOKLYN MEDICAL CLUB.

IN this issue we present an important contribution toward the elucidation of one of the fundamental problems of medicine, that of inherited physical peculiarities and morbid states. We are alluding to Dr. Adami's address, which was delivered under the auspices of the Brooklyn Medical Club. It is the first of a series of annual addresses provided for by the club. Its quality, such as is always to be expected from the distinguished pathologist of Montreal, shows the lofty ideal of the club in arranging for these addresses. There are problems in medicine that are hardly to be solved by laboratory

research or clinical observation alone, although those sources of knowledge are in almost every instance contributory to the final solution. The finishing touch has to be given, not by the laboratory man or by the clinician, but by him who, being perhaps neither an original investigator nor a physician in active practice, although, as in this instance, he may be both, brings to the ultimate summing up the qualities of the analyst and those of the logician, those of a well-ordered thinker. It is the voice of such a man that is apt to be heard on occasions long and carefully prepared for rather than in casual debate or in experimental contributions. Such occasions are those of the formal lectures provided for by endowment funds, of which there are several examples in this country and in Great Britain. By adding one more to these opportunities for advanced instruction the Brooklyn Medical Club has done a distinct benefit to medicine.

The subjects to be dealt with by the Brooklyn lecturers, we understand, are of such a nature that, while they may not have a direct, everyday bearing upon the bedside medicine of the present time, they bear an intimate relationship to the principles that are yet to be evolved as the bases of the medicine which is to be developed in the future. The men who prepare such lectures are apt to be something even more than shrewd analysts and clever interpreters; they are often to a considerable extent pioneers in certain lines of thought, and the more suggestive they prove, within the limits of reasonable speculation, the more likely are they to rouse others to focus their mental vision on the points that chiefly lack precise recognition. No one man often wields alone the implement that hammers out a great principle in science; repeated blows from various quarters are generally required to beat the mass of facts into coordination and manifest unity of purport. To bring forward the men to strike these blows is to render an essential service to progress, and upon that beneficent undertaking the Brooklyn Medical Club has entered. Its efforts should and doubtless will be appreciated by the entire medical profession, and unstinted encouragement be given to it.

WOMEN PHYSICIANS IN ANCIENT GREECE.

It may not be generally known that there is evidence of the existence of lady doctors in ancient Greece. Marcel Baudouin publishes in the *Gazette médicale de Paris* for February 23d a note on this subject in which he reproduces and comments on three monumental inscriptions. The first states that "Gaius Julius Vettianus in

his lifetime has raised this monument to himself and to his wife Empiria, the physician (*ειατρεινη*), who lived to the age of forty-nine years." This inscription would seem, from internal evidence, to be before the Christian Era. The two others read respectively, "The Sarcophagus of Basilla, the (female) physician (*ιατρινης*); (*ειατρινης*)." These apparently refer to Christians, for both, after the early Christian fashion, are preceded and followed by a cross, and the first, moreover, is said to have been found in the Christian cemetery at Corycos, in Cilicia.

AN EXTRAORDINARY LEGAL DECISION.

IN the Southwark County Court, London, the judge has recently given a decision, according to the *Medical Press and Circular* for May 8th, which strikes us as being extraordinary, to say the least of it. It would appear that a practitioner who was attending a child, finding that the mother would not carry out his instructions, retired from the case. He sent in a claim for fees due on account of "work done," which claim was contested in court, and the judge decided against the plaintiff on the ground that, "having thrown up the case, which he was entitled to do, he could not charge for his services." The logical outcome of this decision is that a physician is at the mercy of any obstreperous patient who chooses to confront him with the alternative of either foregoing his fees or submitting to the indignity of having his instructions set at naught, thus not only wounding the physician's sense of responsibility, but probably seriously affecting his professional reputation.

FRAME HOUSES.

AN editorial comment in the *Polyclinic* for April, in A Plea for Wooden Houses, makes what appears to us to be a somewhat curious statement. Referring to the prohibition in England of wooden houses, even in country districts, the writer, while acknowledging the unsuitableness of wood, on account of its inflammability, as a material for the construction of "houses that stand in streets or near to those in the possession of other owners," says: "A cottage of wood is far drier, is warmer in winter and cooler in summer than one of stone or brick"! And, again: "It is the rarest possible event to see anything of the nature of either mould or rust, and no trace of damp on the wallpapers is ever observed"! Whatever other merits frame houses may have—and, according to our author, they are "not much cheaper to build than brick" in England—we think that few in this country would assent to the two propositions first stated, except as regards log-houses. But possibly they build even wooden houses more substantially across the water than in this part of the world.

News Items.

Society Meetings for the Coming Week:

MONDAY, June 3d: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, June 4th: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, June 5th: New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y., (New Brighton); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, June 6th: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, June 7th: Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, June 8th: Obstetrical Society of Boston (private).

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending May 24, 1901:

Small-pox—United States and Insular.

Hoonah, Alaska.....	May 11.....	15 deaths.
Killisnoo, Alaska.....	May 11.....	4 cases.
Los Angeles, California.....	Apr. 27-May 11..	12 cases.
San Francisco, California.....	May 4-11.....	6 cases.
Chicago, Illinois.....	May 11-18.....	6 cases.
Coalgate, Indian Territory...	May 11.....	65 cases.
Wichita, Kansas.....	May 4-18.....	37 cases.
Lexington, Kentucky.....	May 11-18.....	4 cases.
Baton Rouge, Louisiana.....	May 5-12.....	2 cases. 1 death.
New Orleans, Louisiana.....	May 11-18.....	9 cases. 2 deaths.
Boston, Massachusetts.....	May 11-18.....	10 cases.
New Bedford, Massachusetts.....	May 16-18.....	5 cases.
Detroit, Michigan.....	May 11-18.....	58 cases.
Minneapolis, Minnesota.....	May 4-11.....	23 cases.
Nebraska City, Nebraska.....	Mar. 30.....	5 cases.
South Omaha, Nebraska.....	Apr. 23-May 21..	36 cases.
Manchester, New Hampshire...	May 11-18.....	4 cases.
Jersey City, New Jersey.....	May 5-19.....	15 cases.
Newark, New Jersey.....	May 11-18.....	4 cases. 1 death.
New York, New York.....	May 11-18.....	105 cases. 13 deaths.
Cincinnati, Ohio.....	May 10-17.....	9 cases. 1 death.
Cleveland, Ohio.....	May 11-18.....	54 cases.
Youngstown, Ohio.....	May 4-18.....	2 cases.
Lebanon, Pennsylvania.....	May 11-18.....	4 cases.
Philadelphia, Pennsylvania.....	May 11-18.....	3 cases. 1 death.
Pittsburgh, Pennsylvania.....	May 11-18.....	2 cases.
Steelton, Pennsylvania.....	May 11-18.....	2 cases.
Williamsport, Pennsylvania...	May 11-18.....	1 case.
Memphis, Tennessee.....	May 11-18.....	12 cases.
Nashville, Tennessee.....	May 11-18.....	3 cases.
Salt Lake City, Utah.....	May 4-11.....	7 cases.
Tacoma, Washington.....	May 1.....	1 case from Wash-on Island.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending May 25, 1901:

- DE LANCY, C. H., Assistant Surgeon. Detached from the *Bancroft* and ordered to the *Buffalo*.
 FURLONG, F. M., Assistant Surgeon. Detached from the *Brutus* and ordered to proceed to Guam, L. I.
 GROW, E. J., Assistant Surgeon. Detached from the *Isla de Luzon* and ordered to the *Castine*.
 PLUMMER, R. W., Assistant Surgeon. Detached from the *Petrel* and ordered to the *Nashville*.
 STEPP, J., Assistant Surgeon. Detached from the *Castine* and ordered to the *Isla de Luzon*.
 STONE, M. V., Assistant Surgeon. Detached from the *Buffalo* and ordered home to await orders.
 THOMPSON, E., Assistant Surgeon. Detached from the *Solace* and ordered to the *Petrel*.

The following assistant surgeons are ordered home via public conveyance: BEEBE, D. G.; FURLONG, F. M.; GROW, E. J.; GRUNWELL, A. G.; KERR, D. B.; LANGHORNE, C. D.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from May 18 to 25, 1901:

- BACHE, DALLAS, Colonel and Assistant Surgeon-General. The sick leave granted him is extended three months.
 BRECHEMIN, LOUIS, Major and Surgeon. So much of Par. 23, S. O., 118, May 21, 1901, as directs him to proceed to Fort Bayard, New Mexico, for temporary duty in charge of the United States General Hospital at that place, is revoked.
 GANDY, CHARLES M., Captain and Assistant Surgeon. So much of Par. 14, S. O., 40, February 16, 1901, as relates to him is so amended as to direct him upon his relief from duty at Fort Slocum, N. Y., to proceed on the transport *Ingalls* via the Suez Canal to Manila, and report in person to the commanding general, Division of the Philippines, for duty.
 METZGER, JOHN A., Major and Surgeon. The leave of absence granted him is extended one month.
 SINKS, EDWARD D., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.
 SWIFT, EUGENE L., Captain and Assistant Surgeon, will report in person to Lieutenant-Colonel CALVIN DE WITT, president of the examining board convened at the Army Medical Museum Building, for examination as to his fitness for promotion.

WASHBURN, FREDERICK A., JR., Major and Surgeon, will proceed to San Francisco for transportation to Manila.
WINTER, FRANCIS A., Captain and Assistant Surgeon, will proceed to Fort Sheridan, Illinois, for duty.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending May 23, 1901:

CLARK, TALIAFERRO, Assistant Surgeon. Granted leave of absence for thirty days from May 22d.
CORPUT, G. M., Assistant Surgeon. To proceed to the South Atlantic Quarantine Station. Granted leave of absence for one month.
DECKER, C. E., Assistant Surgeon. Granted leave of absence for ten days from May 11th, on account of sickness.
GLENNAN, A. H., Surgeon. To rejoin station at Habana.
GREENE, J. B., Passed Assistant Surgeon. Granted five days' extension of leave of absence.
PECKHAM, C. T., Surgeon. Granted leave of absence for thirty days from April 19th, on account of sickness. Granted thirty days' extension of leave of absence, on account of sickness from May 20th.
RODMAN, J. C., Acting Assistant Surgeon. Granted leave of absence for four days.
SLAUGHTER, A. W., Acting Assistant Surgeon. Granted leave of absence for four days from June 4th.
WERTENBAKER, C. P., Passed Assistant Surgeon. To proceed to Meridian, Mississippi, for special temporary duty.

BOARD CONVENED.

Board convened to meet at Washington May 20, 1901, for the purpose of making physical examinations of applicants for cadetship in the Revenue Cutter Service. Detail for the Board: SURGEON L. L. WILLIAMS, Chairman; ASSISTANT SURGEON B. S. WARREN, Recorder.

Scarlet Fever.—The prevalence of this disease at Whitestone Landing, L. I., is occasioning some alarm.

Dr. L. Emmet Holt has been appointed clinical professor of diseases of children at the College of Physicians and Surgeons.

Dr. A. L. Gray has been elected to succeed Dr. MacLean as professor of physiology in the University College of Medicine, Richmond, Va.

The New Buildings of the Mount Sinai Hospital were formally begun by the ceremonial laying of the cornerstone on May 22d.

In Memory of Dr. Thomas F. Rumbold.—A special meeting of the St. Louis Medical Society was held recently for the purpose of adopting resolutions of regret at the death of the late Dr. Thomas F. Rumbold.

In Memory of Dr. F. J. Brockway.—A formal minute of sorrow for the death of Dr. F. J. Brockway, former president of the West End Medical Society of this city, and of esteem for his many excellent qualities, was recently adopted by the association of which he was formerly the president.

The Northwestern University Medical School, Chicago, has again enlarged the requirements by the addition of another year. The object of the fifth year is to furnish to students not receiving hospital internships a more practical course than is compatible with the diverse routine work of the third and fourth years. The service will be made as nearly equivalent to a hospital internship as possible.

A World's Congress of Tuberculosis is to be held in London in August. Dr. George Brown, of Atlanta, Ga., has been elected by the American Congress of Tuberculosis, at its recent meeting in New York, to represent it at the London congress.

Anthrax at Batavia, N. Y.—A special dispatch to the *Rochester Herald* states that a valuable herd of Jersey cattle has been found by a veterinary surgeon to be afflicted with anthrax, seven animals out of thirty having died within a week. An investigation is being made by the health officer.

The American Academy of Medicine, which will hold its twenty-sixth annual meeting in St. Paul, beginning June 1st, was organized in Philadelphia during the centennial of 1876. It was formed to be a distinctively American society of physicians whose college and university training should be fairly equivalent to that required in Europe. The officers of the academy are: President, Dr. S. D. Risley, of Philadelphia; vice-presidents, Dr. C. M. Culver, of Albany; Dr. Rosa Englemann, of Chicago; Dr. G. G. Groff, of Lewisburg, Pa., and Dr. C. T. McClintock, of Detroit; secretary and treasurer, Dr. Charles McIntire, of Easton, Pa.; assistant secretary, Dr. A. R. Craig, of Columbia, Pa.

New York City Hospitals Inadequately Supported.—According to a writer in the *New York Evening Post*, recent inquiry at the offices of four of the largest hospitals in New York—namely, St. Luke's Episcopal, on Cathedral Heights; the Presbyterian, in Madison Avenue; the German, at Park and Lexington Avenues, and the Roosevelt, at Ninth Avenue and Fifty-eighth Street—brought out the fact that every one of them was struggling under a deficit, representing the difference between the institution's income and its expenditures for the year. In this respect the Presbyterian is perhaps the worst off, the treasurer reporting that, during last year, current expenses exceeded receipts by \$77,364.32. Next comes St. Luke's, with a balance of \$62,043 on the wrong side, while the German and the Roosevelt are comrades in poverty to the extent of about \$11,000 during the last year.

Small-pox.—Health Officer Doty is being kept busy inspecting the steamships from Southern Europe, especially Italy, almost every one of which brings with it steerage passengers suffering from small-pox. The disease is still cropping up in New York and Brooklyn, and the list on May 21st was fifty-six new cases within two days.—Sporadic cases are being reported in Dutchess county, N. Y.; at Gloucester City, N. J.; Chester, Pa., and at Fitchburg and Leominster, Mass.—Some interesting figures have recently been given out by Assistant Sanitary Superintendent Dillingham, of the New York City Health Department. They show that small-pox is prevalent all over the United States. The period of his figures extends from December 28, 1900, to May 3, 1901. New York has had in that period 723 cases out of a total in all the States and Territories of 22,344. Some of the States which lead are Kansas, 3,915; Colorado, 1,763; Minnesota, 2,753; North Carolina, 723; Ohio, 1,685; Tennessee, 4,228, and Utah, 724. The other States and Territories showed the following numbers of cases in the same period: Alabama, 45; California, 64; Connecticut, 9; Delaware, 57; Iowa, 26; District of Columbia, 51; Florida, 113; Georgia, 22; Idaho,

10; Illinois, 354; Indiana, 557; Indian Territory, 216; Kentucky, 59; Louisiana, 206; Maine, 1; Maryland, 26; Massachusetts, 15; Michigan, 55; Minnesota, 2,753; Mississippi, 4; Missouri, 215; Montana, 218; Nebraska, 654; Nevada, 1; New Jersey, 46; New Hampshire, 334; New Mexico, 4; North Dakota, 66; Oklahoma, 690; Oregon, 10; Pennsylvania, 221; Rhode Island, 10; South Carolina, 10; Texas, 486; Virginia, 328; Washington, 38; West Virginia, 66; Wisconsin, 575, and Wyoming, 4.

The Academy of Medicine of Chicago has elected the following directors for the coming year: Dr. W. L. Baum, Dr. J. G. Kiernan, Dr. C. S. Hallberg, Dr. H. N. Moyer, Dr. E. S. Talbot.

The Rhode Island Medical Society will hold its ninetieth annual meeting in the Masonic Building at the corner of Dorrance and Pine Streets, Providence, at 10 A. M., on Thursday, June 6th, the annual dinner taking place at 1 o'clock in the Trocadero.

The American Medico-psychological Association, formerly known as the Association of Medical Superintendents of American Institutions for the Insane, will hold a four days' session at Milwaukee, Wis., beginning on June 11th, at the Hotel Pfister. Dr. Peter M. Wise, of New York, is the president, and Dr. C. B. Burr, of Flint, Mich., is the secretary and treasurer. An interesting programme of papers to be read has been issued.

The New York Academy of Medicine will hold a stated meeting on Thursday evening, June 6th, at 8.15 P. M. The order of business includes the presentation of the portrait of Dr. William H. Thomson, formerly president of the New York Academy of Medicine, by Dr. W. H. Polk; a paper on The Freezing-point of Urine, its Determination and the Inferences which may be Drawn from it, by Dr. J. H. Huddleston; and one on The Early Recognition and Management of Arterial Degeneration, by Dr. Louis F. Bishop.

The German Medical Society of the City of New York will hold its next meeting in the Academy of Medicine on Monday evening, June 3d. Among the specimens shown will be blood preparations from a case of splenomyelogenous leucæmia complicated with tuberculous disease of the larynx and lungs. Papers will be read as follows: Chronic Fluorine Poisoning, by Dr. Fritz Schwyzer; The Limitations of Orthopædics, with a Demonstration of Orthopædic Apparatus, by Dr. Charles H. Jaeger; and Nasal Affections in Typhoid Fever, by Dr. M. Toepflich.

The Massachusetts Medical Society.—The one hundred and twentieth annual meeting will be held in Boston on Tuesday and Wednesday, June 11th and 12th, under the presidency of Dr. Frank W. Draper, of Boston. The section meetings will be held in the Medical Library on Tuesday. The programme for the Section in Medicine, under the chairmanship of Dr. William W. Eaton, of Danvers, includes the following papers: General Considerations of the Nutrition of Infants, by Dr. T. M. Rotch, of Boston; Infantile Atrophy, by Dr. J. L. Morse, of Boston; Infantile Scurvy, by Dr. E. L. Peirson, of Salem; Rhachitis, by Dr. A. R. Crandell, of Taunton; The Association of Anæmia with Chronic Enlargement of the Spleen, by Dr. A. H. Wentworth, of Boston; Cretinism, by Dr. Charles S. Millet, of Brock-

ton; and The Pupil as an Index of Disease, by Dr. E. E. Jack, of Boston.

The order for the Section in Surgery, under the chairmanship of Dr. John C. Irish, of Lowell, is as follows: Stricture of the Oesophagus, by Dr. Theodore Dunham, of New York; Gastric Ulcer, by Dr. A. T. Cabot, of Boston; Gastric Cancer, by Dr. W. M. Conant, of Boston; Gall-stones, by Dr. M. H. Richardson, of Boston; Intestinal Cancer, by Dr. F. B. Lund, of Boston; and Obstructive Disease of the Lower Bowel, by Dr. H. O. Marcy, of Boston. The Shattuck Lecture will be given on Tuesday by Dr. William F. Whitney, of Boston, on the subject of the Alleged Increase of Cancer in Massachusetts.

The general meeting will be held in Chickering Hall on Wednesday, at which the following papers will be read: A Report of Cases of Cancer Treated by the X Rays, by Dr. F. H. Williams, of Boston; A Critical Note upon Clinical Methods of Measuring Blood Pressure, by Dr. W. H. Howell, of Baltimore, and Mr. C. E. Brush; Practical Blood Examination, by Dr. H. F. Hewes, of Boston; Problems of Bacteriological Laboratories which have to do with Public Health, by Dr. H. W. Hill, of Boston; The Origin of Oxalic Acid from Protein and Protein Derivatives, by Dr. A. E. Austin, of Boston; Intercranial Pressure after Head Injuries, by Dr. W. B. Cannon, of Boston; and A Statement of Original Work done in the Department of Anatomy of the Harvard Medical School, and a Description of a Model of the Abdominal Viscera, by Dr. Thomas Dwight, of Boston. The annual discourse will be delivered at noon by Dr. George E. Francis, of Worcester.

The North Carolina Medical Society has elected Dr. R. H. Young, of Concord, president; Dr. A. G. Carr, first vice-president, and Mrs. E. Dixon Carroll, M. D., third vice-president.

The Iowa State Medical Society has elected the following officers: President, Dr. J. R. Guthrie, Dubuque; vice-president, Dr. S. Bailey, Mount Ayr; secretary, Dr. V. L. Treynor, Council Bluffs; treasurer, Dr. G. L. Skinner, Cedar Rapids.

A Joint Session of Regular, Eclectic, and Homœopathic Physicians.—The Homœopathic Medical Society of Wisconsin, the Wisconsin Medical Society, and the Wisconsin State Eclectic Medical Society will meet at Waukesha, Wis., on June 27th, in joint session.

The Illinois State Medical Society has chosen Quincy as the next place of meeting, and the following officers have been elected: President, Dr. J. T. McAnally, Carbondale; vice-president, Dr. M. L. Harris, Chicago; second vice-president, Dr. J. W. Hensley, Peoria; secretary, Dr. E. W. Weis, Ottawa; assistant secretary, Dr. C. D. Center, Quincy; treasurer, Dr. E. J. Brown, Decatur.

The Arkansas Medical Society, at its recent session at Hot Springs, elected the following officers: President, Dr. F. Vinsonhaler, of Little Rock; first vice-president, Dr. C. R. Chenault, of Helena; second vice-president, Dr. W. N. Yates, of Batesville; secretary, Dr. J. B. Runyon, of Little Rock; treasurer, Dr. R. C. Thompson, of Pine Bluffs. The society will meet next year in Little Rock on May 13th, 14th, and 15th.

The Michigan State Medical Society, at its recent meeting, elected the following officers: President, Dr. Leartus Connor, of Detroit; first vice-president, Dr. B. D. Harison, of Sault Ste. Marie; second vice-president, Dr. Charles Douglas, of Detroit; third vice-president, Dr. H. W. Sawyer, of Hillsdale; fourth vice-president, Dr. L. P. Parkhurst, of Middleville; secretary, Dr. A. P. Biddle, of Detroit; treasurer, Dr. Charles E. Hooker, of Grand Rapids.

The Missouri Medical Association has elected these officers for the ensuing year: President, Dr. J. D. Griffith, Kansas City; first vice-president, Dr. R. E. Young, Jefferson City; second vice-president, Dr. J. C. Whaley, Osceola; third vice-president, Dr. R. M. Funkhauser, St. Louis; fourth vice-president, Dr. J. F. Campbell, Callao; fifth vice-president, Dr. G. W. Vineyard; recording secretary, Dr. B. C. Hyde, Kansas City; assistant recording secretary, Dr. F. W. Burke, Sedalia; corresponding secretary, Dr. Charles W. Fassett, St. Joseph; treasurer, Dr. J. Franklin Welsh, Salisbury. St. Joseph was chosen as the next place of meeting.

The Kentucky State Medical Society has selected Paducah as the place of the next meeting. The nominating committee presented the following names for officers, all of whom were unanimously elected: President, Dr. T. B. Greenley, Meadow Lawn; first vice-president, Dr. George M. Reddish, Somerset; second vice-president, Dr. B. L. Coleman, Lexington; secretary and treasurer, Dr. Steel Bailey, Stanford; librarian, Dr. Frank L. Lapsley, Paris. The same board of censors, consisting of Dr. J. B. Marvin, of Louisville; Dr. A. D. Price, of Harrodsburg, and Dr. B. N. Taylor, of Greensburg, were re-elected without opposition. Dr. Frank Boyd, Dr. Henry E. Tuley, and Dr. Steel Bailey were appointed a committee to revise the constitution, in line with the plans mapped out at the last meeting of the American Medical Association.

The National Association for the Study, Care, and Treatment of Epilepsy, at Washington, D. C., in its closing sessions elected the following officers: President, Frederick Peterson, M. D., of Craig Colony for Epileptics, at Sonyea, N. Y.; first vice-president, William P. Letchworth, of Portage, N. Y.; second vice-president, William Osler, M. D., of Baltimore; treasurer, H. C. Rutter, M. D., of Gallipolis, Ohio; secretary, William P. Spratling, M. D., of Craig Colony, Sonyea, N. Y. The members appointed to the executive committee were: Dr. W. N. Bullard, of Boston; Dr. Wharton Sinkler, of Philadelphia; Dr. W. F. Drury, of Virginia; Dr. William A. Polglase, of Michigan, and Dr. W. B. Warshan, of Texas. W. P. Letchworth was added to the executive committee as an honorary member.

The American Therapeutic Society.—The annual meeting of the American Therapeutic Society closed at Washington, D. C., on May 9th, to convene in New York in May, 1902. The officers chosen were: President, Dr. Reynold Webb Wilcox, of New York; first vice-president, Dr. Howard H. Barker, of Washington; second vice-president, Dr. Thomas E. Satterthwaite, of New York; third vice-president, Dr. Leon L. Solomon, of Louisville, Ky.; secretary, Dr. Noble P. Barnes, of Washington; recorder, Dr. William M. Sprigg, of Washington; treasurer, Dr. John F. McLean, of Washington;

curator, Dr. George C. Ober, of Washington. The four last named were reelected.

The Æsculapian Medical Society of the Wabash Valley, at its recent meeting at Mattoon, Ill., elected the following officers: President, Dr. J. A. Baughman, of Neoga; vice-president, Dr. F. D. Lydick, of Paris; secretary and treasurer, Dr. H. McKennan, of Paris.

The Albany (N. Y.) County Medical Society held its annual meeting recently. These officers were elected: President, Dr. W. H. Murray; vice-president, Dr. Andrew MacFarlane; secretary, Dr. Harry S. Pearse; treasurer, Dr. W. H. George; board of censors, Dr. Henry Hun, Dr. J. L. Archambault, Dr. J. F. Featherstonhaugh, Dr. G. E. Lochner, Dr. T. L. Carroll; delegates to the New York State Medical Society, Dr. Pearse, Dr. Theisen, Dr. Case, Dr. Bartlett, Dr. Babcock, Dr. Murray, Dr. Archambault, Dr. Sautter, Dr. Sabin, Dr. C. H. Moore, Dr. Elting, Dr. Carroll, Dr. Ryan, Dr. E. Vander Veer, and Dr. Shaw.

The Steuben County (N. Y.) Medical Society held its eighty-fourth annual meeting recently and elected the following officers for the ensuing year: President, Dr. J. G. Kelley, of Hornellsville; vice-president, Dr. W. W. Smith, of Avoca. The following were elected delegates to the State Medical Society Convention at Albany, in January, 1902: Dr. F. H. Cobb, of Corning; Dr. J. G. Kelley, of Hornellsville; Dr. T. H. Pawling, of Bath; Dr. C. B. Stevens, of Wallace; Dr. W. W. Smith, of Avoca; Dr. W. E. Walker, of Hornellsville; Dr. J. L. Miller, of Corning; Dr. A. J. Switzer, of Bradford. The next meeting of the society will be held at Corning on the second Tuesday in October, 1901.

The Chicago Society of Internal Medicine gave its annual banquet in that city on May 16th. Dr. William Osler, professor of medicine in Johns Hopkins University, was the guest of honor. Dr. John A. Robison, president of the society, presided. Dr. James B. Herrick responded to the toast, "Our Guest." Dr. Lewellys F. Barker read a paper on The Foundation Stones of Medicine; Dr. Walter S. Christopher discussed The Tendencies of Modern Medicine; The Surgery of Medicine was the subject of a paper by Dr. John B. Murphy. Other papers were: Music in Medicine, by Dr. Norval H. Pierce; Chicago Medicine, by Dr. Frank Billings; and The Finalities of Medicine, by Dr. William A. Evans.

Camden County (N. J.) Medical Society.—The annual meeting of the Camden County (N. J.) Medical Society was held on May 14th at Camden, N. J., and the following officers elected: President, Dr. William R. Powell; vice-president, Dr. J. Doron; secretary, Dr. Paul M. Mecray; treasurer, Dr. E. R. Ramsdell; historian, Dr. H. H. Sherd; reporter, Dr. J. Doron; delegates to the American Medical Association, Dr. W. S. Jones, Dr. Joseph L. Nicholson, Dr. M. K. Mines, Dr. W. B. Jennings, Dr. Joseph S. Wills, Dr. G. S. Kirk; delegates to the New Jersey State Medical Society, Dr. William H. Ireland, Dr. Joseph S. Baer, Dr. John F. Leavitt, Dr. J. W. Martindale, Dr. Clarence Donges, Dr. William A. Wescott, and Dr. J. W. Fithian.

The Trustees of a Hospital in Asia Minor Meet in New York.—The first meeting of the board of trustees of the American Christian Hospital, at Cesarea, Asia

Minor, which was incorporated by a certificate filed at Albany, N. Y., on May 14th, was held in New York on May 17th. The officers elected were: President, Allison Dodd; vice-president, Samuel T. Carter, Jr.; secretary, Charles E. Manierre, 31 Nassau Street, and treasurer, James M. Speers, 14 West Twenty-third Street. The board was incorporated to hold the property and give perpetuity to the work of the Rev. Dr. William S. Dodd. The small dispensary over a stable, with which he began in 1886, has now grown to a fine stone hospital building of three stories, capable of accommodating seventy beds. Since the work began over two thousand operations have been performed, and the whole number of patients exceeds sixty-one thousand. Up to the present time the personal friends of Dr. Dodd have supplied most of the money necessary for carrying on the work, but it has now grown to such proportions that the board will seek for it a somewhat wider support.

The Army Sanitarium at Fort Bayard, N. M.—There are now 149 patients undergoing treatment at Fort Bayard Hospital for Consumptives, instituted about a year ago by Surgeon-General Sternberg. This establishment is the only one of its kind in the country devoted to military and ex-military patients. While at first looked upon rather as an experiment, such promising results have been obtained that it is now regarded as an institution. Fresh air, and plenty of it, is deemed the first essential in the treatment, with brisk walks in the invigorating atmosphere, plenty of sunshine, and nutritious food. For patients not able to walk about there is a solarium or "sun parlor."

A number of patients have so closely approached complete recovery that they have been discharged to duty, and a majority have shown marked improvement. While the hospital is for the use of the army, discharged soldiers are kept on the rolls of the institution. Of the 149 patients mentioned, sixty-four are ex-soldiers.

A British Congress on Tuberculosis will be held in the Queen's Hall, London, from Monday, July 22d, to Friday, July 26th, next. The work will be divided into four sections, as follows: (1) State and municipal, under the presidency of Sir Herbert Maxwell, M. P.; (2) medical, including climatology and sanatoria, Sir Douglas Powell presiding; (3) pathological, including bacteriology, president, Professor Sims Woodhead; (4) veterinary (tuberculosis in animals), president, Sir George Brown. In addition to the work of the sections, public addresses will be given to the whole congress on Tuesday, July 23d, by Professor Koch, of Berlin; on Wednesday by Professor Brouardel, of Paris; on Thursday by Professor McFadyean, of the Royal Veterinary College; and on Friday there will be a final meeting to pass resolutions. In connection with the congress it has been decided to form a temporary museum illustrating the pathology, treatment, or prevention of tuberculosis, consisting of: Section I, pathological and bacteriological preparations and specimens illustrating tuberculosis in man and animals; and Section II, plans and models of hospitals and sanatoria, charts and documents bearing upon the historical, geographical, and statistical aspects of the subject. It is hoped that any preparations or specimens in connection with work contributed to the congress will be exhibited in the museum. Among the questions to be discussed are the age and sex distribution of phthisis, the influence of housing and aggregation, the milk supply, sanatoria, climatology, the therapeutic and diagnostic value of tuberculin, etc.

Commencement Exercises.—The thirty-third annual commencement exercises of the Bennett Medical School, Chicago, took place on May 7th. There were thirty-eight graduates.—The commencement of the Medical College of Virginia took place at Richmond on May 9th. There were forty-five graduates.—The annual commencement of the Detroit College of Medicine took place in that city on May 9th.—Twelve students graduated at the commencement of the Eclectic Medical College of the City of New York on May 7th.—The exercises attending the thirty-eighth annual commencement of the New York Medical College and Hospital for Women were held on May 13th at the Assembly Hall, No. 156 Fifth Avenue.—The eighty-second annual commencement of the Medical College of Ohio was held on May 7th at Cincinnati. There were sixty graduates.—The commencement exercises of the medical department of Howard University, Washington, D. C., were held on May 7th. There were nineteen graduates.—The class day exercises of the Women's Medical College, Philadelphia, Pa., were held on May 15th.—A class of five graduated at the annual commencement of the Pulte Medical College at Cincinnati, Ohio, on May 7th.—The commencement exercises of the Long Island College Hospital were held in Brooklyn on May 14th. The class numbered forty-one.—The commencement exercises of the Laura Memorial Women's Medical College at Cincinnati, Ohio, were held on May 1st. There were five graduates.—The commencement exercises of the Medical Department of the University of Buffalo, N. Y., were held in that city on April 26th.—Nine students graduated from the College of Medicine and Surgery at Chicago on April 27th, when the annual commencement was held.—The University College of Medicine of Richmond, Va., held its annual commencement on May 2d. There were seventy-two graduates.—The Marion-Sims Medical College, of St. Louis, held its commencement exercises on May 2d. There were thirty-two graduates.—The twenty-ninth annual commencement of the College of Physicians and Surgeons was held at Baltimore, Md., on April 29th, the graduating class numbering fifty-nine.—The commencement exercises of the Wisconsin College of Physicians and Surgeons were held at Milwaukee on May 11th. There were eighteen graduates.—The Hahnemann Medical College, Philadelphia, commencement was held on May 15th. There were fifty-two graduates.—The seventy-sixth annual commencement of the Jefferson Medical College, Philadelphia, was held on May 15th. Degrees were conferred on 142 graduates.—The annual commencement of the Woman's Medical College, of Philadelphia, was held on May 16th. There were thirty-seven graduates.—The commencement of the class of 1901 of the Georgetown (D. C.) University School of Medicine was held on May 21st. There were twenty-one graduates.

Hospital Buildings and Endowments.—Improvements, to cost about \$45,000, are to be made in the Homœopathic Hospital, Brooklyn, during the summer.—It is expected that the new New York College and Hospital for Women, ground for which was broken recently in West One Hundred and First Street, will be ready for use next summer.—The Michigan Legislature has passed a measure appropriating \$50,000 for the establishment of a psychopathic ward at Ann Arbor State University.—Plans for the new Charlotte Williams Hospital, at Richmond, Va., which is to cost \$150,000, have been approved. It is expected that it will be completed by June, 1902.—The work of making interior

improvements in the Homœopathic Hospital, Brooklyn, will, it is expected, begin early in June. The improvements should be completed in time to permit the opening of the hospital as a city institution about October 1st. The estimated cost is \$45,000.—It is reported that the National Society of Locomotor Ataxia Sufferers, of New York city (Sidney McIntosh, 43 West Thirty-fourth Street, chairman of executive committee), is contemplating the erection of a hospital and sanitarium near Buffalo, N. Y.—The new building erected for the free sanitarium for consumptives by the Montefiore Home for Chronic Invalids at Bedford, Westchester county, N. Y., will be formally opened on Memorial Day.—The New York Homœopathic Medical College and Hospital has taken title to the five-story building at No. 429 East Sixty-third Street, paying for it \$23,500. It has been used as a hospital for some time.—A new hospital, to be devoted to the cure of consumptives, is to be erected in Chicago. It will be known as St. Anne's and will cost \$150,000.—Adrian Iselin is erecting a \$50,000 sanitarium on the Scarsdale Road, near Yonkers Park, N. Y. It is now nearly completed and will be formally dedicated to Bellevue Hospital as a home for its convalescing patients. The building is four stories high.—Anson R. Flower, of New York, has contributed \$25,000 to the Flower Hospital for the purchase of the building now occupied by it as a dispensary and dormitory.—The Misses Wright, of Boston, have given \$10,000 for an annex to the Dickinson Hospital, of that city, while for another annex \$5,000 has been given by Thomas M. Shepard.—Governor Odell, of New York, has signed Senator Davis's bill appropriating \$100,000 for the proposed hospital for consumptives in the Adirondacks.—A site has been secured for the Coney Island Emergency Hospital. It is a two-story frame structure and it is expected that it will be altered in time to receive patients early in June.—The Stony Wold Sanitarium, a semi-charitable hospital and infirmary for women and children consumptives, of New York, has been incorporated.—The sum of \$15,000 has been given by a New York woman, who prefers to remain unknown, to St. Peter's Hospital, at Roswell, New Mexico.—Plans have been prepared for the new Pay Hospital for Contagious Diseases at Philadelphia, and it is expected that it will be in operation next fall.—Improvements, to cost \$6,000, will shortly be made to Mercy Hospital, Chicago.—M. M. Alphonsa Lathrop, O. S. D., of St. Rose's Home, New York, has sent out an appeal for aid to erect or lease a permanent home for destitute cases of cancer among men. The sum of \$3,000 has already been secured.—The formal opening of the Hospital of the Chicago Eye, Ear, Nose, and Throat College took place on May 11th.—Officials of the Brooklyn Rapid Transit Company are discussing the advisability of establishing a hospital for the reception of persons who meet with accidents incidental to the running of the great transit system. The idea was suggested by Mr. Chamberlain, superintendent of shops and repairs, who organized a hospital on similar lines for the New York Central Railroad in Buffalo. The company owns property near its shops, at Fifty-second Street and First Avenue, Brooklyn. It is proposed that these buildings be remodeled and a part of the space be devoted to the requirements of a first-class emergency hospital.—Property has been leased in Atlanta, Ga., for a new Presbyterian hospital.—The laying of the cornerstone of the new Mount Sinai Hospital, Fifth Avenue and One Hundredth Street, New York city, took place with appropriate ceremonies on May 22d.—The citizens of

Pontiac, Mich., are planning to locate a hospital there.—The Ashtabula (Ohio) Medical Society is sponsor for a movement that is likely to result in a commodious modern hospital being established there.—The plans for the improvements at the Government Hospital for the Insane, at Washington, D. C., provide for sixteen buildings, the total cost of which will be between \$900,000 and \$1,000,000.—A fund has been started for the new Hebrew Hospital at South Brooklyn, N. Y. It will be called the Tilly Wendoehl Hospital.—The site for the new Harlem Hospital has been chosen. It will be on Lenox Avenue, between One Hundred and Thirty-sixth and One Hundred and Thirty-seventh Streets, New York city.—By the admission to probate, on May 20th, by Surrogate Abbott, in Kings county, of the will of Maria Sprague Meeker, the Brooklyn Home for Consumptives will receive her residuary estate, amounting to about \$12,000.—The medical profession of Church Hill, Va., has organized the Chimborazo Hospital Company. The company is to have a capital stock of from \$5,000 to \$25,000, divided into \$25 shares. A charter will be applied for shortly.—The directors of the Jordan Hospital, at Plymouth, Mass., have decided on a site for the new hospital donated by Eben D. Jordan, of Boston.—John D. Rockefeller, of New York, has subscribed \$5,000 toward a hospital at Duluth, Minn.—A new building, to replace the main structure of the Long Island College Hospital in Brooklyn, which was put up fifty years ago, is soon to be erected at a cost of over \$175,000, of which about \$120,000 has already been contributed. Henry W. Maxwell, it is said, has subscribed \$50,000. George Foster Peabody and Edward M. Shepard are also large contributors to the building fund. Plans are now being drawn for the new structure, which will be four stories in height and will be equipped in a modern manner. The new building will be flush with the street.

Births, Marriages, and Deaths.

Married.

CHASE—MORSE.—In Montclair, N. J., on Tuesday, May 21st. Dr. Carroll Chase, of Brooklyn, and Miss Charlotte C. Morse.

LEE—BOND.—In Chicago, on Wednesday, May 22d, Dr. John A. Lee, of Brooklyn, and Miss Penelope S. Bond.

SHEPARD—NORRIS.—In Manasquan, N. J., on Wednesday, May 22d, Dr. Charles Carter Shepard, of Colorado Springs, and Miss Louie Mae Norris.

STIVERS—HOMMEL.—In Port Jervis, N. Y., on Thursday, May 23d, Dr. Moses A. Stivers, of Middletown, N. Y., and Miss Lillian Chapman Hommel.

Died.

BRITTIN.—In Athens, Illinois, on Friday, May 17th. Mrs. Nancy D. Brittin, mother of Dr. William A. Brittin, of Auburn Illinois, and of Dr. A. L. Brittin, of Athens.

CULVER.—In Boston, on Thursday, May 23d, Dr. Jane Kendrick Culver.

HOUGH.—In Toronto, Ontario, on Thursday, May 16th. Dr. Herbert J. Hough, of Midland, Ontario, in the twenty-seventh year of his age.

HOY.—In Albion, N. Y., on Tuesday, May 21st, Dr. Susan U. Hoy.

RUMBOLD.—In St. Louis, on Thursday, May 23d, Dr. Thomas F. Rumbold, in the seventy-first year of his age.

THOMAS.—In Baltimore, on Tuesday, May 21st, Dr. William D. Thomas, of Richmond, Virginia.

WEINGES.—In Jersey City, on Thursday, May 23d, Dr. Conrad Weinges, in the fifty-third year of his age.

WELLS.—In Englewood, N. J., on Tuesday, May 21st, Dr. John A. Wells, in the forty-sixth year of his age.

WILLIAMS.—In Cincinnati, on Saturday, May 18th, Dr. Thomas Williams, in the ninety-third year of his age.

Pith of Current Literature.

Boston Medical and Surgical Journal, May 23, 1901.

Municipal Care of the Consumptive Poor. By Dr. S. A. Knopf.—The author views the care of the consumptive poor as counseled not only by ideas of humanity, but as forced upon us by purely economic considerations. The truth is already demonstrated that the hygienic and dietetic treatment of pulmonary tuberculosis is feasible everywhere, where the extremes of temperature are not too pronounced, and where the air, soil, and general environments are sanitary. The fact that consumption is far more often associated with poverty than with affluence is demonstrated, and the frightful mortality of consumption is shown by the fact that, in the city of Boston, eleven per cent. of the mortality is due to it. However, an early recognized case of tuberculosis has from sixty to seventy per cent. of chances of cure. Post-mortem statistics show that twenty-five per cent. of people who die of accidents or diseases other than tuberculosis reveal on autopsy positive evidences of absolutely healed pulmonary lesions. Not only are State sanatoria a necessity, but municipal sanatoria are equally so, and for the benefit of those who cannot be convinced by indirect proofs, the author proves that by treating a consumptive patient in a sanatorium or special hospital, where he has from fifty to seventy-five per cent. of chances of cure, instead of treating him in a general hospital, where his chances of cure, in spite of the best of care, must be considerably less, the Commonwealth saves on each patient \$4 for every week when treated in a sanatorium.

Echinococcus of Liver, with Perforation into the Lungs and Bronchi. By Dr. William F. Gay.—In this case, intercurrent disease fully met all the prominent symptoms and prevented a positive diagnosis until rupture occurred and the cysts were microscopically demonstrated. The temperature never reached above 101° F., except during the pneumonia, when it reached 102° F. Other points of interest were the high pulse rate uninfluenced by the temperature, the peculiar orange-colored masses in the sputum, the absence of pleuritic involvement at the time of perforation, and the presence of the cysts.

Massachusetts General Hospital. Clinical Meeting of the Medical Board (concluded). Case Operated on for Exaggerated Roman Nose. Plastic of Hand. Plastic of Arm. Enteroptosis. A Case of Myxœdema and Arrested Development.

Medical Record, May 25, 1901.

Orchitis and Epididymitis in Typhoid Fever. By Dr. Francis P. Kinnicutt.—The points emphasized are: 1. Epididymitis or orchitis occurring in the course of or during the convalescence from typhoid fever is a rare lesion and is of typhoidal origin. 2. Only very exceptionally is it due to secondary microbial infection. 3. It develops at a late period in the disease or during convalescence. 4. The lesion, although, as a rule, unilateral, may be bilateral, and involves either the epididymis or testicle or both, and not infrequently the cord. 5. Effusion into the tunica vaginalis is rare. 6. Termination is most often by resolution. 7. Suppuration occurs in twenty-five per cent. of all cases. 8. Localized necrosis and extrusion of testicular tissue are not uncommon.

9. Exceptionally there is destruction of the entire testicular structures. 10. Atrophy of the testicle occurs, but is a rare sequence. 11. The lesion gives rise to little constitutional disturbance. 12. Death, as a direct result of the lesion, has not been noted.

The Operative Treatment of Umbilical Hernia in Adults. By Dr. Joseph A. Blake.—In cases in which there is stretching of the linea alba, with separation of the recti, the author believes the method of lapping the abdominal wall to be particularly applicable. The more apparent advantages are: 1. The doubling of the abdominal wall at the hernial site. 2. The breaking of the lines of suture. 3. The broad surfaces for union. 4. The obliteration of the separation of the recti and the reduction in the size of the abdomen. Its field is really not limited to herniæ proper, but also includes the treatment of pendulous abdomens and of enteroptosis due to laxity of the abdominal wall.

The Borderland of Insanity: Where and What is it? By Dr. Henry Waldo Coe.—The author refers particularly to those cases which, allowed to continue unchecked, tend to drift off into those mental disorders named by Krafft-Ebing the psychoneuroses, a class of mental disorders, even when fully developed, subject often to relief under the application of rational therapeutic, hygienic, and environal measures. Much space is taken up with the sexual phase of the subject, because the author regards it as the most important causative factor touching the borderland of insanity.

Recurrent Oculomotor Paralysis: Report of Case, with Remarks. By Dr. William M. Leszynsky.

Medical News, May 25, 1901.

Some Notes on Medical Diagnosis. By Dr. William N. Berkeley.—The author quotes Montaigne to the effect that the physician "hath need of many parts, divers considerations, and severall circumstances to proportion his desseigne justly. . . . God knows how hard the knowledge of most of these parts is." In an article of great merit he preaches the faith of thoroughness, and he cannot conceive that we should do as *little* scientific work as we can, but as *much*. Whatever the scheme of examination, let it be thorough, and constantly practised, for we are safe in the possession of no virtue until its practice has become habitual. One of the general logical laws on which diagnosis proceeds is the "Law of Parsimony." "Causes are not to be multiplied beyond necessity." We should choose, however, not always the smaller number of causes, but the number of causes that explain the phenomena most satisfactorily. Eternal vigilance is the price, and a good rule for the medical man is to send his patients to the surgeon or the *post-mortem* room with a written diagnosis. He will be often enough laughed at, but he will gain enough to compensate him for the ridicule. And he may console himself by remembering that the surgeons and pathologists, for all their scorn, have fields of labor of their own, where they, too, like us, are groping in darkness, and only by slow degrees feeling their way to the light.

The Mineral Waters of Mt. Clemens, Michigan, as Viewed and Compared with those of European Watering Places. By Dr. Richard Leuschner.—The author regrets that, whereas German, Austrian, and European resorts in general, enjoy the distinction of being conducted on a scientific basis, at American watering places there is as yet ground for improvement in this respect.

The Treatment of Chronic Purulent Otitis Media. By Dr. James F. M'Kernon.—We should never lose sight of the fact that we are medical practitioners first and specialists second, and all these cases, when indications demand it, should have general building up and tonic treatment, in order that the local condition may improve the more rapidly.

Tuberculosis of the Iris. By Dr. William F. Mitten-dorf.

Journal of the American Medical Association, May 25, 1901.

The Pathology of Active Tuberculosis of the Peri-cardium. By Dr. H. Gideon Wells.

Tuberculosis of Fascia. By Dr. J. Clark Stewart.—The author believes that tuberculosis of fascia occurs with sufficient frequency to entitle it to more attention than it has received in the past. It occurs in two well-marked forms, and the recognition of these forms is essential to its proper surgical treatment. Fibrous tissue associated with, and resulting from, tuberculous infection is to be viewed as tuberculous tissue, and treated accordingly. Such fibrous tissue may, in some cases, need the test of animal inoculation to absolutely prove its tuberculous character.

Sarcoma of the Pancreas. By Dr. George A. Boyd.

A Case of Epithelioma Developed on the Basis of a Healed Lupus Vulgaris Treated by X Rays. By Dr. David Lieberthal.

Ureteral Implantation into the Bowel for Diversion of the Urine. An Experimental Research. By Dr. Jacob Frank.—From his experiments the author concludes that bilateral implantation into the rectum simultaneously is primarily and remotely an extremely dangerous procedure, and can have no favorite place in human surgery. While no single permanent implantation of the ureter into the rectum has demonstrated an absence of inflammatory reaction on the part of the kidneys, the author believes that it is only justifiable where other means fail, and that it has but a limited place in pelvic surgery. While stricture did not take place, yet it cannot be said that scar contraction at the opening into the rectum will not, in months or years, produce one. That the rectum will tolerate the presence of urine cannot be doubted.

An Overlooked Nasal Factor in Ear Disease. By Dr. Chevalier Jackson.—In this article the author refers to the often-observed hypertrophic thickenings on both sides of the vomer, near the posterior free margin, which deflect the inrushing blast of dust-laden, dry, cold air against the Eustachian eminences, resulting in perpetual irritation of the mucous membrane in the vicinity of the tube mouths. As to treatment, there can be but one indication, and that is to take off the air-deflecting projection and let the inspiratory blast go back and strike against the posterior pharyngeal wall, as Nature intended.

Compound Fracture of Olecranon, with Dislocation of both Bones of Forearm. By Dr. B. N. Torrey.

Tubercular Disease of the Knee-joint and Hip-joint in Children. Diagnosis and Treatment. By Dr. Edward A. Tracy.

Cough due to Reflex Irritation in the Upper Air-passages. By Dr. Frank S. Milbury.—The author's con-

clusions are those also of Mayer. A cough is reflex in its origin: 1. When it is spasmodic, practically constant, without, or with but little, expectoration and temperature. 2. When the physical signs of the pulmonary disease are absent. 3. When it persistently resists all medication for permanent relief. 4. When the general health remains comparatively undisturbed. 5. When, upon removal of the cause, it promptly ceases. Often, in conjunction with the local, general treatment as well is necessary. Digestion and alimentation and all neurotic conditions should have the most careful consideration.

Appendicitis in a Child Less than Two Years Old. By Dr. George W. Newton.

Philadelphia Medical Journal, May 25, 1901.

The Surgical Treatment of Chronic Ulcer of the Stomach. By A. W. Mayo Robson, F. R. C. S.—The author speaks of the method of employing the decalcified bone button. The advantages he mentions are: 1. It provides an opening of the exact size intended, with no possibility of the passage being made too small by the drawing up of the sutures before the knots are tightened. 2. It provides immediately an open channel between the two anastomosed viscera. 3. The bobbin protects for from twenty-four to forty-eight hours the new line of union from pressure and from the irritation of the visceral contents. 4. It facilitates the application of the sutures. 5. No foreign material is left in the alimentary canal which may irritate or cause subsequent trouble, for the bobbin rapidly dissolves in the alimentary juices. 6. This method has been proved by ample experience to be rapid, easy, efficient, and safe. For stomach operations it is used in gastro-enterostomy, in pyloroplasty, in gastroplasty, and in pylorotomy or partial gastrectomy, and in the latter operation it is unnecessary to use more than two continuous sutures for the whole operation.

Late Results of the Treatment of Inoperable Sarcoma with the Mixed Toxines of Erysipelas and Bacillus Prodigiosus. By Dr. William B. Coley.—The risks of this treatment are practically nil, if proper precautions are observed. In upward of two hundred cases the author has had but two deaths. He points out that the method is advised only in inoperable tumors, and practically only in sarcoma; in other words, in the entirely hopeless cases. The percentage of probable cures depends largely upon the type of cell, varying from perhaps four or five per cent. in the round-celled to nearly fifty in the spindle-celled variety. Success has not followed the treatment in melanotic sarcoma. While the treatment is not recommended in carcinomatous growths, it has been the experience of the author that in many cases the toxines exert a marked inhibitory influence in carcinoma, although it is rarely curative. The author explains the action of the toxines upon malignant tumors upon the theory that such tumors are the result of some infectious micro-organism.

Trauma as an Exciting Cause of Paralysis Agitans. By Dr. F. Savary Pearce.—The conclusions which seem to be more definite as regards trauma as an exciting cause of paralysis agitans are that the later the origin of the disease, the more apt is trauma to have been the exciting cause; in any event, it is more apt to produce an aberrant type of the malady, especially when the insult to the nervous system has been primarily in the periphery of the body rather than of the central neurons.

Two Cases of Lobar Pneumonia following Ether Anæsthesia, with Unusual Course. By Dr. W. S. Schley.

Lancet, May 18, 1901.

The Pathology and Diseases of the Thyreoid Gland.

By W. Edmunds, F. R. C. S.—In the second of the Erasmus Wilson lectures upon this subject, the author first considers the effects produced upon animals by excision of the parathyreoid glands only. It has been asserted by some that parathyreoidectomy is more fatal than total excision of the thyreoid and parathyreoids, but the author's experiments do not bear out this view. The changes occurring in the thyreoid lobes left in these operations are interesting: The colloid diminishes or completely disappears, and its place is taken by a watery secretion; the vesicles, instead of remaining round, become branched and the secreting cells become columnar, or, multiplying, fill the cavity of the vesicles with round cells. These changes are identical with those known as "compensatory hypertrophy." This coincides with the view that the parathyreoid glands manufacture the secretion and the thyreoid glands store it. A study of the eye changes observed in these operations tends to support the suspicion that the parathyreoid glands are involved in the pathology of Graves's disease. The author goes on to study the effects produced by an excess of thyreoid gland in the system. In monkeys, large doses of thyreocolloid produce well-marked symptoms: Proptosis, dilatation of pupils, widening of palpebral fissures, erection of hairs on the head, the hair falling out in patches, paralysis of one or more limbs, emaciation and muscular weakness, and, finally, death from asthenia. Of the above effects, those produced on the eyes are caused mainly by action through the cervical sympathetic. The injection of thyreocolloid into thyreoidless dogs causes a rise of blood pressure, instead of a fall as in normal animals.

Cases Illustrating the Surgery of the Thyreoid Gland. By H. B. Robinson, M. S.—Two classes of cases are reported by the author: The first group consists of cases of parenchymatous goitres, with general enlargement of the gland, almost symmetrical, without any pulsation or other signs of Graves's disease. In young subjects a rapid increase in size not uncommonly takes place about the onset of puberty, and no doubt bears some direct relation to the awakening activity of the sexual organs. Three such cases are reported, in two of which thyreoidectomy was performed. Thyreoid extract was given in all three cases, and recovery took place in all. The second group of cases are the thyreoid gland adenomata, encapsuled tumors embedded in the gland substance as elsewhere. A unilateral enlargement is almost without exception due to an adenoma, especially if malignant disease can be excluded. There is usually a localized convexity in some part of the anterior surface of the gland, and if the enlargement is marked the trachea will be displaced to the opposite side. The development of these tumors is usually slow and pressure symptoms are rare. In dealing with these adenomata strict conservatism should be adopted. It is quite unnecessary to remove the whole lateral lobe. Five such cases are reported by the author, the results following operation being most satisfactory.

A Pharyngeal Pouch of Large Size Removed by Operation. By R. J. Godlee, M. S., and T. R. H. Bucknall, I. S.—The authors report the case of a man suffering from a swelling which looked exactly like an enlarged

gland on the left side of the neck, at the level of the hyoid bone in front of the sternomastoid. This was removed by operation and proved to be a large pharyngeal pouch. Such pouches probably all arise in connection with one or other of the visceral clefts, and the following varieties occur, depending on the position of the obliteration of the cleft: (1) It may remain open throughout its entire length, giving rise to a complete fistula; (2) no external opening may be formed and a pharyngeal pouch with a blind extremity may remain; (3) the internal aperture may be shut off from the pharynx, leaving a blind external fistula; and (4), both internal and external openings, being closed, a "dermoid" cyst of the neck may remain. It is very difficult to determine which of the visceral clefts is concerned in the formation of such a pouch, but many facts point to the congenital origin of pharyngeal pouches and fistulæ and to their probable connection with the visceral clefts.

Flies and the Science of Scavenging. By Dr. G. V. Poore.—In this article the author considers the genesis of flies and their relation to proper scavenging. He is a warm advocate of covering all the scavengings of a camp with earth as soon as possible. Such burial of fæces must be done methodically and carefully and with every attention to detail. Nitrification in the soil is the aim of the sanitarian as well as of the agriculturist. The author is opposed to the use of chemical disinfectants. These are expensive, generally evil-smelling, often poisonous, and lead to an increase of the material to be transported. Experiments have shown that from the point of view of the innocuous transformation of organic refuse into "soil" deep burial is a mistake. The use of quicklime in the treatment of excreta is quite unnecessary.

A Case of Symmetrical Retinal Detachment Occurring during Labor and Associated with Albuminuria, Resulting in Complete Recovery. By R. G. Hann, M. R. C. S., and R. L. Knaggs, F. R. C. S.

Is the Murmur of Mitral Stenosis Systolic or Presystolic in Rhythm? By Dr. H. Walsham.—The author has made use of the x rays in determining whether the murmur of mitral stenosis is systolic or presystolic in rhythm. He describes shortly what is seen of the action of the normal heart on the fluorescent screen and how to determine the beginning and end of systole. In cases of mitral stenosis, examined in this way, he finds that the thrill and the murmur which are characteristic of the disease are both distinctly presystolic in rhythm, thus agreeing with the generally accepted view.

Opothrapy in Gynæcology. By Dr. J. Phillips.—The author deals with the question as to whether there is any real ground for supposing that treatment with animal extracts is efficacious, and, if so, on what lines and in what manner it should be carried out. The three extracts considered are: (1) Thyreoid extract; (2) ovarian extract; and (3), mammary extract. The value of thyreoid extract in the amenorrhœa of obesity and myxœdema is well recognized. But the administration of ovarian and mammary extracts is surrounded by great uncertainty. The author has found ovarian extract to be of definite service in cases of natural and artificially induced menopause; but in amenorrhœa and dysmenorrhœa it has been of no value. It may be given by grafting the fresh gland under the skin, by subcutaneous injections of the organic extracts, or by the administration by the mouth or the rectum of ovarine tabloids or the

glycerine extract. The last method is the one to be preferred. Mammary extract is best given in the raw state, cow's udder being cut into thin slices and made into a salad.

Some Questions with Regard to Acute Middle-ear Inflammation. By Dr. P. McBride.—The author calls attention to the fact that there is a form of adenoids, producing no other trouble, which is responsible for recurring attacks of middle-ear inflammation. On examination with the rhinoscopic mirror, a layer of adenoid tissue is observed occupying the space between the Eustachian orifices and apparently pressing upon their margins. On digital examination, the lymphoid tissue will be felt, but there is not any great amount present. The attacks of ear trouble cease when the adenoid tissue has been removed. The author does not believe that the new method of plugging the meatus with aseptic dressing after the perforation of an otitis media is at all suitable for all cases, and still adheres to the use of the catheter and Politzer's bag. The question of mastoid operation should be considered wherever there is excessive discharge or a small perforation in a bulged membrane. Free incisions in the drum are only of temporary value in such cases. In operating it is of the utmost importance that the middle-ear structures be respected, and for this reason Schwartze's method should always be adopted where possible.

A Simple Form of Electrical Light and Heat Bath, with Eight Cases of Osteo-arthritis Treated by it. By F. C. Eve, M. B.—The apparatus here described consists of three thirty-two-candle-power electric lamps, fixed on an aluminum base and protected by a wire cage from contact with the skin of the patient or with the blankets forming the walls of the chamber. The temperature of the chamber gradually rises in from fifteen to twenty minutes to from 200° to 250° F. Even in the most obstinate cases of arthritis the pain always subsides at the end of an hour's baking. The author reports eight cases of rheumatoid arthritis in which the use of the "electrothermogen" was invariably followed by a reduction in the amount of pain and stiffness. Some of the cases, however, seem only to improve up to a certain point. The apparatus is cheap, light, portable, odorless, and convenient.

British Medical Journal, May 18, 1901.

The Lower Uterine Segment and the Contraction Ring. By Dr. W. J. Smylie.—(The Ingleby lecture.) An exact definition of the lower uterine segment is impossible, the nearest approach to it being that it is "a portion of the uterus which before parturition resembles the body, and after it the cervix." Its origin is still uncertain and four different theories are held at the present time with regard to it: 1. That it develops during pregnancy (*a*) from the lowest part of the corpus uteri; (*b*) from the upper part of the cervix. 2. That it forms only during labor (*a*) from the cervix uteri; (*b*) both from the body and the cervix. The structural division of the uterus into an upper contracting and a lower distensile portion is of the utmost importance in the first stage of labor. The lower part being weaker, it yields, and the lower pole of the ovum bulges into it, the lower segment embracing the presenting part so closely that nothing is forced between. As the os dilates, the lower segment is gradually changed from a hemisphere to a cylinder, and the child passes through it and is expelled. In the third

stage the lower segment and cervix form a thin-walled collapsible tube, which affords no support to the upper, which contains the placenta. The upper segment, therefore, sinks down into the pelvis. But when the placenta is expelled the upper segment rises above the umbilicus, and the lower segment can be felt above the pubes. The author has discarded Credé's method of placental expulsion and allows the uterus to expel the placenta unaided. There are three signs that expulsion has taken place: (1) Elevation of the fundus above the umbilicus; (2) elevation of the lower segment above the pubes; and (3) protrusion of the cord through the vulva. To observe the last sign more easily, it is advisable to tie a ligature at the vulva; when this ligature is found five or six inches away from the vulva the placenta has left the uterus.

Where the lower segment is not formed or where it is unduly weak, the membranes are exposed to undue strain and premature rupture. Prolapse of the cord is usually due to the failure of the lower segment to closely embrace the presenting part; some malpresentations are also due to the same cause.

The lower segment of the uterus is the part most frequently involved in rupture. In normal labor the contraction ring is dilated by the resistance of the uterine contents and the excentric tension of the longitudinal fibres of the uterus. Its contraction is therefore due to a loss of resistance in the uterine contents at the site of the ring, diminished excentric tension, and possibly to an abnormal development of the circular fibres of the ring.

The Dangers and Diagnosis of Breech Presentation and its Treatment by External Version toward the End of Pregnancy. By Dr. H. R. Spencer.—The mortality in children born by the lower extremities is very high. One of the causes of the death of the child in these deliveries is the low insertion of the cord relatively to the cervix, leading to its prolapse or to its being pressed upon during labor. Premature respiration may be aroused by the action of the external air upon that part of the body already born. The small, soft buttock takes the brunt of the labor instead of the larger and harder head; all the viscera are liable to be injured by the pressure to which their delicate tissues are subjected during the act of birth. Injuries to the lungs frequently cause the death of the child from pneumonia after a few days. The testis is an organ especially liable to injury during the birth by the breech, on account of obstruction of the spermatic veins by pressure, and of pressure by the fingers of the doctor. Sometimes a hæmatocele is formed either in the tunica vaginalis, processus vaginalis, or cord. Hæmorrhages into the muscles are very frequent in breech presentation. Hæmorrhage into the sternomastoid muscle, giving rise to the so-called "sternomastoid tumor," is a frequent example. The Prague method is a fruitful source of this injury and should never be employed.

The diagnosis of breech presentation is best made by abdominal examination; it gives certain results before the onset of labor at a period when the diagnosis by vaginal examination is difficult or impossible. The author describes the various steps of the abdominal examination and the points to be looked for. A valuable means of detecting the head at the fundus is by a movement of shaking or succussion with one hand. On grasping the fundus lightly with the left hand, the head can be tossed between the fingers and thumb with remarkable distinctness. Where a breech presentation is diagnosed at the eighth month of pregnancy, the author recommends

the performance of external version. He has performed this operation six times; the mothers were delivered, with head presentation, and recovered and the children survived. Some sort of abdominal belt should always be worn after the operation. Among the contraindications to external version are multiple pregnancy, flattened pelvis, dead foetus, and placenta prævia.

Some Instances of Cystic Affections of the Breast, with Remarks. By A. M. Sheild, M. B.—There are two important points which are significant of the diagnosis of cyst. The first is variation in size, the second variation in local tenderness. Nothing is more deceptive than to argue of the nature of a breast tumor from the condition of the axillary glands. Glandular enlargement may be absent in carcinoma and present in a cyst. The use of the exploring trocar and cannula is of great value in doubtful cases. If a cyst is found and its contents are clear and devoid of the elements of blood, the injection treatment may be carried out, but the cases for this method of treatment must be selected with great care. The author reports four cases of cyst of the breast, which illustrate these points. In one case there was distinct dimpling of the skin, contrary to the generally accepted teaching of Mitchell Banks that the skin over a cyst is quite free from dimples or depressions.

Some Remarks upon an Analysis of 5,000 Cases of Death from Malignant Disease. By Dr. E. N. Nason.—The author has analyzed 5,000 cases of death from malignant disease, and concludes that although, up to a certain age, increasing years, with presumably decreasing cell vitality, renders the individual increasingly liable to cancer, this is only true up to a certain point. There comes a time beyond which increasing age renders the individual less, and not more, liable to cancer. It looks as though a certain amount of vitality or activity in the special cells of the organs affected is necessary, or at least most suitable, for the production of a cancer, and that when this vitality is diminished beyond a certain point a greater stimulus is needed before a malignant tumor can be started. In the uterus the maximum liability is reached immediately after the cessation of functional activity.

All the predisposing causes of malignant disease resolve themselves into conditions in which the resisting powers of the individual cells have most probably been reduced. It is in just such a condition that the invasion of a parasitic organism might be expected to have most chance of success. So that one can hardly refrain from suggesting that the various so-called predisposing causes are simply conditions which prepare the soil for the advent and growth of some essential exciting cause, possibly a parasitic organism.

Erythema Multiforme and Vaccination. By Dr. N. Walker.—The author has observed four cases of erythema multiforme following vaccination, and holds that the vaccination was causally related to the skin eruption. Instances have been reported by other observers, and the author is inclined to adopt the suggestion of Gilchrist, that a toxine is produced by vaccination which, circulating in the blood, produces, as many other toxins do, that form of erythema which we know as erythema multiforme, and especially that variety described as erythema ris.

Deutsche Medizinal-Zeitung, May 6, 1901.

Bacteria of Food Preparations.—Dr. Bruno Schürmayer calls attention to the inconsistency of insisting

upon sterilized milk for infants and invalids, and of giving them food preparations containing milk which are, as he demonstrates, full of bacteria. He cites as diseases which may be transmitted by impure milk products, typhoid fever, cholera, tuberculosis, thrush, anthrax, and scarlet fever. Toxæmias may arise from toxins developed in the milk or imparted to it.

May 9, 1901.

Practical Experiences with Hydriatics in Measles and Scarlatina.—Dr. R. Putzer has found that, in suitable cases, hydriatic measures have made a good impression in these diseases upon the temperature, the pulse, and the diuretic action of the kidneys.

Münchener medicinische Wochenschrift, May 7, 1901.

Rheumatic Tendinitis Ocularis.—Dr. A. Pichler reports a case in which the tendon of the superior and inferior rectus muscles of the eye became inflamed in a rheumatic subject. The ailment yielded promptly to sweat baths and treatment by salicylates.

Diagnosis of Tumors of the Frontal Lobe.—Dr. Höniger reports the case of a man, fifty-four years of age, who began to have epileptic seizures about three years before his death. He was confused, had pains in the back and abdomen, and was not able to sit up in bed unassisted or to stand erect. While lying, however, he could easily move his limbs. The author correlates these, the principal symptoms, with the autopsy findings and points out the details of a possible diagnosis.

Tuberculous Meningitis in Tuberculosis of the Male Generative Organs.—Dr. M. Simmonds calls attention to the frequency of tuberculous meningitis accompanying tuberculous disease of the male genital tract. He has found the combination in one third of the cases he has examined *post-mortem*. He emphasizes the importance of the surgical removal of tuberculous foci in the genitals, to avoid this seemingly favorite complication.

Kissingen Baths in Heart Disease. By Dr. Leusser.

Curative Baths in Heart Disease. By Dr. Stiffler.

Bullet Wound of the Bladder. By Dr. B. Bayerl.

Extracranial Syphilitic Eye Diseases (concluded). By Dr. O. Schwarz.

Wiener klinische Rundschau, May 12, 1901.

Case of Spina Bifida Occulta.—Dr. Max Reiner, in reporting a case of this kind, says that the clinical diagnosis may be made when certain typical symptoms are present, including the maldevelopment of the spinal cord, its membranes and its bony covering, without the presence of a hernial protrusion. Myelocystocele of small size may lie deep in the fasciæ or in muscle or fat masses, so that they will escape clinical observation. The absence of a protrusion may be due to the interruption of the development of the sac. Myeloceles and meningoceles may remain small and, covered with normal skin, may appear only vaguely as small cysts.

Technics of Radiography (conclusion). By Dr. Peter Bade.

Therapeutic Value of Ichthyol.—By Dr. J. W. Frieser.

Wiener klinische Wochenschrift, May 9, 1901.

Clinical Diagnosis of Renal Infarcts (continued article). By Dr. Rudolf Schmidt.

Action of Suprarenal Extract upon the Nose and Larynx.—Dr. L. Harmer has used the suprarenal extract in solutions of ten and of fifty per cent. in Chiari's clinic. As an anæsthetic, he found it of great value, especially when it was not desirable to use cocaine. He was not impressed with its value as a hæmostatic, but he regards it highly in the treatment of the acute catarrhal conditions.

Tears of the Vaginal Vault during Labor (*conclusion*).—Dr. H. Ludwig has reported a large number of cases. He speaks of the complications, the sudden delivery of the child and the placenta, simultaneous laceration of the bladder, descent of the intestines, etc. Threatened vaginal rupture gives no definite symptoms, nor are the subjective symptoms often important. The usual objective signs are: Cessation of labor pains, disappearance of the presenting part of the fetal head, followed by the birth of the child and placenta, descent of the intestines, symptoms of beginning peritonitis, sensitiveness of the abdomen, vomiting, dyspnœa, collapse, rapid pulse, a grave facial expression; in other words, the physical signs which usually accompany rupture of the uterus. Hæmorrhage may appear externally, or may go on internally. The treatment must be directed toward the delivery of the fœtus and its appendages if it lies in the abdominal cavity, and toward closing the vaginal wounds surgically. Hæmorrhage is to be stopped by suture, drainage must be invariably practised to avoid infection, and, occasionally, hysterectomy must be performed. The prognosis is bad. Prophylactically, women with a pendulous abdomen must wear a binder throughout pregnancy, and must keep their bed and remain in the recumbent position during labor. The abdomen must be held up during the labor to secure the proper entrance of the fœtus into the pelvis. Operative measures on such patients must always be performed under anæsthesia and must be devoid of all force.

Gazette hebdomadaire de médecine et de chirurgie, May 9, 1901.

Adipositas Dolorosa.—M. C. Achard and M. C. Laubry report a case in a woman, seventy-nine years of age. They call attention to the main symptoms as observed by Dercum and themselves. The fat may be deposited symmetrically and is often in the form of nodular masses. The pain is severe and is increased by pressure. Sensation is disturbed, there is muscular atrophy or hypertrophy (in the hands), alopecia and brittleness of the hair are observed, hæmorrhages occur and psychic disturbances may appear. The origin of the disease is obscure.

Indépendance médicale, May 15, 1901.

Social, Economic, and Patriotic Views of Tuberculosis.—M. Samuel Bernheim makes an earnest plea for the establishment and maintenance of sanatoria and dispensaries for the treatment of pulmonary tuberculosis. He shows what the social and economic gain to the State would be under such a system, well regulated and well supervised.

Riforma medica, April 17, 1901.

Researches on the Active Substances in Cultures of the Bacillus of Typhoid Fever. By Dr. A. Paladino-Blandini.—Cultures of typhoid bacilli contain two substances which differ from each other chemically and bio-

logically—a nuclein and a nucleo-albumin. The property that these cultures possess, of conferring upon the blood of inoculated animals an agglutinating power, depends on the presence of a special nucleo-albumin. This nucleo-albumin is alone capable of conferring specific agglutinating properties on the blood of animals treated with it. This nucleo-albumin (like anti-arsenin, as observed by Bereska) does not act except through the medium of the white blood cells.

April 18, 19, 20, 22, and 23, 1901.

On the Therapeutic and Hæmatopoietic Action of Sodium Cacodylate. By Dr. Carlo Chiaporri.—The author found, from an experience with fourteen cases, that the action of sodium cacodylate is as follows: The injection of this drug is followed in from twenty-five to fifty-five minutes by an increase of the red cells amounting to from 600,000 to 1,160,000. This increase was not noted in three of the fourteen subjects, but these three were gravely anæmic. Only in one case was there no increase after injection of sodium cacodylate, although the degree of anæmia was not marked.

The increase of hæmoglobin is not proportional to that of the red blood cells. The drug has no influence upon the number of white blood cells. Successive counts of red blood cells established the fact that the new red cells in the blood which came after the injection of sodium cacodylate again disappeared in from one to four hours. It is probable that these cells are eliminated, and in order to determine this the author investigated the amount of urobilin excreted before and after the injection of the cacodylate. Urine, passed after the injection, was more highly colored than that passed before, owing to the increased amount of bilirubin, which also showed itself on chemical analysis.

Poggi, in a recent study, showed that young red cells may be recognized in the blood by a peculiar method of staining with methylene blue. The author found that in one case the blood contained ten per cent. of Poggi's corpuscles before the injection, and twenty per cent. after the injection of the cacodylate. From this it may be concluded that the increase in the number of red cells which results from these injections is attributable to the entrance of new red cells into the circulation, but this theory must be proved by further experiments.

April 24, 1901.

On Uretero-enteroplasty. By Dr. Niccola Giannettasio.—The author conceived the idea that the appendix vermiformis might be employed for the restoration of the continuity of a ureter where ureteroplasty was necessary. For this purpose he operated upon three rabbits the appendix being absent in most common domestic animals. He killed these animals after a time, and found the appendix in good condition, save in one case where a suppurative process had developed in its vicinity, as a result of imperfect asepsis. He removed the appendix closing the wound in the cæcum with Lembert sutures. The upper end of the ureter was then sutured into the open end of the appendix, while the other end of the ureter was sutured into the closed end after an incision had been made therein for this purpose. The sutures were applied accurately, according to Lembert's rules. The advantages of this method of ureteroplasty are stated to be as follows: There is less disproportion between the calibre of the ureter and the appendix than between the

ureter and other organs used for ureteroplasty. His method enables one to utilize an organ measuring seven or ten centimetres and not infrequently twelve or thirteen centimetres in length. The method is applicable in both sexes. It has the advantage of removing a useless and dangerous organ, and the operation in itself is less dangerous than all the other methods proposed. The author now proposes to study the influence of the bacteria in the appendix upon the kidneys after implantation.

April 25, 1901.

A Contribution to the Study of Acromegaly. By Dr. Giuseppe Finzi.—The author presents the history of a case of acromegaly and concludes as follows: The chief characteristics of this case, in addition to the acromegalic aspect, were: The supraciliary pain, the persistent winking, the exophthalmos, the atrophy of the optic nerves, the glycosuria and azoturia, the neuritic symptoms in the upper extremities, especially on the right side where there was muscular atrophy, the amenorrhœa, the anaphrodisia, and the general weakness. In all probability the lesion was a tumor of the hypophysis which compressed the posterior angle of the chiasm, causing bilateral temporal hæmianopsia.

Vratch, March 31 (April 12, New Style), 1901.

Memorial Number Devoted to the Late Viatcheslav Avskentievitch Manasseine, Editor of Vratch.—This number contains materials for a biography of V. A. Manasseine, who was professor of the practice of medicine in the Military Medical Academy of St. Petersburg. He was one of the most prominent figures in Russian medical affairs, and his journal, *Vratch*, has been noted for its independence and its strict ethics. He was especially interested in an association organized in aid of needy students and in associations of similar character for physicians. *Vratch* will be discontinued on January 1, 1902, in accordance with the last will of the deceased.

April 7 (April 19, New Style), 1901.

Haffkine's Lymph and other Remedies against the Plague in Man, which Produce an Active Immunity against the Disease. By Dr. A. F. Vigur.—The author has studied, experimentally and clinically, the various substances which produce active immunity against plague, with a view of determining the position of Haffkine's serum among these remedies. The question as to the location of the plague antitoxines and toxines is an important one, and it must be determined whether these substances exist principally in the bodies of the bacilli themselves or in the media in which these germs grow. Yersin, Calmette, and Borel, in 1895, showed that filtered cultures of plague bacilli were harmless, while injections of dead plague bacilli, taken from agar cultures, were deadly in animals, proving that the plague bacillus contained a toxine in its body. Subsequent investigations, however, showed that older cultures contained toxine in the filtrate; in other words, that after a while the nutrient medium became poisoned with the products of the germs. The immunizing property resided principally in the bodies of the germs. (*To be continued*).

Balantidium Coli as a Cause of Chronic Diarrhœa. By Dr. N. S. Solovieff (*concluded*).—The balantidium, by virtue of its motility, penetrates between the glands of the healthy intestinal mucosa, thence passes into the submucosa and multiplies therein, producing pathologic

changes, which have been described in the last issue. These parasites may also penetrate into the muscular layers and into the subperitoneal connective tissue. The generally accepted view that the balantidium lives only on the surface of the intestinal mucosa is, therefore, wrong. The presence of these parasites in the deeper layers of the intestinal wall accounts for the chronicity of the disease and for its tendency to relapse.

Gastrotomy for the Removal of a Foreign Body. By V. V. Rosanoff.—The foreign body in this case was a glass test tube, which the patient had swallowed. While in a state of intoxication, he had put a number of coins into his mouth, and suddenly felt a choking sensation. He bent down, and succeeded in getting out all of the coins except one, larger than the rest. Assuming that this last coin was arrested in his throat, he quickly seized a glass tube that lay close at hand, and pushed the coin down with it. He lost his hold on the tube and swallowed it; a week later the larger coin was found under a bench near the site of the accident. The operation was successful, and he recovered without any complications.

The Koumyss Treatment and Some Koumyss Settlements in the Ufa Government. By Dr. P. V. Zesarevsky.

Klinitchesky Journal, February, 1901.

On the Varieties of Gastralgia. By Dr. C. A. Ewald.—The author presents the histories of five patients with various types of gastralgia. Formerly, when there were no exact methods of diagnosis, all forms of pain in the stomach which recurred spasmodically were styled gastralgias or cardalgias. At present it is a recognized fact that the most diverse pathologic processes may be the cause of this pain. The author emphasizes the importance of a thorough general examination in all these cases. In three patients of the five presented there were Argyll-Robertson pupils and other symptoms calling attention to the possibility of nervous lesions, and hence, probably, gastric crises had to be dealt with. In one patient there was progressive general paralysis. In tabetics the gastric crises may be rendered worse by abuse of morphine. The other two patients did not show any nervous symptoms; in the first the pains were due to accumulation of food in the stomach as a result of the lack of gastric juice, and to spasmodic contractions of the œsophagus as a result of the hyperacidity of the contents. The last patient was suffering from chronic alcoholic gastritis, and the pains were due to irritation of the nerves of the stomach by food; they disappeared when the patient was fed by the rectum.

On the Surgical Treatment of Diseases of the Stomach. By Dr. A. P. Langovoy.

On Idiosyncrasy toward Quinine. By Dr. I. F. Gorbacheff.—It is difficult to determine in any individual case what dose of quinine will produce the maximum therapeutic effect without toxic symptoms. Quinine must, therefore, be given cautiously when large doses are required, especially when there is reason to suspect disturbance of the respiratory or circulatory functions. The author reports six cases of quinine idiosyncrasy, in which small doses of this drug produced unexpected disturbances. When such cases are met with, it is well to combine the quinine with some stimulant, such as strychnine, coffee, etc.; to give it in divided doses; to change the form of administration; to add bromides, hydrobro-

mic acid, or opium. If all methods fail, the drug must be stopped temporarily, or even permanently. In treating the untoward symptoms occasioned by the idiosyncrasy, the gastric disturbances, as well as the nervous and psychic symptoms, may be allayed with opiates, while ergot of rye is recommended for the eruptions. Ice on the head and narcotics proved useful in one of the author's cases.

Roussky Archiv Pathologii, Klinitcheskoy Meditsiny y Bakteriologii, February, 1901 (Russian Archives of Pathology, Clinical Medicine, and Bacteriology).

Cellular Poisons (Cytotoxines). By Dr. I. I. Metchnikoff.—The author gives an account of the investigations on the cytotoxines which have been made within the past three years. Cytotoxines are poisons of cellular origin, which at the same time act as toxic agents upon the cells. Bordet, in 1898, found that, while the serum of a normal guinea-pig did not affect the red blood corpuscles of a rabbit, the serum of a guinea-pig that had been inoculated several times with rabbit's blood destroyed the red cells of this animal. The substance which produces this destruction is styled hæmatoxine or hæmolysine. It has been further shown that this hæmolysine consists of two classes of substances. The first of these, the alexine, or, as the present author prefers to call it, "cytase," is very unstable and is destroyed by a temperature of from 55° to 56° C. The other, called "substance sensibilisatrice," or "philocytase," resists this temperature, and is destroyed only on heating to from 65° to 68° C. The combined action of both these substances is necessary in order to destroy the red cells of the rabbit. Philocytase is present only in the serum of animals that have been inoculated with blood (active serum), but cytase is present in normal animals in the same quantity as in inoculated animals. Hence the serum of a normal animal becomes hæmolytic when a certain dose of the serum of an inoculated animal is added to its blood. This is styled "rendering serum more active." Philocytase is called "substance sensibilisatrice" because Bordet supposed that this substance was not a destructive agent, but rendered the cells more sensitive to the cytase. The study of cytotoxines will be of great importance in the medicine of the future. In some diseases it will be necessary to administer anticytotoxines, in others the cytotoxines themselves. The author predicted in a former article that new growths would be treated by anticytotoxines which destroyed certain cells.

So-called Lipoma Arborescens. By Dr. N. N. Michailoff.—The so-called lipoma arborescens of various authors is not a lipomatous tumor, as has been stated. The ramified growth is simply the product of a chronic inflammation, a hyperplasia of the normal tissue of the synovial membrane, with an abundant fatty infiltration in the larger tumors. The most frequent cause of this inflammation is the slow action of the toxine of tuberculosis. The author describes a rare case (the seventh in literature) of such an arborescent lipoma in the tendons of the extensor carpi radialis longior in a man aged thirty-two years.

On Glycosolvol. By Dr. S. Levachéff.

A Method of Quantitative Determination of Urea in the Urine. By Dr. A. P. Braunstein.

Miscellaneous.

Ringworm Acquired from a Cat and Resembling Syphilides.—Mr. Pernet (*British Journal of Derma-*

tology, January; *Medical Age*, April 10th) presented to a recent meeting of the Dermatological Society of London the case of a woman, aged twenty-three years, who attended University College Hospital for circinate lesions of the face and body. Singly, and at first sight, some of the lesions were suggestive of a circinate syphilide. The patient had attended the department for syphilis seven years previously. She now had several disks from one half to one inch in diameter on the chest, nose, chin, and cheeks, and three on the neck. The eruption began on the end of the nose as a scratch. The most inflamed disk was on the middle of the chest, three quarters of an inch in diameter, with a well-defined border one eighth of an inch in width, flat and crusted. A smaller patch close by was commencing to clear in the centre. On inquiry as to animal infection, it was elicited that a kitten the patient handled had something the matter with its fur. The kitten was brought and examined, and denuded patches with stumps were found on its tail. A stump removed showed a white powdery sheath to the naked eye. Microscopically, this stump exhibited a sheath of small spores, indistinguishable from *Microsporon Audouini* as to size and arrangement. No trace of beaded elements. On the same slide three narrower stumps were seen. They had frayed ends, proximal and distal, with a sheath of spores starting from near the proximal, or root, ends and surrounding the stumps for some distance, but leaving a fair length of the distal end free. On pressing down the cover-slip the spores were detached in masses—no chain formation. Inside the stumps there were plain slender mycelial elements as in *Microsporon Audouini*, with spores external to stumps. It was noticed that the stumps broke up into longitudinal strands. Scrapings from the kitten's tail revealed masses of spores, no doubt from sheaths around the stumps, and a few epithelial cells here and there, but no mycelium was observed. Scrapings from the woman's lesions showed abundant mycelium. It was short, as a rule, with segmentation here and there. The filaments varied in size—some were coarse, others slender, branching, or budding, occurring laterally and at right angles to the main filament. These characters Mr. Pernet considers as belonging to the *Microsporon Audouini*. There were no graceful, long, dichotomously branching filaments as occur in large-spored ringworm. Cultures from the woman were unfortunately contaminated. The diagnosis arrived at was microsporon of the cat.

Letters to the Editor.

NOTES ON THE NOMENCLATURE OF BACTERIOLOGY.

1691 CAMBRIDGE STREET, CAMBRIDGE, MASS.
May 3, 1901.

To the Editor of the New York Medical Journal:

SIR: On this subject I should like to venture a few suggestions, which, though they may not merit approval may stimulate an increasing interest in furthering the establishment of accuracy and uniformity in the terminology of bacteriology.

In this important field it is a well-known fact that in spite of many years of study by thousands of our greatest intellects, with its consequent rich and vast literature, no definite system of classification has been agreed upon and adopted by our leading authorities for this class of vegetable organisms which lie in that bot-

derland illustrating the evolutionary continuity between animal and vegetable life.

Migula, one of our latest and highest authorities on bacteriology, in his *System der Bakterien*, gives a very able and critical *résumé* of the various systems of classification proposed, sees defects in each, and substitutes one of his own. Marshall Ward, *On Characters or Marks Employed for Classifying Schizomycetes*, expresses some very suggestive ideas on the same subject. Coppen Jones, in his translation of Fischer's *Structure and Functions of Bacteria*, says: "The different meanings attached to the words 'bacillus' and 'bacterium' deserve notice. In two of the most recent systems of classification the senses in which they are used have little in common. Lehmann and Neumann apply the word 'bacterium' to all rod-shaped forms in which spores are unknown. The genus 'bacillus' embraces those in which spores have been found, irrespective of the manner of ciliation. Migula, on the contrary, uses the term 'bacterium' for all non-motile rods, and 'bacillus' for the peritrichous species. Perhaps the best plan would be to drop altogether the word 'bacterium' as a generic term, seeing that it is now used as a collective name for the whole group of micro-organisms."

But, while the present state of our knowledge may not warrant the positive adoption of any one system of classification, nevertheless, it is to be borne in mind that the classification first based on morphological characteristics of bacteria, though crude and incomplete, has given rise to their distinctive names as bacillus, coccus, spirillum, etc. This leads me to the consideration of the point I wish especially to call to the attention of the medical profession, for not only are the various more or less well-known names of certain bacteria used according to individual preference by various writers, differing naturally in different languages, but the inconvenience of long names has quite commonly led to abbreviations (*B. tuberculosis* for *Bacillus tuberculosis*) or even simply the use of the qualifying adjectives (pyogenes aureus for *Staphylococcus pyogenes aureus*). But, worst of all, in a recent number of the *Medical Record* the author of an exceptionally good and scientifically accurate article refers to the "spores of anthrax" (using the name of the disease for the name of the micro-organism)—all this for want of a recognized, uniform, really scientific, and practical nomenclature. Then, too, in consulting the literature of the *Bacillus anthracis*, for instance, one finds references under such a diversified list as this: *Metallactar anthracis*, *Bacillus anthracis*, *Bacillus du charbon*, *Bacterium anthracicum* (or *anthracis*), *Milzbrandbacillus*, anthrax bacillus, bactérie du charbon, bacillus of splenic fever, and bacillo del carbonchis. Though long usage and the consensus of opinion of most authorities have settled on the term "*Bacillus anthracis*" as the preferred specific designation, yet Migula, in accordance with his classification, has adopted as the name "*Bacterium anthracis*."

However, it seems to me that, so far as medical literature is concerned at any rate, the *Bacillus anthracis*, the *Bacillus diphtheriæ*, the *Bacillus tuberculosis*, and others will always be known as such. Now, in view of these inconsistencies and differences of opinion, can, nevertheless, all the above-mentioned be harmonized and put on a rational basis by such a modification of the present current nomenclature as will give distinctive scientific names which will find ready acceptance as common names, without introducing radical changes; such, moreover, as can be placed unchanged in any system of classi-

fication which may finally be adopted? This, I believe, can be done, and I submit for consideration a few suggestions, which I hope may find favor.

The principle is analogous to that used in chemical terminology, as exemplified by the terminations of such words as sulphate, sulphite, sulphide, nitrous, nitric, etc. The idea is simply as follows: To the first adjective of the approved name of each micro-organism add the termination "-us" for bacillus, "-cus" for coccus, "-lum" for spirillum ("-um" for bacterium, Migula), leaving the rest of the name, as regards qualifying adjectives, unchanged. Thus, in the names of bacilli, "-us" would simply be substituted for the terminal vowels and the endings -os, -is, -es, -us, -um, and for coccus (including micrococcus, staphylococcus, and streptococcus) "-cus" in place of terminal consonants. Similarly for the others. As examples: Anthracus (*Bacillus anthracis*), diphtherus (*Bacillus diphtheriæ*), lactus aerogenes (*Bacillus lactis aerogenes*), pyogenecus (*Streptococcus pyogenes*), pyogenecus aureus (*Staphylococcus pyogenes aureus*), and intracellularicus meningitidis (*Micrococcus intracellularis meningitidis*). For the sake of brevity it may be advisable in special cases to drop redundant adjectives and use simply the one most characteristic; so in the last instance the name would be "intracellularicus," or, more characteristic, "meningiticus" (in this case for euphony's sake, dis instead of s alone is dropped and cus added).

As with any innovation, the writer expects this at first to meet with some adverse criticism, but he would like, in conclusion, to point out these features and advantages, which may commend themselves to those interested in securing scientific accuracy with practical utility: The terms are distinctive, short, and logically practical, with no essential change in the terminology recognized and in common use. Being definite and concise, they obviate the inaccuracies and ambiguities so common in "scientific literature," as above detailed. But, above all, this method promotes *uniformity*, while giving a specific name which indicates the nature of the organism and at the same time is acceptable to whatever system of classification may be adopted finally.

THEODORE H. ROMEISER, M. D.

Book Notices.

A *Compend of Human Physiology*, especially Adapted for the Use of Medical Students. By ALBERT P. BRUBAKER, A. M., M. D., Adjunct Professor of Physiology and Hygiene in the Jefferson Medical College of Philadelphia, etc. Tenth Edition, Revised and Enlarged. With Illustrations and a Table of Physiologic Contents. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. viii-9 to 270. [Price, 80 cents.]

THAT this hand-book should have come to the tenth edition indicates its acceptability to students. The new issue shows many revisions in, and additions to, the text. Although it is intended as a quiz compend, there is much matter condensed, by the use of small type, into its reading pages. It is a concise, but very readable manual of physiology.

Anatomisch-klinische Vorträge aus dem Gebiete der Nervenpathologie. Von Dr. KARL SCHAFFER, a. ö. Professor der Nervenpathologie an der Universität zu Budapest; Ordinarius des hauptstädtischen, Elisa-

both Siechenhauses und der Poliklinik. Ueber Tabes und Paralyse. Mit 5 Tafeln und 63 Abbildungen im Text. Jena: Verlag von Gustav Fischer, 1901.

THE anatomy of the portions of the nervous system invaded by tabes and paresis, the philosophical consideration of some of the symptoms of these diseases, and the relationship between them are the subjects of these lectures. Many of these things are gone into in great detail, but, while the author has in the main brought together all the facts, he does not substantiate fully some of his points. For example, against the theory of the knee-jerk definite objections may be made, and he gives too much weight to the Nageotte theory of the pathology of the posterior spinal roots. The text is amplified by excellent plates, and the volume, while it contains nothing particularly new, is a useful addition to the library of the neurologist.

Hypnotism and Suggestion in Therapeutics, Education, and Reform. By R. OSGOOD MASON, A. M., M. D., Fellow of the New York Academy of Medicine, etc. New York: Henry Holt & Company, 1901. Pp. vii-344.

Hypnotism. A Complete System of Method, Application, and Use, prepared for the Self-instruction of the Medical Profession. By L. W. DE LAURENCE, Instructor at the School of Hypnotism and Suggestive Therapeutics, Pittsburgh. Illustrated. Chicago: The Henneberry Company, 1901. Pp. 5 to 256. [Price, \$1.50.]

THE subject of suggestive therapeutics seems to be attaining an increased interest in this country. Since last autumn no fewer than four monographs by American writers have appeared. The press almost daily chronicles the cure of some condition which had defied other remedies. We hear more and more about the universal application of hypnotic suggestion in education, in hysteria, in psychoses, and in other conditions. One might almost be led to suppose that we had been blessed with a new discovery. It seems to be forgotten that even while Mesmer was quarreling with the French Academy of Medicine in the eighteenth century hypnotism and hypnotic suggestion were being successfully used elsewhere, and also that before the discovery of ether or chloroform serious surgical and dental operations had been performed under suggested anæsthesia.

To-day we are called upon to sift the useful from the useless, and to determine in the light of wider experience the therapeutic applicability of suggestion. As a factor in the moulding of society and in the direction of human activity, the influence of one person on another, or suggestion, is practically limitless. On the other hand, the use of formal hypnosis intentionally induced in the patient by an operator for therapeutic purposes is restricted. Hypnotic suggestion may modify symptoms, but it cannot remake ancestry. It may give a better direction to the action of nerve force, but it cannot replace poor neurones with good ones. Its purpose is that of amelioration rather than of cure. It is very necessary for physicians who intend to look into the subject of suggestive therapeutics to realize its limitations. Its benefits and its usefulness will readily become apparent in practice. In well-chosen cases every practising physician will benefit by being able to employ it.

Of the two books before us, the first is the only one we would recommend to medical readers. Dr. Mason is a practitioner of experience, and has already identified

himself with psychological medicine in a previous publication. While his present volume shows some of the partiality of the enthusiast, it is none the less a conscientious exposition of what its author believes. Mr. De Laurence's book, while it gives some of the simpler psychological principles of hypnotism, is apparently written for those who are looking into the subject for such good as they may get out of it in their own cases.

Laryngeal Phthisis, or Consumption of the Throat. By RICHARD LAKE, F. R. C. S., Surgeon Laryngologist, North London Hospital for Consumption, etc. With Thirty-six Illustrations, Twenty-one of which are Colored. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. 94.

THE literature of tuberculosis is so voluminous that it seems hardly necessary to bring out a separate monograph upon merely one local aspect of it, but, after looking over the manual of Dr. Lake, we congratulate him upon the clear manner in which he has set forth the essential features of laryngeal tuberculosis. The subject is considered under the headings of predisposing causes, the part played by the nose, symptoms, liability to infection of the different parts of the larynx, associated lesions and their influence, primary laryngeal tuberculosis, treatment, pathology, etc. At the close of the book are given several clinical histories of illustrative cases and a tabulated list of 329 cases which have come under the author's observation. A formulary is also added. The manual is well worthy of perusal by all practitioners who treat cases of tuberculosis of the air-tract.

Lectures on Nasal Obstruction. By A. MARMADUKE SHEILD, M. B. (Camb.), F. R. C. S. (Eng.), Surgeon to St. George's Hospital, London, etc. With One Colored Plate and Twenty-seven Illustrations in the Text. Philadelphia: P. Blakiston's Son & Company, 1901. Pp. x-106. [Price, \$1.50.]

THE titles of the three lectures are, respectively, Causes and Diagnosis of the Principal Varieties of Nasal Obstruction, Treatment of Nasal Obstruction, and Treatment of Nasal Polypi. The wide latitude allowed by these titles enables the lecturer to touch upon many practical matters of daily clinical work, all of which are illumined by his lucid manner of presenting salient features and leaving untouched mere matters of historical interest or academic discussion. While the manual is designed primarily for students and junior practitioners, it may be read with profit by the general practitioner who has to meet certain emergencies in nose and throat work. The discussion of the question of adenoids and their removal is especially sensible. The illustrations are good, the type is clear, and the general appearance of the manual is distinctly attractive.

BOOKS, ETC., RECEIVED.

A Practical Treatise on Diseases of the Skin for the Use of Students and Practitioners. By James Nevins Hyde, A. M., M. D., Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, Chicago, etc., and Frank Hugh Montgomery, M. D., Associate Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, etc. Sixth and Revised Edition. Illustrated with 107 Engravings and 27 Plates in Colors and Monochrome. Philadelphia and New York: Lea Brothers & Company, 1901. Pp. xx-17 to 828.

Clinical Pathology of the Blood. A Treatise on the General Principles and Special Applications of Hæmatology. By James Ewing, A. M., M. D., Professor of Pathology in Cornell University Medical College, New York. Illustrated with 30 Engravings and 14 Colored Plates drawn by the Author. Philadelphia and New York: Lea Brothers & Company, 1901. Pp. xiii-17 to 432.

A Treatise on Orthopædic Surgery. By Royal Whitman, M. D., Instructor in Orthopædic Surgery and Chief of the Orthopædic Department of the Vanderbilt Clinic in the College of Physicians and Surgeons of Columbia University, etc. Illustrated with 447 Engravings. Philadelphia and New York: Lea Brothers & Company, 1901. Pp. xii-17 to 650.

A Manual of Diseases of the Nose and Throat. By Cornelius Godfrey Coakley, A. M., M. D., Clinical Professor of Laryngology in the University and Bellevue Hospital Medical College, etc. Second Edition, Revised and Enlarged. Illustrated with 103 Engravings and 4 Colored Plates. New York and Philadelphia: Lea Brothers & Company, 1901. Pp. 3 to 566.

A Reference Handbook of the Medical Sciences, embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, completely Revised and Rewritten. Edited by Albert H. Buck, M. D., New York. Volume II. Illustrated by Numerous Chromolithographs and 765 Half-tone and Wood Engravings. New York: William Wood & Company, 1901. Pp. v-1 to 838.

Public Water Supplies. Requirements, Resources, and the Construction of Works. By F. E. Turneaure, C. E., Professor of Bridge and Sanitary Engineering, University of Wisconsin; and H. L. Russell, Ph. D., Professor of Bacteriology, University of Wisconsin. With a Chapter on Pumping Machinery by D. W. Mead, C. E., M. Am. Soc. C. E., etc. First Edition. First Thousand. New York: John Wiley & Sons. London: Chapman & Hall, 1901. Pp. xiv-746.

Oral Surgery. A Text-book on General Medicine and Surgery as Applied to Dentistry. By Stewart LeRoy McCurdy, A. M., M. D., Professor of Anatomy and Surgery, Pittsburgh Dental College, etc. Pittsburgh: The Calumet Publishing Company, 1901. Pp. 3 to 368.

The Acute Contagious Diseases of Childhood. By Marcus P. Hatfield, A. M., M. D., Professor Emeritus of Diseases of Children, Northwestern University Medical School, etc. Chicago: G. P. Engelhard & Company, 1901. Pp. 5 to 135.

Traitement de la coxalgie par la mécanothérapie sans immobilisation au lit. Par le Docteur Paul Archambaud, Directeur de l'École Française D'Orthopédie et Massage, etc. Paris: Librairie de la Revue médicale, 1901. Pp. 32.

Die Impfung und ihre Technik. Von Hofrath Dr. med. Conrad Blass, Vorstand des Königlichen Impfstitutis und städtischer Impfarzt in Leipzig. Zweite durchgesehene Auflage. Leipzig: C. G. Naumann, 1901. Pp. 83.

Miscellany.

Iodoform as an Obscurer of the X Ray.—Professor A. Soret (*Revue médicale de Normandie*, April 10th) records a case in which thin patches of iodoform, which had been used in the dressing, adhering to a hand sub-

mitted to the x ray, gave rise on the skiagram to the appearance of spots suggesting the presence of foreign bodies in the tissues of the hand. Iodoform dressings, gauze, etc., in consequence of the great absorption by that drug of the x ray, should be avoided when skiagraphy is contemplated.

Sexual Irritability.—The *Medical Press and Circular* for May 8th says that it has been estimated that fully twenty-five per cent. of men are at one time or another afflicted with what we may call sexual irritability. They may roughly be divided into three categories: One is the man of the lithæmic type, of fair complexion, large stature, and flabby muscles, in whom defective elimination causes irritation of the urinary tract; a second group comprises the neurasthenics, who are prone to great variations of emotional excitement, the sexual emotion exhibiting the same lack of control as the others; lastly, we have those whose genito-urinary tract is the seat of chronic irritation of gonorrhœal origin. Medicinal and hygienic treatment usually prove effectual, provided that the disturbance is referred to its special source, so that a correct appreciation of the probable ætiology is of extreme importance.

The Secretion of Milk.—Budín (*L'Obstétrique*, November, 1900; *American Journal of the Medical Sciences*, April, 1901) gives several practical points obtained by clinical observation of the secretion of milk. He calls attention to a not uncommon class of cases in which the secretion of milk becomes established, but is for some time not sufficient to meet the needs of the child fully. Experience has shown that if the child is nourished by suitably prepared cow's milk, and the mother is allowed to nurse the child in addition, both do well. The child ceases to lose in weight, but gains, and the mother in a few weeks has an increased secretion of milk, which usually enables her to dispense with artificial feeding. He is opposed to abandoning the nursing of the child because the secretion of milk may not be abundant. He would supplement the mother's supply, giving the mother proper nourishment, and would hope and expect that later she would be completely able to feed the child. He also calls attention to the fact that the supply of breast milk varies in accordance with the child's needs. This is demonstrated by comparing the weight of the child with the quantity of milk furnished and also by observing the secretion of milk in the case of twin pregnancies. Here the supply increases to meet the needs of the two children in proportion with their growth. He narrates some interesting cases in which the secretion of milk has been resumed after a considerable pause.

The Psychology of Swearing.—"Most profane expressions," says the *Medical Press and Circular* for May 8th, "are the fossil remains of religious terms or ejaculatory prayers, and the history of profanity is intimately bound up with the history of religion. What interests us from a psychological point of view is less the origin and precise significance of profane expressions in general use than the reason for their employment. It is held by some that profane objurgations are instinctive or imitative relics of the habit of our wild ancestors of simulating the cries of ferocious animals and of uttering sounds calculated, by their harshness or their volume, to inspire terror. By and by came the time when certain words became sacred by reason of their religious associations, and their employment in verbal warfare would, it was

hoped, cause fear by reason of their awful associations, or, later still, because their unconventional use being severely punished, the deed savored of reckless violence. A few centuries later men took to utilizing the anathemas of the Church for their private purposes, and sought to inspire fear by evoking images of torture and endless suffering. The angry primitive man tried to shock his enemy by calling on thunder and gods; and the angry modern man consigns him, in tones of awful wrath, to eternal punishment. From the shock of terror there came the shock of temerity in taking holy names in vain, so that the greater the reverence of names of saints or places or deity, the greater is the shock to the man sworn at, and, presumably, the greater the relief to the man swearing."

The University of Michigan.—The first summer session of the medical department of the University of Michigan will begin on Monday, June 24th, and continue till August 9th. Twenty-one courses in twelve subjects are offered. These courses are classified as special, designed for graduates and advanced students, for which no credit will be given, and credit courses which duplicate certain portions of the curriculum and on the satisfactory completion of which credit will be given. No allowance for time will, however, be given for work done in the summer. A student cannot, therefore, shorten his residence in college by attending one or more summer sessions.

In *medicine* three courses are offered. Course 1, on clinical medicine, will be given by Dr. James R. Arneill. It is arranged especially for graduates, but is open to students who have passed their junior examinations. Course 2, a demonstration course with practical exercises in medical diagnosis, is also given by Dr. James R. Arneill. This course is the same as that given to junior students in the regular session. Course 3, on modern gastric methods, is to be under the direction of Dr. David M. Cowie, and is designed especially for graduates and advanced students.

In *surgery* two courses are offered, one by Dr. Cyrenus G. Darling and the other by Dr. Darling and Dr. Thomas S. Burr. Course 1, on clinical surgery, is designed for graduates and advanced students; no credit toward graduation will be given. Course 2 is a demonstration course in surgical technique and bandaging. It is the same as the demonstration course in surgery given to the junior students in the regular session.

In *ophthalmology*, course 1 will be on clinical ophthalmology and will be given by Dr. Flemming Carrow and Dr. Guy L. Noyes. The course is arranged for practitioners and advanced students. Course 2 is a demonstration course in ophthalmology, given by Dr. Guy L. Noyes.

In *diseases of the nervous system* three courses have been arranged. Course 1, on clinical neurology, will be given by Dr. William J. Herdman, Dr. Jeanne C. Solis, and Dr. Theophil Klingmann. It is a course designed primarily for practitioners. Course 2, by Dr. Klingmann, will deal with the pathology of the central nervous system. It is a course for graduates and advanced students. Course 3, by Dr. Jeanne C. Solis, is a demonstration course in nervous diseases. It will cover the same ground as that given to the students of the junior year in the regular session.

In *clinical dermatology and syphilology*, the course by Dr. Breakey, is arranged for practitioners or advanced students who desire to review, or especially prepare themselves in cutaneous medicine or syphilology.

In *pathology*, course 1 will be a laboratory course, by Dr. Alfred S. Warthin, the same as that given to junior students. It covers the ground of general pathology as given in Ziegler's text-book. Course 2 will be a special course in pathological technique, by Dr. Alfred S. Warthin.

In *electrotherapeutics* a course in laboratory work will be given by Benjamin F. Bailey. It will be so arranged as to give the students a practical acquaintance with the physics of electricity, its relation to physiological action and its applications in therapeutics.

The *anatomy of the nervous system* will form a course to be given by Dr. Robert C. Bourland. It will consist of lectures and laboratory work.

In *physiology* a laboratory course has been arranged to be given by August E. Guenther. It is intended to meet the demands of students of medicine, dentistry, biology, and those specializing in physiology or psychology, while for teachers of physiology in secondary schools it forms a valuable training.

In *physiological chemistry* two courses are offered. Course 1 is laboratory work under the direction of Charles L. Bliss. Course 2 will be advanced work. This will also be given by Charles L. Bliss and will consist of analysis of food stuffs and drinking water, and the examination of tissues for some of the more common poisons.

A *laboratory course in bacteriology* will be given by Dr. Frederick G. Novy and William G. Carhart. This course will be the same as that required of medical students.

In *histology*, Dr. Lydia M. De Witt has arranged for two courses. Course 1 will be the same as that given in the regular session of the medical department, and will consist of recitations and laboratory exercises. Course 2 will be on *microscopic technique*.

Courses in *chemistry, physics, biology, German and French* are given in the summer session of the literary department, the dates for which for the current year are the same as those for the summer session in the medical department.

Special announcements, giving full particulars regarding the courses of the several summer sessions of the University and the fees for each, can be had on application to the secretary of the university.

A Case of Successful Moral Treatment of a Form of Hysteria.—At a meeting of the New York Neurological Society, held on May 7th, Dr. Mary Putnam Jacobi reported the case of a woman of twenty-four belonging to a neurotic family. Her symptoms had begun four years before her coming under observation, with endometritis and uterine retroflexion. She had been subjected to a good deal of local treatment, including curetting and an Alexander's operation. The latter procedure had relieved the dysmenorrhœa, but had been followed by a fixed pain in the abdomen, not increased by pressure. She professed to be unable to walk or stand, because of severe pain in the back and abdomen which it induced. Examination showed no motor inability, and when started to walk she could walk very readily and energetically. The uterine disease had entirely disappeared. She was moderately anæmic and quite constipated. The speaker said that at some portion of the cerebrospinal tract an area of nerve tissue must have been so nearly on the border of exhaustion that an attempt at function carried it beyond this line. It was conceivable that with the exhaustion of the cerebral centre the very thought of the movement would be followed by pain. According to

Sanier, such hysterical pains pointed to a partial anæsthesia in the brain. Apart from the intermittent pains excited by the sense of walking, there seemed to be a permanent and distressful sense in the back, that of requiring support. In a previous experience with a bed-ridden patient, she had succeeded in making her walk within a week by the application of a Taylor spinal brace. This simple device had given great relief. The necessary nerve stimulus had been secured by the application of static electricity. This remedy seemed to be almost a specific for hysterical pains. The subject of the present report had been persuaded to leave her home and take a room near Dr. Jacobi's office. At first it was not difficult to get her to walk a portion of a block, but when finally asked to walk a whole block she obstinately refused. All sorts of changes in the treatment and methods of management were necessary in order to conquer the patient's wilfulness, yet this was essential to further progress. Her mode of life for each day was mapped out most minutely. By the most persistent and painstaking efforts exerted for a period of four months the patient was finally conquered. During the last eighteen months she had been living a fairly normal life. Dr. Jacobi said that in hysterics the habitual dependence upon fellow minds was immensely intensified. To rid them of a false idea, it must be starved out and atrophied by an entire lack of support from the minds of those around the patient. The essential element of the treatment in this case had been the bringing of the personality of the patient under the control of another mind.

The New Medical Laboratory of the University of Pennsylvania.—The new medical laboratory which is to be erected by the University of Pennsylvania, at Philadelphia, at a cost of over \$500,000, will be without a rival in completeness and equipment. It is to provide for the teaching of students and carrying on research in the subjects of physiology, pathology, and pharmacodynamics, in which departments of medicine the greatest advances have been made in the past and may be predicted for the future. The trustees are also contemplating the erection, in the future, of a new medical hall, anatomical building and auxiliary buildings, which will adjoin the new laboratory and form one of the most extensive systems of buildings devoted exclusively to the teaching of medicine either in Europe or America.

The new building will be quadrangular in shape and will be located on the south side of Hamilton Walk, between Thirty-sixth and Thirty-seventh Streets. It will be two stories in height above a high basement, and measure 340 feet front by nearly 200 feet in depth. The long front will face north, securing a maximum amount of the best light for laboratory purposes. All along the front are to be arranged small rooms for research, rooms for professors and their assistants, a library, etc., all opening into a private corridor, so that men employed in these rooms may pursue their work without interruption. Perfect lighting of all the laboratories will be secured, the courts being large enough, with the low front building, to furnish good north light to the laboratories.

The first floor of the new laboratories will be devoted to physiology and pharmacodynamics. To the former will be assigned one large laboratory for practical instruction, one for general research work, twenty rooms devoted to sub-section teaching, research work, rooms for professors, etc. The section devoted to pharmacodynamics will consist of one large laboratory for practical pharmacodynamics; a laboratory, 44 feet by 142 feet, for teaching practical pharmacy; another for general phar-

macodynamics, 44 feet by 65 feet; besides a museum and ten rooms for original research work, etc. The rooms in the basement of the building will be used for demonstration work. The second floor will be devoted exclusively to pathology. The entire north front of the building is to be devoted to laboratories for advanced students in pathology and pathological bacteriology, and to the special research and assistants' rooms. Each of the advanced laboratories will measure 31 feet by 44 feet. The east wing will accommodate the laboratory of experimental pathology, while the west wing will be occupied by the museum of pathological specimens. This latter, which is to measure 44 feet by 65 feet, will adjoin the demonstration hall of morbid anatomy, which will communicate with the general pathological-histological laboratory. The last laboratory, the front of which is to consist almost entirely of glass, will be located in a section of the building looking north into a spacious court. This room, 37 feet by 100 feet, will seat one hundred students, and will be devoted entirely to microscopical work. Another section of the building, of equal size with the first, and also looking north into the court, will be subdivided into three smaller laboratories for the instruction in comparative, neurological, and surgical pathology. The same method of lighting, with enormous glass windows, is to be carried out in this group of laboratories. Finally, the west wing of the building will also provide for photographic and microphotographic outfits. The laboratory is so designed that ample space will be available for expansion.

There will also be four lecture rooms in the building, which will each seat 185 students. These lecture rooms will communicate with two preparation rooms each. At the rear of the building there will be two large lecture rooms, each seating 400 students.

The most modern apparatus will be employed in lighting, heating, and ventilating the building.

A Louisville Physician Sues University which Dismissed him.—Dr. Dudley S. Reynolds, one of the founders of the Louisville Hospital College of Medicine and a member of its faculty from its inception, has been dismissed from the institution because of his antagonism to cigarette smoking. He is now suing Central University, of which the medical school is a part, for \$15,000 damages. Dr. Reynolds, in his lectures to his classes, denounced cigarette smoking and smokers in unqualified terms. The students took offense and refused to attend his lectures unless an apology was made. This he declined to do. At a meeting of the junior and senior classes of the Hospital College of Medicine, held subsequently to take action on the charge made by Dr. Reynolds that the faculty of the school had acted with the students in their boycott of him, the president of the senior class, in discussing the matter, said: "The faculty had nothing whatever to do with the boycott of Dr. Reynolds. He made objectionable and obnoxious statements to the students and they made up their minds to ignore him entirely. We petitioned the faculty for a successor to Dr. Reynolds, and if they had not removed him we would have left the school."

Neutral Red as a Means of Detecting the Presence of the Bacillus Coli Communis in Water-supplies.—Dr. William Hunter showed (*Lancet*, March 2d) that the use of neutral red, as suggested by Rothberger, afforded a reliable method of distinguishing the *Bacillus coli communis* from the *Bacillus typhosus*, and, further, that it was possible to diagnosticate by means of this method

with certainty the presence of the *Bacillus coli communis* in the majority of fluids within from twelve to twenty-four hours. He now states (*Lancet*, April 13th) that Dr. Makgill has made some experiments with the object of finding whether this reaction affords a means of detecting the *Bacillus coli communis* in water-supplies and of estimating thereby the number of bacilli present. The following is a summary of the results obtained:

Media containing neutral red form an extremely delicate test for the presence of the *Bacillus coli communis*. This is most marked in the case of peptone bouillon, in which the presence of one or two bacilli will produce a reaction within twenty-four hours if other micro-organisms are excluded. In water containing the ordinary varieties of aquatic micro-organisms the reaction is delayed unless comparatively large numbers of the *Bacillus coli communis* are present. Thus, if a cubic centimetre of unsterilized tap-water, containing from ten to twenty colon bacilli to the cubic centimetre, were mixed with the neutral red bouillon, a reaction would be present in twenty-four hours, but, if the bacilli numbered only from three to four to the cubic centimetre, their presence might not be shown until the second day had been completed. By noting such differences in time as varying amounts of the water to be examined require, a fairly accurate idea of the proportions of the colon bacillus present can be gained. By making shake cultures with one or two cubic centimetres of water in neutral red glucose agar, and incubating at 37° C. for two or three days, the colon bacillus can be detected and can be readily isolated when present in extremely small numbers. The reaction in broth has so far proved to be specific. In glucose agar, however—*i. e.*, under anaerobic conditions—the *Bacillus tetani* and the *Bacillus maligni œdematis* produce a reaction similar to that of the *Bacillus coli communis*. Notwithstanding this fact, the value of the reaction in regard to the presence of the *Bacillus coli communis* in water-supplies is scarcely affected. Dr. Makgill intends to publish soon the results of his experiments more in detail.

To Avoid Prickly Heat.—Major R. R. H. Moore, R. A. M. C. (*Journal of Tropical Medicine*, May 1st), says that, having begun to use cocoanut oil gently rubbed into the skin to allay the irritation of prickly heat, and finding it both pleasant and inoffensive, he was encouraged by a paper by Mr. Frederick Pearse (see abstract in *Medical Journal*, July 29, 1899, p. 173) to use the oil more extensively and to abandon the use of soap in the bath. Since then he has been able to keep free from prickly heat, though living in the steamy climate of Lower Bengal. He has also obtained a number of converts to this treatment, many of whom speak of it most enthusiastically.

There is, however, a strong prejudice against re-nouncing such a national institution as soap, and a still stronger one against adopting what many are pleased to term the filthy native habit of anointing one's skin with oil. Like other prejudices, these are without reasonable foundation.

It is quite possible to clean oneself in the bath without the assistance of soap, for "soap is only required when bathing is neglected." At first when soap is given up the pleasure and satisfaction of the bath is somewhat diminished, the hand no longer glides smoothly over the body in a creamy lather, it sticks unpleasantly, the contact is distasteful and the epidermis peels off visibly. This discomfort is only temporary; after a time the skin

becomes firm and glossy, and the hand glides over it as before, with the difference that the smoothness is now the smoothness of a firm, healthy skin, not the meretricious smoothness of an injurious compound the antecedents of which are doubtful.

Major Moore has not tried the mixture of lanoline and almond oil recommended by Mr. Pearse, for he finds cocoanut oil a clean, non-greasy oil specially adapted for the skin. Fresh cocoanut oil has only a faint smell; when rubbed into the skin this disappears almost, if not quite, entirely, though, if kept too long, the oil turns rancid, and stinks abominably. The fear of spoiling the clothes is also groundless; the skin absorbs the oil. It is not like oiling a piece of metal; after two or three minutes' gentle rubbing the oil disappears.

The best time to put it on is before going out for the evening's exercises; strip, pour a little of the oil into the palm of the hand, and rub it over the body from the neck to the ankles, and get your servant to rub the back. It is not advisable to use sponge or rags, which are not easily cleansed and so become offensive. When done, rinse your hands in plain water and dry. If necessary, they can then be washed with soap.

When you come in to dress for dinner, take a bath, using no soap. This is the time when you will appreciate the benefits of the oil. You find you can dry yourself perfectly; the skin is not, as is usually the case in steamy climates, sodden and clammy, it is, on the contrary, firm and glossy; you can pass your hand over it with a sense of pleasure, you have also a pleasant sense of coolness, and you can proceed to dress without breaking out into fresh perspiration. There is no reason why the oil should not be used twice a day if necessary; about a tablespoonful each time.

Major Moore does not think that the application of the oil interferes with the activity of the sweat glands. He is not sensible of any diminution of perspiration, but takes exercise as freely as ever. He agrees with Mr. Pearse that the excessive activity of the sweat glands is not the direct cause of prickly heat. He believes it to be an irritation of the skin produced by the constant bath of perspiration in which the body is kept in hot, muggy climates. This brings it into line with intertrigo and the so-called "flannel rash," eruptions caused by irritating secretions from the body.

Its distribution he holds to be largely accidental, influenced to a great extent by clothes, their nature, amount, and manner of being worn; and also by the obesity of the individual. The places it selects are those where perspiration tends most to collect.

The skin is naturally intolerant of prolonged exposure to moisture, Nature's protective greasy coat offers but a feeble resistance, and in steamy climates it rapidly becomes sodden. The evil is increased by removing the greasy coat by the use of soap, and keeping up a constant vapor bath by means of flannels. The result might readily be anticipated.

In climates where the diurnal ranges of temperature are great, flannels no doubt are useful, but in Lower Bengal in the rains, when the temperature varies but little and the atmosphere is saturated with moisture so that evaporation is reduced to a minimum, they do more harm than good. The cholera belt is a sure producer of prickly heat under these conditions.

Major Moore then considers that the rational treatment of prickly heat lies (1) in preserving Nature's protective coat by abandoning the use of soap, and (2), in reinforcing it when necessary by some lubricant.

THE NEW YORK MEDICAL JOURNAL, JUNE 8, 1901.

THE ADDRESS OF THE PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION.*

By CHARLES A. L. REED, A.M., M.D.

CINCINNATI.

In approaching the discharge of my duties as presiding officer of the fifty-second session of the American Medical Association, I beg to express my appreciation of the generous suffrages by which I have been called to a position of such conspicuous honor. This appreciation becomes all the more pronounced when I reflect upon the magnitude and achievements of this great national body and upon the lustre of the distinguished men who have presided over its deliberations. This thought brings me to the first duty of the occasion, and that is, officially to bring to your attention the fact that since our last reunion three of my most illustrious predecessors have been called from their worldly activities to the realm of rewards. Alfred Stillé, Lewis A. Sayre, and Hunter McGuire, each a former president of the association, died within a single week. Their lives were known of men, their records are ornaments of our annals, and their achievements are their eulogies. They labored zealously and with beneficent results, not alone in the scientific field, but in behalf of an organized national profession; and to guard zealously the splendid legacy which they, among others, have left us, must be one object of our labors upon this auspicious occasion. The hope is indulged that steps may be taken to procure suitable portraits of these and of other deceased presidents of the association, to be placed in some safe gallery until such time as the association may be able to transfer them to its own Temple of Fame. I recommend that suitable formal action be taken on this occasion relative to the life, distinguished services, and the death of these lamented confrères.

FOREIGN RELATIONS OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association accredited delegates during the last year to several foreign medical conventions, notably the International Medical Congress at

*Delivered at the Fifty-second Annual Session of the American Medical Association, at St. Paul, Minn., June 4, 1901.

DR. CHARLES A. L. REED, President of the Association.

Paris, the Dominion Medical Association of Canada, the Mexican National Association and the Pan-American Medical Congress at Havana. To each of these organizations the American Medical Association sustains relations of peculiar intimacy. As one of the great scientific nations of the earth, the United States is naturally an integral part of the International Medical Congress. This association, by a resolution presented by your present executive officer, took the initiative in 1891, in organizing the Pan-American Medical Congress. The first reunion of that congress was held in Washington in 1893, under the presidency of the late lamented Dr. William Pepper. The second was held in the City of Mexico in

1896 under the presidency of Dr. Carmona y Valle, while the third has been held during the last few months in the city of Havana under the distinguished presidency of Dr. Juan Santos Fernandez. This movement has for its object the establishment of closer relations between the medical profession of the different countries of the Western Hemisphere. It has already borne excellent fruit in the increased patronage of our medical schools from the far South, in the improved status of American medical practitioners in Latin America, in a better understanding of quarantine questions in the different countries, and in the development of a concert in the investigation of the medicinal flora of the Western Hemisphere. Our relations with the medical profession of Canada must be of in-

creasing intimacy, and I indulge the hope that while maintaining the national limitations of our association for delegate and legislative purposes, its membership, with the privilege of participating in all scientific matters, may be freely opened to our brethren who live beyond our immediate borders.

FISCAL AFFAIRS AND THE JOURNAL.

It has passed into unwritten law, born of the gradually developing features of our organization, that your president shall restrict his annual address to a discussion of the affairs of the association and to the great object to which, by the terms of its constitution, it stands consecrated—"the common interests of the medical profession in every part of the United States."

In compliance with this rule, and realizing that I am leaving scientific questions to be presented by orators appointed for the purpose, I have pleasure in calling your attention to the satisfactory condition of the affairs of the association, as indicated by the consolidated report of the treasurer and of the board of trustees. From it you will observe that under the judicious management of your board of trustees you had a cash balance at the end of the last fiscal year of \$31,004.67, being an excess of \$3,696.66 over the preceding year. Your plant has been increased in value to the amount of nearly \$10,000, and the net profits of the *Journal* amounted to nearly \$14,000. You will be gratified to realize that, in addition, you have safely invested as part of a fund with which to buy a home for the *Journal* and for the association the respectable sum of \$25,000. If, however, you have occasion to feel satisfied with the normal condition of your finances, you must contemplate with pride the rapid increase of your *Journal* in quality, size, circulation, and influence. The average weekly circulation grew, during the last fiscal year, from 13,672 to 17,446, and I have added pleasure in informing you that, since the period covered by the report, the weekly circulation has grown to 22,000 copies. For the accomplishment of these splendid results, I feel that you will join me in hearty acknowledgment, not only of the sagacious management by the board of trustees, but the tireless industry and the discreet direction of our accomplished editor, Dr. George H. Simmons.

I feel that it is important, however, to call your attention to the fact that it would have been impossible for your board of trustees to have accomplished these results if, through its action, the association had not become incorporated. Leases were to be executed, purchases were to be made, contracts were to be entered into, money was to be loaned, and bonds were to be exacted, to do all of which it was necessary that the association should become a legally organized corporation. This was effected, *ad interim*, by the action of your board of trustees, which procured articles of incorporation under the laws of Illinois, bearing date of April 14, 1897. I am not aware that this fact, attested by the document which I have laid before the executive committee, has ever been confirmed by the vote of the association. I recommend, therefore, that such action be taken at the present session.

If, however, the condition of the association, and particularly of the *Journal*, is, on the whole, occasion for much satisfaction, certain facts revealed by the report are food for thought. Thus, the *Journal* has an aggregate circulation two and one-half times greater than the aggregate membership of the association. It would seem, therefore, that while the profession at large prizes the *Journal*, it places relatively less than half as much value upon membership in the association. This fact becomes strikingly significant when

it is remembered that membership can be acquired by those who are eligible at no additional expense and with but trifling inconvenience. Does the *Journal* fulfill all the wants of the profession arising in connection with the association? Are there no additional advantages to be derived from membership? Is there a lack of *esprit du corps*—a lack of the sense of unity in the profession? Is the existing basis of our national organization distasteful to the majority of the practitioners? Do our subscribers embrace a considerable number of practitioners who, under existing rules, cannot become members, and whose influence, therefore, cannot be secured in behalf of the association? These are questions that I am at liberty to ask, and that you are at liberty to answer.

Another thought suggested by the report relates to the disposition of the accumulating surplus. Shall the present policy for creating a fund for the purchase of property be carried out? Shall a larger proportion of the money be expended in still further exploiting the *Journal*? Shall the members receive a direct advantage from the earnings of the property which they have created, by reducing the annual dues, or shall a certain proportion of our surplus be expended in conducting original scientific investigations on subjects of universal interest to the profession? I cannot resist the temptation in this connection to venture replies to these questions far enough to say that, in my opinion, a reserve should be held in hand large enough to meet any possible contingencies that might occur by fire or other disaster in connection with the *Journal*; that the present generous policy in promoting the welfare of the *Journal* should be continued; that the dues of the association should not be decreased; and that the question of establishing and defraying the expenses of certain commissions for special scientific investigators should be taken under serious consideration. The question of tuberculosis is not yet a closed chapter. The causation of cancer is yet a sealed mystery. The problems of tenement-house reform are not yet solved. The prevalence of various endemic diseases has not yet been made practicable. The systematic investigation of the American medicinal flora, begun under the auspices of this association more than forty years ago, remains an uncompleted task. These are a few among the many objects of a specific character which demand and should receive the fostering care of the association.

I feel, however, that, at the present moment, and under the existing features of our organization, it would be almost impossible to determine, judiciously, either of these very important questions, and I now bring them before the association only for the purpose of directing attention to them, with the hope that they may be taken up subsequently and under more auspicious circumstances.

SCIENTIFIC WORK OF THE ASSOCIATION.

The association began its career with general meetings devoted chiefly to questions of medical education and

professional conduct, and to lengthy reports from various standing committees. In 1860 it divided itself into a few sections, each with a certain autonomy, and each devoted to a particular part of our great scientific work. This change was followed by the establishment of the judicial council, by which means controversial questions, many of them of a personal character, were eliminated from the general meetings. The subsequent creation of the executive committee still further relieved the general meetings of annoying details. Thus relieved, both the general meetings and the sections have grown in scientific importance, emphasizing the persistence of our devotion to what must ever be recognized as the essential, fundamental object of our organization—the cultivation of the medical sciences. It must be acknowledged, however, that great as has been the progress in this particular, too much of the time of our general sessions is yet devoted to the consideration of matters which might, with propriety, be relegated for final action to a smaller body. It would redound largely to the interest of our annual session if the general membership could be entertained and instructed at our general meetings by exercises of a more purely scientific character, of such broad nature that they should not be restricted to any of the sections. A reform in this particular will be a long step in the direction of progress. The sections, in consequence of the faithful labors of their officers, offer strikingly attractive programmes for the present session. In several of the lists will be found the names of invited guests who, through fortuitous circumstances, are not members of the association, but who are, nevertheless, active workers in the scientific field, and whose participation in our labors will enrich the value of our proceedings and enhance the felicities of the occasion. I bespeak for them your cordial welcome. While the officers of sections and your president have exercised the prerogative of inviting guests, who come as guests, and not as members of any class as specified by the constitution, such invitations have been extended solely with the object of advancing the interests of the association. I look upon this privilege, which has been exercised by all of my predecessors and by previous officers of sections, as one of extreme importance, and one which should be continued under any plan of reorganization which may be adopted. It is my conviction, however, that the privilege should be hedged about by certain limitations, one of the most important of which should be that an invitation should not be extended a second time to any person residing within the United States whose professional qualifications may entitle him to membership. With reference to the invitation of persons identified with the allied sciences, the matter should be left absolutely to the discretion of the president of the association and with the officers of sections.

CONGRESSIONAL AND STATE LEGISLATIVE AFFAIRS.

The American Medical Association, during the first fifty years of its existence, exerted relatively little influ-

ence upon legislation, either state or national. Since the standing committee on national legislation and the national legislative council of delegates from the State societies have been established, and have become cooperative, there is some evidence that the voice of the profession is heeded at Washington. The experience of the splendid committee of this association, acting in concert with the national legislative council during the last year, has, however, shown the serious necessity for more thorough organization in protecting the interests of the profession and the interests of society as represented through the profession. The inefficiency of our present organization for influence upon Congress was shown in the inability of your committee, notwithstanding its strong *personnel* and the influences at its command, to prevent the degradation of the army medical service. This was accomplished by the passage of a bill under the championship of Senator Hawley, by the terms of which the medical corps of the army is subjected to unfair and humiliating discrimination. This law grades the medical department for rank, promotion, and, in consequence, for pay, below every other department and special corps of the army, and, with the exception of second lieutenants, it is graded below the line. In accordance with its provisions, a medical officer, to obtain a colonelcy, must pass through three times as many files as an officer of either the quartermaster's, the subsistence, or the pay departments; more than twice as many as an officer of engineers or of ordnance, and nearly twice as many as an officer of the signal corps. The effect of this discrimination is not only to lower the rank and pay of medical officers, but must result in lessening the efficiency of the corps by repelling men of spirit and worth.

In every war known to history the deaths from preventable diseases have exceeded those due to battle. At no time has hygienic science been so resourceful as at present in preventing disease. A law which fails to give to armies, either in peace or in war, the fullest protection by the application of the latest scientific developments at the hands of specially trained medical men is unjust to the soldier, to society, and to the medical profession. In view of these facts, the army reorganization law of the last Congress was inexplicable and inexcusable. It, however, forces itself upon your consideration from another standpoint. Physicians are citizens of the Republic. As such they are intellectually, socially, politically and officially the equals of any other element of the body politic. There is no station to which they may not attain; there is no distinction of which they may not be the recipients. Their rights are of manhood origin and their prerogatives are inherent. They are, in very fact, peers of the realm, and the peers of any peers of any realm. When the status of any number of physicians in their representative relationship to society is lowered, the status of the medical profession in general is menaced in corresponding degree. When the Congress, by the enactment of a law, degrades, relatively, the status of an important body of

medical men, engaged in the public service, it strikes at the status of every physician in the country. It becomes, therefore, the duty of every member of the medical profession, jealous of his rights, his prerogatives, and the fair name he may leave his children, to resent as personal between himself and every member of the Congress who voted for this law, the action which cast a stigma upon our profession.

It has been the conviction of many enlightened members of the medical profession that the means employed by the general government for the protection and promotion of the public health are capable of improvement. These duties have devolved upon the Marine-Hospital Service, which was originally designed to give succor to unfortunate people, without other domicile, who were employed upon our rivers, lakes, and the high seas. With the growth of sanitary science this service, being the only established agency available by the Government for this purpose, has been largely diverted from its original object. As a result, under the present wise administration of its surgeon-general, its representatives are abroad investigating the sanitary condition of foreign cities, its agents are at our ports beating back threatened epidemics, while valuable investigations are being conducted in its laboratories. In the exercise of its quarantine functions, however, it comes in conflict with the police power that is guaranteed by the constitution to the different States. The friction thus engendered has been especially marked in the seaboard States. While this is true, the Marine-Hospital Service, in scope and design, does not fulfill in highest degree the objects of a central coordinating agency for the protection of the public health. It was thought to create a department of public health, with its executive officer in the cabinet, but this idea yielded to that of a bureau in charge of a large advisory council, composed of representatives from the various States. Resolutions have been adopted and memorials have been sent to the Congress, committees have been appointed, money has been appropriated by this association; bills have been introduced, and hearings have been had in committee, with the result that the conditions today are precisely the same that they were ten years ago, when the agitation was inaugurated in the session of this association held at Washington.

Secretary Wilson, of the Department of Agriculture, in his report for 1899, recommended that the Congress appropriate money to defray the expense of a systematic investigation of the medicinal flora of the United States, and of experiments upon the neutralization of medicinal plants indigenous to other countries. This recommendation was based upon the fact that the United States is the only great country which either has not conducted, or is not conducting, such experiments, and upon the fact that the proposed measure, touching the avenues of industry, manufacture, commerce, and the public health, was one of national concern. This measure, however, with its

manifest importance, was denied even courteous consideration, while its friends were denied a hearing by the committees of the Congress.

The cause of failure on the part of this association to procure legislation by the Congress—and with the exception of preventing the passage of the anti-vivisection bill last year and securing the enactment of the quarantine bill this year, our recent efforts must be recognized as failures—I say the causes of our failure are properly subjects for careful consideration. I have examined the records of the association from the date of its organization, and have been profoundly impressed with the fact that memorials, resolutions, or even more definite propositions addressed to the Congress have, for the most part, represented the views, or rather the impressions, of the individual members proposing them. They have generally been presented in the general meeting, and have been endorsed without the deliberation essential for wise action; but a deliberation which is simply impossible in the limited time available in our general meetings. In certain instances memorials to the Congress have been presented at one session of the association, have been referred to committees and reported back for action, either at a later meeting of the same session or at the succeeding annual session of the association. But it becomes evident that this course lessens the evil but a trifle, for the reason that the committees to which such matters were referred have been constituted either under the leadership of the member proposing the measure or of members of a standing committee who had no interest in or understanding of the proposed measure. Such memorials, resolutions, or propositions, when acted upon affirmatively by the general meeting of the association, have, possibly, been mailed to some member of a congress or of a legislature, but have not been followed by effective work in the rank and file of the profession or among their patrons. When such bills have been presented to the Congress, and have received a certain amount of support from representatives of this association, they have, as a rule, attained only that degree of importance that has made them valuable to their ostensible champions, as something to trade in the game and barter of legislation for something which would please a larger number of constituents and command a larger number of votes. In view of the fact that, after all, the argument of votes is the only one which appeals effectively to the average congressman, it behooves this association, in its efforts to conserve the interests of the profession and of society, to put itself in position to influence the largest number of votes. Every physician, therefore, should, in a perfectly respectable sense, become an active working politician. This subject, however, is of such breadth and of such depth that it may be well for us to pause at this juncture long enough to consider, from the standpoint of fundamental facts, the relationship of physicians to each other, and of the medical profession to the aggregate as an integral factor in society.

THE PROFESSION, THE ASSOCIATION, AND THE COMMON-WEALTH.

In approaching a study, however brief, of the relation of the medical profession to the State, or, as I prefer to call it, the commonwealth, I feel that I am inviting your attention to an eminently practical theme; one which may enable us to understand the influences by which we have arrived at our present estate, and the means by which we may advance to even greater achievements. As we approach this theme—this eminently practical theme—we discover that the status of the medical profession, like that of every other element of that complex whole which we call society, is a perfectly natural one. Whatever it may be, it has been attained in the process of evolution, and has been and is determined by laws as immutable as those which govern the commingling of atoms or the sidereal strides of the planets. It is not the result of conventions or of resolutions or of statutory enactments; but these are to be interpreted rather as *indicia*, for the time being, of the position of the profession in the body politic. They are, indeed, consequences rather than causes, and as such they are subjects for careful inquiry. It is by a study of them that we are enabled in part to determine those laws, those natural laws, our harmony with which is essential, not alone for the present usefulness and continued progress of the profession, but for the ability of the medical profession to conserve the welfare and promote the happiness of society at large.

But I have said that the position of the medical profession is a natural one. The truth of this declaration is apparent when we go back to the beginnings of society—when we examine the evidences presented by primitive peoples. We are familiar with the classic example so frequently utilized as a starting point in the discussion of sociologic phenomena—the example of the two aborigines, one of whom makes better arrows and the other better mats than his companion, when, presently, one confines himself to arrows, the other to mats, each trading his own for the other's products. Here is an example of the beginning of what the scientists call "specialization of function in the social organism." It is an interesting process, which, based upon varying necessities and diverse aptitudes, results in multiplication of handicraft until somebody is hurt. This is a new necessity, and it is met by a new aptitude, and the possessor of that aptitude—the medicine man, our honored progenitor—steps upon the scene. His companions, appreciating his services, reward him with their arrows and mats; and he, finding the life to his liking, restricts himself to his new-found vocation—and the medical profession is established! As the necessity for his services, whether of charm or incantation, becomes more apparent, the esteem of his fellows becomes more pronounced. As events progress he is accorded certain rights, given certain prerogatives, and hedged about by certain limitations, all calculated to increase his efficiency in promoting the common welfare—

and thus is the practice of medicine regulated. He is spared from the battle that he may serve his companions, and he stays away from the chase that he may delve into the great mysteries—and thus is medical education inaugurated. He is the exponent, not only of his professional knowledge, but of at least the average intelligence of his people. He is, in short, an integral part of the primitive social fabric. As such he shares the manners, the customs, the aims, the ambitions of his companions; and he, with them, is controlled by the forces which determine the common state and the common destiny. His status is, therefore, determined by the very laws which control the growth and development of society itself. So true is this that, from the dawn of history until the present day, and in every stage of sociologic development, the civilization of a people may be infallibly determined by the intelligence, the efficiency, and the influence of its medical profession.

THE MEDICAL PROFESSION AND SOCIETY FIFTY YEARS AGO.

It would not be to our present purpose to follow the evolution of society as exemplified in any of the civilized peoples, or, as the scientists say, "distinct ethnic entities of the world," in which the present complexity has been attained by an orderly succession of events. And it would be equally unnecessary to show, what everybody knows, that the medical profession, the heritor, in common with others, of antecedent influences, has been propelled by the same forces and by equally orderly events to precisely the same standard of civilization. The lesson before us is that of the relation of the medical profession to a society, which, but a few decades ago, was the most diverse in origin and the most heterogeneous in constitution known to modern history; but a society which, at the dawn of the twentieth century, is one of the largest, richest, and most intelligent of the world, a society well amalgamated, and which by common consent of even adverse critics is moving in harmony with the most advanced influences of civilization. I fancy I should suddenly find myself unpopular with the audience if I were to intimate that you, who comprise it—that you, the representatives of the medical profession—have failed to contribute your full quota to the great progress which that society in general has achieved, or that you do not reflect in intelligence and morality the highest type of civilized man. I hasten to allay your apprehension, for I have no such intention. On the contrary, I ask you to indulge with me in a retrospect of American society during the last half dozen decades that we may the better understand the important part that you, and the profession that you represent, have played in the attainment of present results.

As I have already stated, the middle of the nineteenth century found diverse conditions of society in the United States. The older cities of the seaboard were the centres of an advanced civilization. The remoter counties of the same States, however, were then, in the absence of rail-

roads, the telegraph, and modern mail facilities, more remote from the centres of American influence than is St. Paul to-day from St. Petersburg. The great tide of emigration that had already poured and was yet pouring over the mountains and spreading in lonely habitations or widely separated communities over the vast valley of the Mississippi from the lakes to the Gulf, was busily engaged with the serious problem of existence. The forest was to be felled and the prairie was to be subjugated, habitations were to be built and crops were to be raised. In the midst of these exactions, institutions of higher learning were established, and to an extent patronized, and some strong men were produced. But it must be recognized as true that society in general had but little time and less money to devote either to schooling or to the amenities of life. The medical profession, under these circumstances, was precisely like the community of which it was a part. There were but few medical colleges, and they, for the most part, were but meagrely equipped. Many doctors became such while going from one town to another. Ignorant inventors of alleged systems of cure hawked their wares in the highways and the byways. Dogmatism that was destructive to intelligence was rampant, while schism was fostered by the baneful commercialism that too generally pervaded the heterogeneous mass of forty thousand people that comprised the medical profession. In eight of the twenty-six then existing States no laws affecting medical practice had ever been enacted; in eleven, laws previously enacted had been repealed; in three only were there any restrictive laws, and these proved inefficient; while the facts could not be ascertained relative to the remaining four States.

THE ERA OF ATTEMPTED VOLUNTARY REGULATION OF MEDICAL PRACTICE.

To remedy these evils, and actuated by the love of science, the promptings of self-interest, and by devotion to the interests of humanity, representatives of the various State medical societies met in convention over half a century ago and organized the American Medical Association, with the avowed object of having its members represent and take cognizance of "the common interests of the medical profession in every part of the United States." It sought to cultivate medical knowledge among its members, to elevate the standard of medical education, to promote the honor and influence and interests of the medical profession and to enlighten the public concerning the relation between the medical profession and society. Emulation and concert of action in the profession and friendly intercourse among those engaged in it were additional aims of the founders of this great body of representative American medical practitioners. A constitution, by-laws, and certain rules of conduct were adopted. The constitution provided for a delegate body, delegates being accredited from recognized medical societies, medical schools, and eleemosynary institutions. The rules of

conduct prescribed in detail the deportment of a physician, the deportment of the patient, interdicted the licensure of sectarian physicians, and proscribed from consultation those whose practice was based upon an exclusive dogma. The influence of the new association was extended chiefly through the avenues of the various State societies, many of which adopted the rules of conduct that had been prescribed by the newly formed national body as the basis of affiliation. Several of the State societies, notably those of Massachusetts, Rhode Island and Mississippi, finding either that the prescribed rules of conduct were not suitable to their respective local conditions, or feeling that they were sufficiently in touch with the ordinary forces of civilization to require no such formulæ, never adopted the rules of conduct prescribed by the national body. The Medical Association of Alabama adopted the rules with rather a naive proviso that somebody be appointed to call attention to such of the special teachings of these rules "as may seem to require elucidation in view of special circumstances and conditions." Other State societies adopted more or less modifying resolutions, but the general spirit of ostracism and aloofness was maintained during the succeeding three decades. The result of this movement was immediately salutary; it developed an *esprit du corps* in the great body of the profession; it gave an authoritative definition to medical education, and it created a strong and influential national body within the profession. At the same time, however, it became apparent that the organization did not possess the necessary inherent strength to accomplish its avowed object to regulate the practice of medicine. As time passed schismatic medicine grew apace, its colleges multiplied, its practitioners appeared all over the country exemplifying that law that always makes the blood of the martyrs the seed of the Church. Quackery of the most flagrant character was found everywhere, and society was unprotected from its ravages, while the inability of a voluntary unchartered organization to enact and to execute plenary laws was reduced to a demonstration. The medical profession, as an organized body, discovered that its relation to the commonwealth was, as the result of its own proscriptive policy, scarcely more intimate or more influential than at the beginning of the thirty years' hopeless experiment.

THE ERA OF EFFECTIVE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.

The era of effective legislative control of medical practice came as the natural reaction from the demonstrated failure to accomplish the same result through voluntary organization; but it came as the result of the sentiment which had been propagated largely through the influence of this association. The representatives of progressive medicine, turning from the national association, invoked the aid of their respective State societies in taking up the question with their respective legislatures.

The profession in each State, however, recognizing its own local conditions, proceeded in its own way to attend to its own business. The very earliest attempts to secure State legislation revealed the fact that the so-called irregular practitioners, under the stimulus of ostracism and the fostering care of public sympathy thereby induced, had become so numerous and so influential that in the majority of States nothing could be done without their cooperation. It was no longer a theory, but a condition, with which the real reformers were confronted—and they met it. California, in 1876, through its regular medical society, took the initiative. After conferences with the representatives of the sectarian societies, and after securing their cooperation, a law was procured creating a licensing board composed of representatives of both the regular and sectarian schools of practice. Illinois, confronted by precisely the same condition, took precisely the same course. Alabama, always progressive, but the happy possessor of other conditions, was able to place the regulation of medical practice for the time being under the control of its incomparable State Medical Association. Colorado created a mixed board. New York, confronted by conditions even more complicated than those in other States, took up the same task. The profession of that State, acting through its organized body, containing among its members many of the most honored and illustrious names in American medicine, found it doubly necessary to enter into treaty with the denominational physicians. It realized, however, that the rules of conduct to which it had always conformed contained, among other provisions, one which made it unlawful to “. . . examine or sign diplomas or certificates of proficiency for, or otherwise be especially concerned with the graduation of persons whom they have good reason to believe intend to support and practise any exclusive and irregular system of medicine.”

As the thing expressly interdicted by this rule was the very thing which it was proposed to do, and which had been done in other States, and which it was very necessary to do in New York, the medical society of that State amended the rules of conduct so that it or its members might, at discretion, enter into professional relations with any or all persons whom the law of the State at that time recognized to be practitioners of medicine. When this action was brought to the attention of this national body it resulted, not as might have been expected, in the amendment or the abrogation of the rule which had grown obsolete in the march of events, but in its tacit reaffirmation and in the opprobrious excommunication, for the time being, of the entire profession of the great Empire State. This action, viewed impartially after the lapse of nearly twenty years, becomes the more extraordinary when it is observed that similar action was never taken with regard to Massachusetts or Rhode Island or Mississippi, the societies of neither of which had ever adopted the prescribed rules of conduct; nor with regard to California or Illinois or Colorado, each of which had,

by overt act, if not by open declaration, so far as this rule is concerned, taken an equally non-conformist position. It is not surprising that, with such an example before the State societies, the experiment in consistency has not been repeated. But the movement of effective regulative legislation, once inaugurated, happily spread with great rapidity. Mixed boards of licensure are now to be found in the majority of the States of the Union, and in the majority of such boards are to be found members of the American Medical Association engaged in issuing licenses to practitioners of exclusive dogmas, and sitting in consultation with sectarian physicians, not over a dose of medicine, but over the vastly more vital question of the qualifications of those who are to care for the sick of our Republic.

THE MEDICAL PROFESSION AND SOCIETY AT THE BEGINNING OF THE TWENTIETH CENTURY.

The results of the twenty-five years of statutory regulation of medical practice are in striking contrast with the results of the quarter of a century of attempted regulation by methods of proscription. At the conclusion of that humiliating experiment, as at the beginning of it, there was not a single effective medical practice law on the statute books of a single State of the Union. To-day there are forty-eight State or Territorial licensing boards, the most of them being composed of representatives of both the regular and the sectarian schools of practice. The laws of the different States are of varying efficiency, the one procured by the Medical Society of the State of New York, at the price of yet-maintained excommunication from this body, standing to-day as the model of excellence for the entire country. Under the influence of these laws, instigated by members of the American Medical Association, and which, after all, are but expressions of the sentiments of the medical profession confirmed by society at large, many substantial reforms have been accomplished. The medical schools which, in this country, have labored bravely and efficiently under adverse conditions, have been stimulated to increased efficiency. One of the first changes accomplished was the practical standardization of requirements to enter practice; and one of the first features of this standardization was to secure for the student “the aids actually furnished by anatomy, physiology, pathology, and organic chemistry”—the four cardinal studies which, strange-sounding as it seems, it was necessary solemnly and specifically to insist upon a half century ago. It follows, therefore, that with broadened and increasingly uniform curricula, it cannot be said that schools even of sectarian antecedents entirely “reject the accumulated experience of the profession,” nor can it be said that, in a sectarian sense, they any longer possess an excuse for existence. Their graduates, or such of them as do not base practice on an exclusive dogma, are, in many instances, met in formal consultation by even conservative regular physicians, and, in more

than one instance, are made members of medical societies that are in affiliation with the American Medical Association.

The Illinois State Medical Society, which has always been among the foremost in reform movements within the profession, at its recent annual session, unanimously "Resolved, That the school of graduation shall be no bar to membership in the Illinois State Medical Society, providing such physician is recognized by the local societies as qualified and not claiming to practise any exclusive system of medicine."

The Ohio State Medical Society, by precedent, if not by formal action, established the same rule.

We thus see that the proscriptive rule which, during the more than twenty-five years of its dominance, propagated the very evils it was intended to correct, is rapidly expiring by limitation in the face of new conditions that have been induced, in spite of it, by beneficent and catholic legislation. In the State of New York alone the annual registration of sectarian physicians has diminished nearly ninety per cent. under the operation of its present laws. In the State of Ohio many physicians who are graduates of sectarian schools are making application to have their classification on the register changed to "regular," while equal reactionary movements are observable in other States. Thus we observe the passing of Homœopathy and Eclecticisim just as did the calm scientists of Rome witness the passing of the "Humoralism," the "Methodism," the "Electricism," and the "Pneumatic School" of that period; and just as passed the "Chemicalism," the "Iatro-physical School," the "Iatro-chemical School," and the "Brunonianism" and the dozen other "isms" of later epochs, each leaving its little modicum of truth as the memento of its existence. And let us felicitate ourselves that, with the passing of the particular sectarianism of the last century, there is also the passing of its concomitant evils, such as existed in even greater degree in the time of Galen, who "found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems," and, as if relating the effect of the cause, the historian continues, "the social status and the moral integrity of the physician degraded." The further results of this new order of things, however, are observable, not alone in the modified curricula of the medical schools, but in the changed organic relations of the institutions themselves. Under the pressure of legal requirements the weight falls with almost fatal force upon the small, private and poorly equipped institutions. These institutions, in the interest of self-preservation, and to protect respectable alumni, are forced either to expand their enterprises or to seek relations with universities which are deeply founded in the community; or else actually to go out of existence. The majority of the schools seek connection with the universities, by which step alone they become logical objects for endowment, and it is to be hoped that this movement will continue until in this great

country medical education shall be as firmly established as it is to-day in any of the transatlantic nations.

Another of the new conditions which has developed within the last quarter of a century, as the result of an increasing professional unity, is the efficient sanitary regulations, national, state and municipal, that now afford protection to the people from diseases that were formerly devastating in their effects. It is not necessary in this audience to mention small-pox, cholera, typhoid fever, diphtheria, anthrax, leprosy, and the bubonic plague, each of which has been brought under relatively effective control, but I do feel that it is necessary to emphasize the fact that there are many unsolved problems relating to the prevention of disease that stand as a challenge to the industry, the ingenuity, and the courage of the profession. While these various changes have taken place, others of almost equal importance are observable in the relations of physicians to society. While the community, instigated by the medical profession, has given to that profession a legal status, definite and increasingly influential, and has given it certain prerogatives and certain exemptions, it has, likewise, hedged it about with certain limitations and imposed upon it certain liabilities. There are numerous laws, both common and statutory—*lex non scripta* and *lex scripta*—that admonish the physician that his conduct carries with it a liability not defined by self-imposed rules, and the numerous courts of our land proclaim that there are tribunals "other than his own conscience to adjudge penalties for carelessness or neglect" on the part of the physician. So numerous, so unjust, and so disastrous are actions before such tribunals that they have caused the development of a new, legitimate and beneficent enterprise, in the development of a company to insure physicians against malpractice. It may be true that in certain States and localities these laws are unjust, and that there is a grave error in their administration by judges created under our wretched elective system; but if so, the facts only emphasize anew the necessity for more complete organization of the profession and for the more active exertion of its influence upon elections.

THE REORGANIZATION OF THE ASSOCIATION.

This brings us again to a realization of the fact that the results that can be achieved only by the unification of our national profession cannot be attained under the present organization of our association. The disproportionately rapid growth of the *Journal* as compared with that of the association can have no other significance. The weakness of the committee on legislation, at Washington, was a question neither of personnel or of industry, but arose purely from the fact that there was no efficient organization in the rank and file of the profession by which speedy and effective influence could be brought to bear upon members and senators. Equal difficulty has been encountered in several States where organization has

been similarly defective. The demand for more effective organization of the association has come from all over the country and resulted in the adoption of a motion at Atlantic City authorizing the appointment of a committee of three to report a plan of reorganization at this session. Another motion was adopted authorizing the creation of a supplementary committee of one from each State and Territory, entitled a committee on organization, which has been filled by appointing for the most part the retiring presidents of State societies for the current year. The committee on reorganization, consisting of Dr. J. N. McCormack, of Kentucky, Dr. George H. Simmons, of Illinois, and Dr. P. Maxwell Foshay, of Ohio, has given to the important question entrusted to it a most careful and painstaking consideration. It has laid before you the results of its deliberation. In doing so it has emphasized the principle that this association has its origin in the organized profession of the respective States. It emphasizes the fact that the delegate body should be so small that it can remain in prolonged session and give to the various subjects under consideration that deliberate attention which has not been possible under the existing scheme of organization during the last forty years. It recognizes the paramount importance of the scientific feature of our work by relieving the general meetings and the sections alike of the troublesome details that now consume the limited and valuable time of the sessions. It remedies the glaring and serious defects in the present constitution. It prepares the association, by perfecting the organization, to meet important and pressing questions. These considerations, together with the fact that the existing constitutional provision relative to delay of action on pending amendments has been met by the appointment, a year ago, of a committee for the avowed and published purpose of reorganization, and by the action of the committee in laying the results of its work before every member of the association—I say these considerations and these facts prompt me to advise the adoption of the proposed constitution and by-laws in their entirety at the present annual session of the association.

The committee on reorganization, under the restrictions of the resolution creating it, has, very properly, left undisturbed the existing rules of conduct. These, if construed to have a fundamental importance, and if vigorously enforced as they now stand, would disintegrate the association in a single day. This reason, and others already given, confirm me in the conviction that such rules should be either amended or abrogated, or, if reaffirmed, it should be by general resolution endorsing their underlying principles but disclaiming the present applicability of their details. There are, however, various views entertained upon this subject, and that the matter may be approached in a spirit of tolerance, that it may be discussed coolly and impartially, that a consensus may be reached, and that harmony may be attained, I recommend that the general questions of the revision of

the rules of conduct be referred to a special committee on ethics, consisting of three members, with instructions to report to the legislative body at the next annual session of the association.

THE NEW SCHOOL OF MEDICINE.

The changes which I have advocated are essential for the attainment of the purposes of the association and for the fulfillment of the high destiny of our national profession. They are demanded by the changes that have taken place during the last fifty years. The legislative functions have passed from voluntary organizations to the Congress and the legislatures, where they belong; but it still devolves upon the profession in the organized capacity, to stimulate, to restrain, or otherwise to control the law-making power. The responsibility of the profession is increased, rather than diminished. Science has come to have a clearer meaning. He who now proclaims a dogma cries alone in the night, while the world sleeps. They who demand a creed may read its varying terms only in the progressive revelation of natural laws. Practice has changed. The depletions, the gross medications, the absurd attenuations, the ridiculous anti-mineralism have given away to a refined pharmacy and to a more rational therapy. Sacrificial surgery has yielded to the spirit of conservatism. Prevention is given precedence over cure. Education implies research and discovery, and all may delve. I proclaim, events proclaim, the existence of a new school of medicine. It is as distinct from the schools of fifty years ago as is the Christian dispensation from its Pagan antecedents. It is the product of convergent influences, of diverse antecedent origin. It acknowledges no distinctive title, it heralds no shibboleth. It is a school of human tolerance, of personal independence, of scientific honesty. It is the slave of neither prejudice nor preconception, and abandons the accepted truth of yesterday, if only it be the demonstrated error of to-day. It places no premium upon personal prerogative, and extends no recognition to individual authority. It makes no proclamation of completeness, no pretension to sufficiency. It recognizes that truth is undergoing progressive revelation, not ending to-day, but continuing through the ages. It yields its plaudits to achievement, and recognizes that he is the greatest among men who reveals the most of truth unto men. It greets as a friend him who thinks, though he think error, for, thinking, he may think truth and thereby add to the common fund. It heeds all things, examines all things, judges all things.

To you, the exponents of this new school, of this new generation, of this new century; to you, representatives of the Democracy of Science; to you, citizens of the Republic of Letters, I extend greetings; and here, in our parliament assembled, here, where our will is supreme, I this day invoke upon our deliberations the spirit of liberty, the spirit of courage, the spirit of progress, the spirit of truth.

INTERNAL MEDICINE IN THE NINETEENTH CENTURY.

BEING THE ORATION IN MEDICINE BEFORE THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ST. PAUL
JUNE 4, 5, 6, AND 7, 1901.

By N. S. DAVIS, JR., M. D.,

CHICAGO.

IT is one of the duties of those who address you, as I do to-day, to review what has been newly discovered in the field of medicine or in some limited department of it. At this first meeting of the American Medical Association in the twentieth century, it seems most natural to review what has been accomplished in the last one hundred years. The time at my disposal is too brief to read to you a complete history of the achievements of this wonderful epoch, for more of genuine advancement has been made in medicine during it than during all the preceding centuries together. It is only possible for me to point out some of the reasons for the rapid development of medicine, to recall to your minds some of the most important discoveries and applications of them.

A century is not so long a time as we are apt to think. Our grandfathers were vigorous men, in the prime of life, when the nineteenth century was born. Yet changes so great that they seem miraculous have occurred since then. In 1800 this great country was a wilderness, unknown even to the inhabitants of the few straggling settlements upon the Atlantic coast. Our land contained no great cities. There was little travel from place to place. There were no steamboats nor railways; no telegraphs or telephones. Information traveled slowly by packet ship, canal boat, and stage coach. The discovery of the wonderful properties of the x ray could not then have been flashed over the world in a day and its genuineness and utility confirmed within a few weeks by experiments made simultaneously in all parts of the world, as did happen at the close of the century. To-day all civilized peoples are so united that knowledge has become the common property of them all. In former epochs geniuses delved alone, inspired only by their own enthusiasm. Often, it was many years before their discoveries became widely known or appreciated; and many more before another genius standing upon land already found ventured upon its exploration.

All this has been changed. Learning is not possessed by a few, but by many. In earlier epochs men of genius towered above their contemporaries in learning. To-day thousands crowd about their shoulders, so much higher is the average of learning. All scientific workers are now linked together by the rapid dissemination of news, so that no matter in what part of the world they may be, they are kept conversant with what is being thought and done in every other part, and they are thereby inspired to greater mental efforts.

Knowledge is no longer isolated. It is cultivated in centres too numerous to count. Even in this new land

universities with great libraries, finely equipped laboratories, and corps of brilliant teachers and seekers after new knowledge are found in every part of it. Medical societies have been organized in every state and city, and in many counties and towns. But at the beginning of the century there were only four medical schools in this country, and four state societies, organized for the advancement of medical knowledge.*

These changes have been effected chiefly by the rapidity of communication which has been established in all civilized lands and by the greater concentration of the people in large cities.

But it is not in the United States only that the population has increased and concentrated. In 1801 the total population of England and Wales was less than 9,000,000. Of this number more than half lived in the country. At the end of the nineteenth century the population of the same countries was more than 29,000,000, and only one fifth of this number lived in the rural districts. These figures attract our attention to the social changes which have occurred in all civilized lands—changes which have not only effected a greater diffusion of knowledge but have also modified the conditions which produce and limit disease.

At the opening of the nineteenth century, Cullen's *Practice of Physic*, written late in the preceding century, was the standard text-book. A glance at its contents will give us the clearest conception of the state of medical knowledge at that time. In an edition of this work, printed in New York city in 1806, I find no description of structural diseases of the heart; even as a complication of rheumatism heart disease is not mentioned. A single page is devoted to nephritis, but in its description there is no mention of the chemical and microscopical changes in the urine upon which we depend to recognize it and to distinguish its forms. The affections of the respiratory organs were described with similar crudeness, under such chapter headings as Of Catarrh, Asthma, Pneumonic Inflammation, Peripneumonia Notha, and Phthisis Pulmonalis, but the catarrhal inflammations of the nose, pharynx, trachea, and bronchi were not differentiated from one another, nor were catarrhal and croupous pneumonia, brown induration, hypostatic congestion and œdema of the lungs described.

The hypothetical explanation of diseases and their causes which prevailed at that time is well illustrated by the conclusion reached by Noah Webster, who, in his *History of Epidemics and Pestilential Diseases*, writes that typhus and nervous fever are due to "conversion of the perspirable fluids of the body into septic matter."

Nothing will help so much to make clear the progress made in medicine in the last century as to compare the resources at the disposal of physicians of our day with those commanded by our grandparents. At the opening of the nineteenth century medical men knew nothing of

*The colleges were medical departments of Pennsylvania, Columbia, Harvard, and Dartmouth (founded 1797). The societies were New Jersey (1766), Massachusetts (1781), Connecticut and New Hampshire (1791).

the clinical thermometer, of percussion, auscultation, uranalysis, clinical microscopy, laryngoscopy, ophthalmoscopy, of the sphygmograph, or Röntgen rays.

It was not until the year 1803 that Corvisart spread widely a knowledge of percussion as a means of discovering the physical status of the viscera, although the work of Avenbrugger, which he translated, and which was the original description of percussion, had been published nearly fifty years before. The work of Avenbrugger and Corvisart was supplemented in 1819, when Laennec published the result of his labor with the stethoscope, which he had invented four years earlier. From this time dates our clinical knowledge of diseases of the lungs and heart.

In 1827 Bright pointed out the relationship of albuminuria, dropsy, and diseases of the kidneys. At this point clinical chemistry may be said to begin.

At the beginning of the nineteenth century compound microscopes were almost useless, for the images which their lenses made were so distorted and colored that they could not be properly interpreted. In 1812 Dr. William Hyde Wollaston combined two plano-convex lenses so as to correct the spherical aberration which a single double-convex lens produces; and nearly twenty years later Joseph Jackson Lister discovered the utility of combining lenses of crown and flint glass in order to produce an image in the microscope relatively free from distortions and fringes of color. The more recent invention of the oil immersion lens has made bacteriology possible and has solved many of the problems of infectious diseases which puzzled even our fathers in the fifties and sixties.

The dependence of medicine upon ancillary sciences is well illustrated by the sudden birth and rapid development of new branches of medical knowledge which are dependent on the perfection of the microscope.

This instrument has made histology, embryology, modern pathology, and bacteriology a possibility. These departments of science are altogether products of the last century.

It was at the beginning of the century that Bichat divided the structures of the body into what he called "tissues" and showed that there were only a few of them. It is surprising that the great anatomists before him did not make the same discovery.

As modern anatomy has been dependent upon the microscope in order to explain structures, so physiology has been dependent upon experiments on living animals to explain function. It is true that in earlier epochs, at considerable intervals of time, experiments upon living animals were made, notably by Harvey, when he studied the circulation of the blood, but they were never made systematically until the discovery of anæsthesia in the nineteenth century made them painless. No wonder, therefore, that the explanations made by physiologists in 1800 seem to us extremely crude. Haller, for instance, whose printed lectures formed the text-book of most students at that time, thus describes the nature of blood:

"Hydrostatical experiments demonstrate in the blood first a kind of volatile vapor or exhalation which immediately and continually flies off from the warm juice with a sort of foetid odor coming betwixt that of sweat and urin. This vapor, being caught and condensed in proper vessels, appears of a watery nature joined with a small tincture of an alkaline disposition."

A few pages further on, what he says of the blood gives us an idea both of the state of physiological and pathological knowledge at that time: "For the blood in a sound healthy state, not injured by putrefaction or too violent a degree of heat, is neither alkaline nor acid, but mild and gelatinous and a little saltish to the taste; yet in some diseases it is sharp enough and comes near to a state of putrefaction, as for instance in the scurvy, when it corrodes through its containing vessels and in those who have ascites or dropsy whose waters are often much of an alkaline and corroding nature."

At the close of the eighteenth century the part which gland cells play in forming secretions was not comprehended. It was believed that "the albuminous or hardening juices are separated almost anywhere from the arteries themselves, into continuous excretory canals, with any intermediate organ or machine betwixt them." It was believed that all excretions existed primarily in the blood.

The physiologists of this period appreciated the importance of the lungs and the act of respiration, but their exact use they did not comprehend. Haller enumerates several possible functions which they might perform, yet he did not feel sure that any one of them was the real one. For instance, he says: "Our blood acquires its heat principally in the lungs, for that all animals which have lungs and two ventricles in the heart have the heat of their blood commonly twice that of the atmosphere. But does not this arise from the alternate extension and contraction, relaxation and compression of the pulmonary vessels by which the solid parts of the blood are perpetually rubbed together and closely compressed in the attrition that is made during expiration, as it is more rapidly moved and ground together during inspiration?"

Our forefathers one hundred years ago often endeavored to hide their ignorance in long names and resounding phrases, a common practice, indeed, in all times and not wanting to-day, for how much ignorance will our successors find hidden in words now so commonly used as are metabolism and auto-intoxication.

Pathology as a distinct department of scientific medicine originated in the nineteenth century. It was not until 1860 that Rudolf Virchow demonstrated conclusively his famous dictum: "*Omnis cellula e cellula.*" His studies of cells in disease laid the foundation and did much to rear the superstructure of cellular pathology. So rapidly has a knowledge of this subject grown that we can unhesitatingly say that we now possess very accurate and detailed information as to the anatomical changes which disease effects. The insight of physicians was so

greatly extended into the nature of morbid processes by these pathologic studies that enthusiastic devotees of them felt that the application of the microscope to the study of disease would dispel its mysteries. Increasing information, however, soon demonstrated the limitations which exist as to knowledge derivable from a study of morbid anatomy. Most of us remember how, soon after the birth of bacteriology, it was also hoped that from it at least we should learn the true essence of disease. But we know now that in most ailments after the bacteriologist has discovered the offending micro-organism the chemist must help us, for it is usually a product of its growth, not its physical presence in the tissues, that causes disease.

The production of disease by parasites imbedded in the tissues of the human body was suspected from early times, but was not demonstrated until the end of the first third of the nineteenth century, when James Paget, then a medical student, found unusual nodules in the muscles of a man whom he was dissecting. These Richard Owen demonstrated to be the cocoon of a minute animal which he called *trichina spiralis*. In 1847, Dr. Joseph Leidy, of Philadelphia, found them also in pork, and soon thereafter it was shown in Germany that men could become infected by eating pork containing *trichina*, and that in consequence there developed in them a definite train of symptoms.

In 1837, Latour in France, and Schwann in Germany, almost simultaneously propounded the view that fermentation and putrefaction were due to the growth of micro-organisms. Liebig, with all the weight of his authority, antagonized this belief in a "vitalistic" explanation of these phenomena. Pasteur undertook to settle the dispute by methods of research, which proved to be the foundation of a new department of science—bacteriology. The results of his experiments were published between 1857 and 1869. He proved that without micro-organisms there could be no fermentation, no putrefaction or decay. These studies prompted many investigators to attempt to demonstrate the suspected relationship of micro-organisms to disease. In 1863 Davaine succeeded in showing that the organisms, seen by him in 1850 in the blood of animals which had died of anthrax, were its cause. This, as some of those before me will remember, aroused a storm of controversy which was not settled finally until after my own student days.

Formerly, such vague terms as "miasm," "humor," and "virus" were used to explain the communicability of contagious diseases, but they have had to be discarded or to be newly defined by the bacteriologist. It was in the sixties that Lister made his studies upon the relationship of micro-organisms to wound infection. The brilliant, revolutionary results of those studies are too well known to you to require elaboration; besides, they belong to the history of the nineteenth century surgery rather than to the history of internal medicine. They were, however,

so important in settling the relationship of invisible parasites and diseases that they must be mentioned.

It was at this time, too, that Pasteur and Tyndall finally settled the controversy over spontaneous generation which had raged from time immemorial. The world at last felt convinced that even micro-organisms could not exist where an antecedent organism had not been.

It is needless to recapitulate the long list of discoveries rapidly made from this time onward of the causes of infectious diseases, by such men as Koch, Klebs, Loeffler, Fraenkel, Laveran, and many others.

Although medical men have been incited to search for the causes of disease, in order that they might understand their nature better, and therefore be able to treat them better, such studies naturally led more directly to the prevention than to the cure of disease. That is why the recent epoch-making bacteriological discoveries have greatly stimulated the study of preventive medicine. It is true that the prevention of disease has engaged the attention of medical men and statesmen since the earliest times, but the subject was not studied systematically before the last century.

Hygiene as a separate department of medicine, with a literature of its own, was created only in the nineteenth century.

While, in the eighteenth century, much was done to improve the hygienic state of individuals, and as a result there began before its close to be a reduction in the mortality rate, which has continued up to the present time, public hygiene, or attempts to prevent the spread of disease by state and civic interference, was not fairly established until very recently. Even to-day small communities have no health officers or sanitary inspectors, and few regulations which are intended either to inform the people as to the relative healthfulness of towns and hamlets, or by which the spread of disease is to be lessened. These facts show how new and undeveloped as yet the field of public hygiene is. The mortality statistics which have been gathered in cities since the middle of the last century make it possible to point out which among them are the healthiest, and which diseases are the most destructive. It is to be hoped that these statistics in the future will be supplemented by reports of the kinds and amount of illness, whether fatal or not, that may exist in a given place.

The knowledge recently acquired of infections and their spread has already been applied to their prevention. Such diseases as erysipelas, septicæmia, and tetanus no longer torment surgeons when they can make clean wounds. But so late as 1870 the first of these ailments was common in the hospitals of France. Puerperal fever is to-day as rare as it was common formerly. Typhus fever no longer exists in America, although not uncommon at the beginning of the last century.*

*Typhus forms an item in the mortality reports of Chicago (and other American cities) so late as 1886. This is probably because it was confused with typhoid. Not during the first quarter, and rarely afterward, has genuine typhus occurred in this country.

Indeed, it is rarely seen in any civilized country to-day. At the beginning of the nineteenth century small-pox was so common that few persons reached adult life without having had the disease, and the mortality from it in childhood was great. What is the status of this disease to-day? I venture to say there are many physicians in this audience who have never seen a case, and that a majority of them have not treated more than four or five cases during their whole professional experience. In the early days of this nation's history yellow fever spread to Philadelphia and New York, and provoked much discussion, for it was feared that it would prove as great a pest as cholera. A careful study of the disease and a consideration of the possibility of preventing it was referred to a committee of the New York Medical Society, which reported that yellow fever might be produced in any country by pestilential effluvia. How different is this conclusion from that of recent students of the subject, who assign to it a specific cause that is transmitted from man to man by mosquitoes, which are its host.

Cholera has been brought to our shores several times in the last few years, but its spread has been prevented in each case. In Europe it has also been limited to comparatively small areas. Within a year the plague has been found in this country, in Great Britain, and France, but has caused little alarm, so great is the confidence that it will be successfully suppressed. (Let us hope that this confidence is not misplaced.)

What has been accomplished during the last one hundred years by internal medicine the following statistics will show in part, although it must be remembered that mortality statistics gathered before the middle of the century are not reliable. It is estimated that in 1805, in New York city, from 35 to 40 deaths occurred in every 1,000 inhabitants. During the last decade it has averaged 20 in 1,000, and has been as low as 19 in 1,000. In 1847, the mortality in London from zymotic diseases was 23.26 per cent.; during the last two decades, 19 to 20 per cent. In 1846, the deaths from consumption were 12.67 per cent.; now, approximately 9 per cent. The mortality from diseases of the respiratory organs has been reduced in the same time from more than 12 per cent. to about 7 per cent., and the mortality from diseases of the digestive organs has diminished from about 6 per cent. to less than 5 per cent. In Chicago the mortality rate has fallen, with small fluctuations, from 46 and 64 deaths per 1,000 inhabitants, in the cholera years of 1852 and 1854, to 14 in 1898. The following diseases are among those in which the death-rate has fallen progressively: Cholera infantum, croup, diarrhoea, diphtheria, dysentery, malaria, measles, scarlet fever, and whooping-cough. These are ailments the spread of which has been controlled, either by isolation, or by insuring the people purer food and water. Although the general mortality of Chicago, which is typical of the great cities of civilized countries, has improved, there are some diseases which are increasing in prevalence, notably nervous diseases, heart dis-

eases, cancer, Bright's disease, bronchitis, and pneumonia. To the discredit of my native city must it be said that the mortality from typhoid fever reached its highest point at the close of the century, during 1890, '91, and '92, although its cause and its mode of dissemination, as well as its prevention, were well known.

The general lowering of the death rate is due to the improved hygiene of communities. In what the improvement has consisted is best shown by recalling some of the conditions under which people lived in 1800. At that time few cities had an adequate public water supply. In London, water could be delivered at any house three times a week by one of the water companies; but most households depended upon wells. The sewerage system was quite as imperfect. Outhouses and cesspools were attached to each dwelling. The conveyance of sewage from houses by water did not become general until well into the last century. Ventilation of buildings, and especially of public halls, had attracted attention before the nineteenth century; but the real causes of danger from bad ventilation were not appreciated until bacteriology disclosed them.

In 1800, streets were not paved, and were rarely cleaned. The habits of the people as regarded eating and drinking were bestial. Excessively large quantities of food were consumed by all who could provide it. Alcoholic beverages were universally drunk, and generally in immoderate quantities. No disgrace attached to drunkenness; and it was customary for a man to drink several bottles of wine at a sitting.

Those who compose this audience appreciate how much illness must have been caused by these habits, and how much the relative abstemiousness or temperance of to-day has lessened the percentage of disease.

Prevention of diseases is only possible when a knowledge of their causes, their mode of dissemination, and methods for their suppression, are possessed by all the people. Medical men alone cannot stop their spread, nor will the making of laws do it. Only the intelligent cooperation of those who are ill and those who are well can accomplish it. It must not be expected, therefore, that so soon as the cause of a disease is discovered, that ailment can be suppressed. Time is required in which to educate all classes of people on that particular subject. Unfortunately, many persons are so obtuse that they will not believe in methods of prevention even when the fullest demonstration of their success has been made. A notable instance of this is seen in the recent repeal in England of laws which made vaccination compulsory. The ease with which drinking-water may become contaminated and the danger to health from contamination are not even now appreciated by the public. It is partly because such thorough knowledge is needed by the laymen that tuberculosis, diphtheria, pneumonia, typhoid fever, and similar troubles have not been better controlled in the past. In order that in the twentieth century the fruits of the great discoveries of the last may

be gathered, all members of the medical profession must fit themselves to teach their patients what is known of disease and its prevention. Those who are specially adapted to do so must disseminate their knowledge by popular discourses and essays. When hygiene shall be regarded by all classes as necessary, and as much a matter of course as the use of the railroad, steamboat, the telegraph, telephone, and labor-saving machines, then, but not until then, striking results may be expected.

The wonderful, the revolutionary discoveries made by students of internal medicine during the nineteenth century are not always appreciated as they should be, for their results are often demonstrable only by statistics; and the dramatic rescue of individuals from certain death, which the surgeon at times accomplishes, unfortunately cannot be effected by the therapist. It is not in the nature of his art. Great progress, however, has been made in the use of medicines and remedial procedures. Good reasons can be given for their employment, and their mode of action can be explained. Empiricism no longer governs their use as it formerly did. The placing of therapeutics upon a scientific basis began in the last century, when the physiological effect of drugs was first demonstrated by experiments upon animals.

No field of medical research needs cultivation so much as, or is more certain to yield a rich harvest than, therapeutics. It is surprising that we have not a larger volume of accurate knowledge of the effect of drugs than we do possess. Of late, pharmacology has been neglected for studies which have temporarily been more enticing to experimenters, such as bacteriology and experimental pathology. Moreover, a knowledge of these subjects is essential to enable a clinician to apply his therapeutic resources to the mitigation of suffering, the support of strength, and the elimination or destruction of noxious substances. One can safely prophesy that the exact utility and the limitations of drugs and medical procedures will be defined in the present century.

To accomplish this, not only is more knowledge required of the physiological action of drugs, but also better means of accurately measuring their effects when they are given to patients. We know that when pain is relieved we can sometimes measure effects produced upon the heart and blood-vessels and temperature. Beyond this, we depend for knowledge upon the impressions of physicians, impressions which must be corrected and often reversed by a wide experience. Clinicians possess only a few appliances or methods for the exact study of the sick. It is to be hoped that more will be discovered, and that they will also make it possible to register with accuracy the effect of drugs. When this is accomplished, undoubtedly a smaller number of useful drugs will be employed, but these with greater exactness.

It is true that more drugs are used to-day than need be, because patients demand them as a fetish; but this will be changed when laymen learn that it is the function of the physician to teach them what to do to give

Nature the best chance to effect repair, what to do to make themselves comfortable and to preserve life; when they learn that it is a physician's function to teach them how to protect others from the same ailment, to foretell the possibility of recovery or death, and to avert or forestall complications. Medical men should include time and faith in their materia medica as important means of effecting a restoration to health. I do not mean faith in a fetish procured in an apothecary's shop, but faith in the wisdom, honesty, and disinterested devotion of physicians, which will enable them to accomplish all that can be done for the suffering.

Although the greatest discoveries in the field of internal medicine have been applicable to the prevention of illness in the masses, much has also been done to increase the chances of recovery of individuals who are sick. I need call attention only to a few of the improvements in treatment which have been effected, to remind you of more. Typhoid fever, which has been a scourge in all civilized countries, and constantly present in all larger centres of population, has not only been greatly lessened, sometimes even suppressed, by improved hygiene, but the chances of recovery of the one who is sick with it have been increased several fold by improved methods of treatment. Twenty-five years ago the mortality from typhoid fever in the hospitals of the world was from 20 to 35 per cent.; to-day it is from 5 to 15 per cent. The better results are due to the cold baths which are used, to a more generous supply of fresh air, to proper feeding, and to protection against, or the prompt treatment of, complications.

One great therapeutic discovery has been made at the end of the nineteenth century—the discovery of antitoxines, the natural antidotes to the poisons of infectious agents. For a very long time it had been known that something developed in the human system during the course of many ailments which gave to the sufferer from them for a variable time immunity from a recurrence of the disease. Until the existence of parasites and of poisons generated by them was proved, an antitoxine was, of course, unrecognizable. Moreover, the possibility of such a thing in diseases, one attack of which did not cause immunity to others, was not even suspected. But the diphtheria antitoxine, the most efficient of those of which we know anything, is one belonging to this last group of ailments. The chemical composition of antitoxines is yet to be discovered. Since antitoxine has been used the mortality from diphtheria has been reduced about one half. The most extensive collection* of statistics gathered from all civilized countries shows that, when antitoxine is used on the first day of the disease, the mortality is 5 per cent., increasing rapidly to 30 per cent. when used on the fourth day or later. Before its employment, the average mortality of the disease was from 25 to 35 per cent. To effect a still greater reduction in the death rate from this ailment, it is necessary that it be recog-

*Das Oesterischen Sanitätswesen, No. 52, 1900.

nized early, and that antitoxine be employed more generally as a preventive for those who have been exposed.

That tetanus antitoxine and plague antitoxine are valuable is admitted. Many others, such as pneumonia, typhoid, tubercle, scarlet fever, erysipelas, and streptococcus antitoxines, are still in the experimental stage. But even though it should be found that few natural antitoxines can be isolated for use as remedies, those already discovered confirm physicians in the hope that specifics will be found some day.

Another therapeutic discovery made at the close of the century, which has thrown a flood of light upon some obscure points in physiology and pathology and has restored to usefulness many who were formerly incapacitated and incurable, is that of internal secretions, and especially the rôle of the secretion of the thyroid gland. Ingredients in the thyroid, suprarenal bodies, and ovaries produce as definite effects upon the living body as many extracts from plants or synthetic chemicals. The pituitary body, the thymus, and bone marrow may also have a value as yet undetermined. The rescue of those suffering from myxœdema and cretinism, by the administration of thyroid, is one of the few happy dramatic incidents which fall to the lot of the practitioner of medicine.

That a much larger proportion of recoveries from tuberculosis occur to-day than formerly is evident from the statistics of this disease, but this lessened mortality is not due to prevention only. Trudeau has estimated that eighteen per cent. of all persons have tuberculous lesions, because a reaction to tuberculin can be demonstrated in that proportion. This statement is confirmed by Councilman, who states that his autopsy statistics show that at least seventeen per cent. of all who die have had this disease. But, in spite of this prevalence, the mortality from the ailment is lessening.

Rabies and tetanus are two diseases which until recently were thought to be incurable. Rabies can be suppressed by killing unowned dogs and by muzzling the rest. Upon this point the following statistics from England are very instructive: In 1887, 217 deaths occurred in Great Britain from rabies; in 1888, 160; in 1889, 312. A muzzling law was then enforced. In 1891 the death rate from the disease fell to 129; in 1892, to 38. The muzzling ordinance was repealed, with the result that in 1894, 248 deaths occurred from mad-dog bites, and 672 in 1895. Again muzzling was made compulsory. The death rate once more diminished; in 1897 it was 151; in 1898, 17; in 1899, 9, and in 1900, none!

Pasteur's great discovery of a method of attenuating the virus of rabies and rendering immune those who have been bitten by mad dogs by rapidly accustoming them to stronger and stronger viruses, has reduced the mortality materially.

Tetanus, formerly quite common in hospitals, is now prevented by properly cleansing and protecting wounds.

It has become so rare a disease that to-day most students do not see a case of it during their college course.

The nineteenth century will be known in the history of medicine as the century of experimental medicine, for it is in that field that the greatest discoveries of the age have been made. The names of Pasteur, Koch, and Lister will forever be linked with it as representing its greatest achievements. But these achievements would not have been possible had not the physicist perfected the microscope, and had not Virchow and his pupils explored the field of cellular pathology to its farthest limits. Around Virchow's name as a banner will historians gather the achievements in medicine during the early and middle portions of the century, and around Pasteur's those of its close.

If our greatest needs conditioned the growth of knowledge, we could prophesy what would be the great field of research of the twentieth century, but history teaches us that our needs can often not be met until some sister science has grown, or new methods of experimenting have been devised. Therefore the future must remain a blank to us. However, we are more apt to accomplish what is needed if the problems are kept clearly in mind. We greatly need more exact methods of clinical study, more accurate knowledge of the effect of remedial agents and procedures, but more than all else we need a knowledge of the changes which take place in the living tissue in health as well as in disease.

The anatomist has resolved the cellular structure of the body; the physiologist, the laws which govern the action of its organs and the chemical changes which are wrought upon its surfaces; the bacteriologist has discovered the parasites that infest, and often destroy it; the pathologist has described the anatomical changes which disease produces; the clinician has linked all these facts together and has discovered ways of seeing with the intellectual eye disturbances of physiological function, of determining their cause, and of anticipating the anatomical changes which they will produce. But this does not satisfy us; we want a knowledge of the atomic and molecular structure of cells, of the changes which take place in the atoms and molecules in health and in disease, and of the effect of medicines and remedial procedures upon them.

This knowledge chemistry must give us. I feel sure that, standing as we do at the beginning of a new century, expecting greater developments in it than in the last one, we are halting before new discoveries in chemistry, waiting for new methods of studying metabolism in microscopic portions of tissue. When this knowledge is vouchsafed, medicine will make another stride as great as was made when, by the perfected microscope, cellular pathology and bacteriology became possible.

Let us look forward with confidence to the Virchow and the Pasteur of the future.

THE VALUE OF CLINICAL MICROSCOPY,
BACTERIOLOGY, AND CHEMISTRY
IN SURGICAL PRACTICE,

BEING THE ORATION IN SURGERY BEFORE THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ST. PAUL
JUNE 4, 5, 6, AND 7, 1901.

BY JOHN A. WYETH, M.D.,

NEW YORK.

FOR many years, almost without exception, my predecessors in the address in surgery have devoted their labors to the exposition of some general or special subject in the domain of operative surgery, and, while I would in no measure detract from the value of a thorough technical knowledge, we should not, in our attention to the *art*, fall short of a proper appreciation of the *science* of surgery.

The experienced surgeon soon learns that it requires more than asepsis and the rapid and skilful performance of an operation to achieve the fullest measure of success; that, although a thorough practical knowledge of regional anatomy is essential in the highest degree to the conscientious fulfilment of the professional obligation, it is equally important that there be called into requisition the invaluable aid which laboratory research alone can give in determining an accurate diagnosis; in indicating the most rational measures of treatment, not only in the preparation of a patient for an operation and in the selection of the safest anæsthetic, but for the post-operative management of the case, and in removing as far as possible all doubts as to the prognosis.

Chemical analysis of the normal and abnormal secretions and excretions of the body, *clinical microscopy*, and *bacteriology* should form a part of the educational requirement of every surgeon. I do not insist that the busy practitioner should attempt to master all the intricate processes of the laboratory, for this is only possible to one who devotes years of patient labor in the fascinating department of science, but he should possess that practical knowledge of the chemistry of the body in health and disease and of clinical microscopy and bacteriology which any diligent student, under a competent teacher and in a properly equipped laboratory, should be able to acquire in a three months' course of study.

The instances are exceptional in practice where this knowledge cannot be applied with great benefit to the patient and with satisfaction to the surgeon. It is naturally of greatest value in the cases where no emergency for immediate operation exists, but its advantages are not wanting in these rarer cases, since it comes to his aid in the post-operative period.

Laboratory research, especially in the department of bacteriology, has placed, not only the medical profession, but the entire human family, under lasting obligations for the great benefits which have already been derived from its discoveries, and it may be safely said that it has done more than all else in accomplishing the revolution

in surgical thought and practice which has taken place within the last two decades. One of the most notable illustrations of this great advance is the triumph which has been achieved over that once fatal disease, diphtheria.

The discovery by Klebs, in 1883, and the isolation and cultivation in 1884 by Loeffler, of the bacillus of diphtheria had its logical sequence in Behring's invaluable discovery (subsequently elaborated by Roux) that the blood of animals, especially that of the horse, rendered immune to diphtheria by inoculation, first with attenuated and then with more virulent organisms, contained a substance capable of neutralizing the effects of the bacilli or their *toxine* when simultaneously or subsequently inoculated in non-protected animals.

This antitoxine serum in its dose of 10 c.c. of either the 600, 1,000, or 1,500 *immunizing units* is potent, not only to arrest the destructive processes which formerly characterized this disease, but to prevent the infection of those who have been exposed to the contagion. How great is the importance of the knowledge not only that these bacilli are always present in the throat of a patient suffering from diphtheria, but that they are frequently found on the nasopharyngeal surfaces and tonsils of persons free from systemic infection, and as shown by Biggs, Parke, and Beebe, of New York, they may remain as long as five weeks after the membrane has been discharged from infected subjects, all of which points to the necessity for the isolation of the infected individual and the careful disinfection of the throats of those who have been about diphtheria cases (McFarland).

The statistics of Professor Welch, of Johns Hopkins University, show that the ratio of mortality as a result of these discoveries has been reduced more than 55 per cent., and that in 115 cases, in which by reason of an early diagnosis the treatment of serum antitoxine was begun within the first three days of the disease, the mortality was only 8.5 per cent. In 546 cases in which the remedy was begun after the third day of the disease the mortality was 27.8 per cent., the ratio of mortality increasing with fatal precision as treatment was delayed.

To the surgeon, one of the most gratifying results of this great triumph of the laboratory is the fact that he is now rarely called upon to perform the operation of tracheotomy, which was formerly distressingly frequent, nor to witness the sufferings associated with intubation of the larynx. A professional friend in the department of diseases of children informed me recently that, whereas a few years ago he had from ten to twenty intubations of the larynx on account of diphtheria in every month, he now, since the serum therapy was practised, averaged only one or two.

I believe that what is true of this disease is true of all infectious processes, and that as our knowledge expands a safe immunizing serum will be discovered for each special toxæmia. Even now it would seem that this proposition is proved in other infections in which, like diphtheria, the pathogenic organisms are localized at the seat

of infection, their toxic products alone entering the tissues through the circulation.

Of this type is the spirillum, or "comma" bacillus, discovered by Koch in 1884 in the intestinal contents of patients suffering from Asiatic cholera. These germs are not found in the deeper organs, the morbid changes in the tissues being due to their toxine. Immunizing injections of cholera cultures have already been experimentally and successfully employed, and promise rich results.

In this same group, bacteriologists claim a place for the *Diplococcus micrococcus lanceolatus* of Fraenkel, the pneumococcus. Sternberg and Pasteur isolated this germ in 1880, and in 1884 Fraenkel demonstrated it as the prevailing organism found in the sputum of croupous pneumonia. Very late investigations give encouragement to the hope that serum therapy will soon be applied in the early arrest of the invasion of this most painful and fatal malady. Though pneumonia is strictly a medical disease, its early recognition as a surgical complication, or in view of an anticipated operation, is of very great importance. In a recent case which came under my observation at our laboratory, a specimen of sputum was sent in for bacteriological study. It was not blood-stained or "brick-dust," but yellowish-white in color, like the ordinary sputum of bronchitis, and was supposed to be "grippe" or tuberculosis. The bacillus of tuberculosis was not present, but numerous micrococci lanceolati were discovered, and the laboratory diagnosis was made and confirmed within twenty-four hours by the well-recognized symptoms of consolidation with the "brick-dust" expectoration of this disease which supervened.

Tetanus toxæmia, or "lockjaw," the organism producing which was discovered by Nicolaier in 1894, and which for years has baffled the most strenuous efforts of the bacteriologist and clinician, seems at last to be classified with the controllable infections. Professor Osler, in the last edition of his *Practice of Medicine*, says the immunizing serum of Tizzoni has been successfully and encouragingly employed in doses of 2.25 grammes for the first dose, and 0.6 gramme for subsequent doses. Of 113 patients treated by this method 63 per cent. recovered.

It was not until the discovery of the bacillus of typhoid by Eberth in 1880, and the pure cultures of this germ secured by Gaffky in 1884, that there was made possible in the vast majority of cases of typhoid fever a positive diagnosis.

The demonstration of Widal that when ten drops of a twenty-four-hour bouillon culture of the bacilli typhi were added and thoroughly mixed with one or two drops of serum from the blood of a typhoid patient, the bacilli lost their motility and became agglutinated in masses, was one of the most brilliant advances in clinical bacteriology, and of great value in surgical diagnosis.

In many of the lesions of the abdominal viscera, and especially in those located in that battle-ground of surgery, the right iliac fossa, where the physical signs and the febrile movement may suggest either beginning typhoid, intestinal toxæmia, or a pyogenic sepsis, an early

diagnosis may be determined in no other way than by the aid of the laboratory.

The practitioner who has not called into requisition the invaluable aid which bacteriology affords in the differentiation of those too often obscure intraperitoneal lesions cannot appreciate the satisfaction which this practical application affords. How often the safety of a patient hangs upon even a few hours' time, and, alas! how often this precious time is wasted in the uncertainties of diagnosis, when a resort to the demonstration of science, available to all, would have plainly indicated the proper method of procedure. We know too well the fallacy of relying upon the ordinary subjective symptoms, and even some of the objective symptoms afford us no accurate clue to the pathological process which may exist. The pulse and the temperature of commencing typhoid may well be mistaken for the pulse and temperature of an appendicitis. The pain and muscular resistance over the right iliac and the right abdominal region are in many instances practically alike. The nausea, the vomiting, and the general sense of uneasiness point neither directly to the one nor to the other disease, but in a crucial test by Widal's reaction, with the blood count pointing to the presence or absence of a leucocytosis, the question is quickly settled. I have seen all the symptoms of appendicitis present in cases in which the blood count contradicted a pyogenic sepsis, and in which Widal's reaction told the story of typhoid. On the contrary, I have dealt with cases which ordinarily would have been most perplexing, in which all the symptoms of typhoid prevailed at a period when it was too early to recognize this disease by Widal's test, and a leucocytosis of from 15,000 to 21,000 proved at the earliest possible moment that the case was one for immediate operation.*

*Two of the cases occurring in my own work within the last few months may emphasize the great value of this technique.

A man of thirty was seized with quite severe pains which were confined to the region of the cæcum and appendix. Upon palpation there was well-marked resistance in the muscles immediately over these organs, which was not observed in any other part of the abdominal wall. He had vomited on one or two occasions and the temperature ranged from 101° to 103° F. on the second day of this attack. The questions which were presented to the consultants were whether this temperature could be accounted for by intestinal toxæmia, by appendicitis, or incipient typhoid. Although it was too early in the history of a typhoid case to encourage the belief that Widal's reaction would be present, this was made, and with negative results. On the following day, the symptoms still pointing toward typhoid fever, a careful blood count was made and the leucocytes did not count over 7,000. Assured from this that no dangerous pyogenic process was present, the idea of operation, even exploratory, was abandoned until the examination might be repeated on the succeeding day. A second careful blood count showed no leucocytosis, and on the fourth day, although Widal's reaction was still absent, the case was declared to be typhoid, and the subsequent history proved the diagnosis to be correct, since a few days later the reaction of typhoid was present, and the patient went through the regular stages of this fever.

In a second case, a male patient, forty-five years of age, there was a typical typhoid tongue, temperature ranged from 100° to 103.5° F., tenderness and muscular resistance in the right iliac fossa and loose discharges from the bowels not unlike those frequently met with in typhoid. Widal's reaction was tried with negative results on three successive days. The blood count on the fifth day showed the leucocytes numbering 21,000, justifying a diagnosis which excluded typhoid, and confirmed the suspicion of pyogenic sepsis.

The discovery by Bollinger, in 1877, made the diagnosis of that comparatively rare affection, actinomycosis, clear. In examining the yellow granules and accompanying pus discharged from an infected area he recognized the ray fungus, or actinomyces. More recent researches have shown this fungus to be composed of bacilli in various stages of development, some being spores and some more perfectly developed organisms.

In another fortunately rare disease, malignant pustule, caused by the lodgment in an abrasion of the *Bacillus anthracis*, we are indebted to the laboratory for our knowledge of its ætiology. The anthrax bacillus discovered by Davaine in 1863 is not usually found in the blood except in the most malignant cases and in the last stages of fatal infection, but it can be demonstrated in the pustule of inoculation with the microscope or by cultures.

Roux and Chamberland, according to McFarland, have found that filtered cultures will produce immunity when properly introduced into animals, and we reasonably hope from these experiments that the serum treatment will before long be made applicable to infected human beings.

Another rare organism is the bacillus of malignant œdema, which was discovered by Pasteur in 1875 and called by him *vibrion septique*. There are only two cases of this disease so far reported in man, and they were subjects of abnormally low resistance infected by the hypodermic administration of a product of musk.

The *Bacillus pestis*, or bubonic plague organism, was discovered in 1894 simultaneously by Yersin and Kitasato in blood drawn from the finger-tips of infected individuals and in the broken-down lymph glands, and is described by Kitasato as greatly resembling the microorganism of chicken cholera.

Bacteriological research has robbed the puerperal state of much of the anxiety and dread which formerly attended this ordeal, not only in preventing sepsis, but in recognizing the infections already established in time to prevent a general peritonitis or septicæmia. The puerperal uterus or this organ when the seat of non-puerperal endometritis offers an ideal field for bacterial proliferation and invasion, since septic organisms entering the cavity may rapidly penetrate the endometrium and enter the lymph channels, whence they pass into the venous sinuses and lymphatics of the pelvis.

Professor W. R. Pryor, in a paper read before the New York State Medical Association in 1900, says: "Puerperal sepsis, if not rapidly fatal, almost always produces lesions which seriously damage the pelvic organs or the viscera," and that "time is in this serious condition an important element." He recommends the early employment of the Döderlein tube, which, after sterilization, is passed into the uterus, being protected from contact until the fundus is reached. From the serum and débris thus obtained cultures are made, and the character of the operation—either curettage or hysterectomy—determined by the result of bacteriological investigation.

Not only does the laboratory come to our assistance

in the diagnosis of certain obscure surgical lesions of the stomach, but it is still more valuable as an aid in arriving at the exact condition of the digestive functions of this organ, any derangement of which it is at times exceedingly important to correct in order to bring a patient into suitable condition to stand an operation. Thus, it is important to determine in certain instances whether or not free hydrochloric acid exists in this organ, and while the total quantity poured into the stomach in the digestive process cannot be accurately measured, clinical chemistry can closely estimate the total quantity found at a given moment during digestion. The acid-combining power of the proteids is known, and by certain tests it is feasible to estimate sufficiently close for a satisfactory diagnosis the quantity of hydrochloric acid secreted. The small quantity of hydrochloric acid which combines with ingested inorganic elements is lost to gastric digestion, serving as it does its function in this process in the intestines.

It is clear, as stated by Van Valzah and Nisbit, that the hydrochloric acid which combines with the proteids and that which remains free together roughly represent the activity of acid secretion. It is logical, then, to conclude that the quantity of hydrochloric acid loosely combined with albumin, together with the quantity remaining free in the contents withdrawn at the end of a particular time after eating a particular meal, is a practical and clinical measure of the secretive activity of the peptic glands, and of the digestive work of the stomach. All of this is made sufficiently exact for practical purposes by the laboratory method of analysis after the simple test breakfast of Ewald and Boas or the more elaborate test meal as recommended by Germain-Sée.*

*The simplest method is that known as the test breakfast of Ewald and Boas in which on an empty stomach, usually in the early morning, a breakfast roll which contains about 5 grammes of proteids, 39 grammes of carbohydrates, $\frac{1}{3}$ of a gramme of fat and $\frac{3}{4}$ of a gramme of ash, and weighs 70 grammes and 350 c.c. of water (about a glass and a half) are taken. The bread should be thoroughly chewed and insalivated before being swallowed with the water. Usually in one hour's time a tube is introduced and the contents of the stomach withdrawn, usually by expression, or by siphonage and then filtered. An estimate of the acidity of the filtered contents is made by using a decinormal solution of potash or soda. The number of c.c. of this solution which will neutralize 100 c.c. of the filtered contents of the stomach expresses in figures the acidity of the fluid withdrawn. At the end of an hour, under approximately normal conditions of digestion, the total acidity should be 50 to 60, the hydrochloric acid albumin 30 to 40, the free hydrochloric acid 10 to 20. Any departure from this rule shows the abnormal absence or excess of this important agent.

The test meal of Germain-Sée is at times preferable, since it contains a larger quantity of proteids than the test breakfast of Ewald and Boas just given, but the method of procedure is practically the same. The presence of hydrochloric acid can be recognized by Gunzborg's reagent which is composed of:

Phloroglucin	2 grammes;
Vanillin	1 gramme;
Alcohol (absolute)	30 grammes.

By spreading three or four drops of this reagent in a porcelain crucible, adding upon this the same quantity of the filtered contents, and slowly warming the crucible, after several seconds a red color appears, and at times the red crystals of free hydrochloric acid are seen. Or the simpler method of employing a filtered paper which has been soaked in a 0.5 per cent. alcoholic solution of diamethylamidazo-benzol and dried. This in the presence of a trace of free hydrochloric acid turns distinctly red.

The presence of lactic acid in the stomach contents, as shown by Kelling's test,* has a distinct diagnostic value, since it takes place in comparatively rare conditions, and since these conditions are seldom fulfilled except when carcinoma is present.

Lactic acid is dependent upon the presence of a special bacillus which thrives in the stomach under abnormal conditions, and is capable of converting glucose and lactose into lactic and carbonic acid. Boas goes so far as to insist that the persistent presence of lactic acid in noteworthy quantity during the digestion of a saucer of oat-meal, chemically free from lactic acid, is a specific sign of carcinoma of the stomach.

While the stomach may, under varying conditions, contain hosts of various bacteria in addition to the one just considered, there are only three others that are of importance as pathogenic organisms. First, the *sarcina ventriculi* (in their usual cube arrangement), which when found indicate insufficiency of the stomach muscle due to non-malignant obstruction. They are not found in carcinoma, since they perish in the presence of lactic acid, which, as we have just shown, is so common in malignant diseases of this organ.

Another micro-organism is the *yeast plant*, also found when motor insufficiency exists. It may be present when the stomach contents are alkaline, neutral, or acid.

The *Bacillus geniculatus* is present under the same conditions which produce the lactic-acid organism and is considered also to be suggestive of carcinoma.

When the presence of blood is suspected in the stomach and is not clearly defined by the microscope, chemistry comes to our aid in its recognition by the glacial acetic acid and ether test.†

A study of the discharges from the rectum is as yet of little value to the surgeon. Beyond the recognition of blood or pus, or cast-off cell elements in certain malignant neoplasms, there is but a single organism which is of real diagnostic value, namely, the amœba of dysentery, described by Lamb in 1859, which is a motile mass of protoplasm about 20 micromillimetres in diameter, containing a single nucleus and one or several vacuoles.

In the differentiation between the pathogenic organisms of specific and non-specific urethritis, microscopy and bacteriology are our only infallible guides. They teach us to eliminate the various bacteria found in the external genital and urinary passages, not bearing directly upon the ætiology of urethritis, and to recognize distinctly the two forms of diplococcus, the gonococcus of Neisser and the pseudo-diplococcus, which, while not

morphologically different from the specific disease-producing organism, can be readily distinguished by special modes of staining as well as by cultures. In the daily routine of practice the exact nature of every suspicious urethral discharge should be subjected to careful scrutiny. The patient is entitled to the satisfaction of a negative result, which is easily demonstrated by staining the smear with methylene blue, which clearly defines both organisms. If no cocci are revealed, all anxiety is put at rest, but if there are present both varieties of these organisms, occupying as they do the protoplasm of the pus corpuscles, a further research and the differentiation of the true form from the false diplococcus is imperative. The pseudo-coccus retains the violet color of the aniline-gentian water violet stain, while with careful laboratory technique the addition of the Bismarck brown brings out the gonococcus, the protoplasm of a single pus corpuscle showing at times both the blue stain of the pseudo-coccus and the diplococcus of Neisser, which retains the brown color.*
